FIVE ISLAND HARBOUR, a bay on the W. coast of Antigua. Lon. 61. 35. W. Lat. 17. 13. N.

FIVE-LEAVED GRASS. See **POTENTILLA**.

FIVELGO, or **FIVELINGO**, a district of Groningen, in Holland and the department of the Eems.

FIUME, or **ST. VEIT**, a populous sea-port of Carniola, on the Adriatic, 38 miles S. of Capo di Istria.

FIUME FREDDO, a town of Naples, in the province of Calabria Citra, 11 miles W. S. W. of Cosenza.

FIXATION, in chemistry, the rendering of any volatile substance fixed, so as not to fly off upon being exposed to a great heat. See **FIXED BODIES**.

FIXED-AIR, an aerial fluid which is disengaged from all substances liable to undergo the vinous fermentation, as well as by mixing alkaline salts and earths with acids. It is a gas which is essentially different in its properties from atmospheric air, as the former is unfit to support either the respiration of animals, or the burning of a candle; being likewise specifically heavier than the common air we breathe. From its acid properties, it has been variously denominated aerial acid, cretaceous acid, or carbonic acid: and from its noxious qualities, it has received the name of mephetic gas. The appellation of fixed air has been applied to it from its readily losing its elastic property, and fixing itself in various bodies, especially those which are of a calcareous nature. Fixed air was first discovered by Dr. Black, who, in consequence of various experiments, found that chalk, and the other earths reducible to quick-lime by calcination, consist of an alkaline earth, which is soluble by itself in water; but which, when combined with a large quantity of fixed-air, becomes insoluble; losing the properties of quick-lime, and assuming the appearance those earths naturally have, when not reduced to a calcareous state. It is now generally called carbonic acid gas, which see.

FIXED BODIES, are those which bear a considerable degree of heat without evaporating, or losing any of their weight. Among these, the most fixed are diamonds, gold, &c. See **DIAMOND**, **GOLD**, &c.

FIXED STARS are such as constantly retain the same position and distance with respect to each other; by which they are distinguished from erratic or wandering stars, which are continually shifting their situation and distances. The fixed stars are what we properly and absolutely call stars; the others are either planets or comets. See **ASTRONOMY**.

FLACCUS, CAIUS VALERIUS, an ancient Latin poet, of whom we have very imperfect accounts remaining. He wrote a poem on the Argonautic expedition; of which, however, he did not live to finish the eighth book, dying at about 30 years of age. John Baptista Pius, an Italian poet, completed the eighth book of the Argonautics; and added two more, from the fourth of Apollonius; which supplement was first added to Aldus's edition in 1523.

FLACOURTIA, in botany, a genus of the class and order diccya polyanthia. Male calyx five-parted; corolla none; stamina very numerous. Female calyx many-leaved; corolla none; germen superior. Styles from 5 to 9. Berry many-celled. There is one species, a small tree of Madagascar, bearing an eatable fruit in some degree resembling a plum.

FLADSTRAND, a sea-port of Denmark, on the E. coast of N. Jutland, in the diocese of Aalborg, 30 miles N. N. E. of Aalborg. Lon. 10. 19. E. Lat. 57. 33. N.

FLADUNGEN, a town of Germany, in the bishopric of Wurzburg, 30 miles N. of Wurzburg.

FLAG, in the army, a small banner of distinction, stuck in the baggage-waggon, to distinguish the baggage of one brigade from another, and of one battalion from another; that they may be mar-

shalled by the waggon-master general according to the rank of their brigades, to avoid the confusion that might otherwise arise.

FLAG, in the marine, a certain banner or standard, by which an admiral is distinguished at sea from the inferior ships of his squadron; also the colours by which one nation is distinguished from another. See **PLATE LXXI**. In the British navy, flags are either red, white, or blue; and are displayed from the top of the main-mast, fore-mast, or mizen-mast, according to the rank of the admiral. When a flag is displayed from the flag-staff on the main-mast, the officer distinguished thereby is known to be an admiral; when from the fore-mast, a vice-admiral; and when from the mizen-mast, a rear-admiral. The first flag in Great Britain is the royal standard, which is only to be hoisted when the king or queen is on board the vessel: the second is that of the anchor of hope, which characterises the lord high admiral, or lords commissioners of the admiralty: and the third is the union flag, in which the crosses of St. George and St. Andrew are blended. This last is appropriated to the admiral of the fleet, who is the first military officer under the lord high-admiral. The next flag after the union is that of the white squadron, at the main-mast head; and the last, which characterises an admiral, is the blue, at the same mast-head. For a vice-admiral, the first flag is the red, the second the white, the third the blue, at the flag staff on the fore-mast. The same order proceeds with regard to the rear-admirals, whose flags are hoisted on the top of the mizen-mast: the lowest flag in our navy is accordingly the blue on the mizen-mast. Besides the national flag, merchant-ships frequently bear less flags on the mizen-mast, with the arms of the city where the master ordinarily resides: and on the fore-mast, with the arms of the place where the person who freights them lives.

FLAG, TO HANG OUT THE WHITE, is to ask quarter; or it shews, when a vessel is arrived on a coast, that it has no hostile intention, but comes to trade, or the like. The red flag is a sign of defiance, and battle.

FLAG, TO HEAVE OUT THE, is to put out or put abroad the flag.

FLAG, TO LOWER, OR STRIKE THE, in the marine, is to pull it down upon the cap, or to take it in, out of respect, or submission, due from all ships or fleets inferior to those any way justly their superiors. To lower or strike the flag in an engagement is a sign of yielding. The way of leading a ship in triumph is to tie the flags to the shrouds, or the gallery, in the hind part of the ship, and let them hang down towards the water, and to tow the vessels by the stern. Livy relates, that this was the way the Romans used those of Carthage.

FLAG-OFFICERS, those who command the several squadrons of a fleet, such as the admirals, vice-admirals, and rear-admirals. The flag-officers in our pay are the admiral, vice-admiral, and rear-admiral, of the white, red, and blue.

FLAG-SHIP, a ship commanded by a general or flag-officer, who has a right to carry a flag, in contradistinction to the secondary vessels under its command.

FLAG-STAVES, are staves set on the heads of the top-gallant-masts, serving to let fly, or unfurl, the flag.

FLAG, in botany, see **IRIS**, and **ACORUS**.

FLAGELLANTES, a sect of wild fanatics who chastised and disciplined themselves with whips in public. This sect rose in Italy, in 1260. Its author was one Rainier a hermit; and it was propagated through almost all the countries of Europe. It was probably no more than the effect of an indiscreet zeal, founded on erroneous ideas of the Deity. A great number of persons of all ages and sexes made processions, walking two by two with their shoulders bare, which they whipped till the blood ran down, to obtain mercy from God, and appease his indignation against the wickedness of the age. They were then called the devout; and having established a superior, he was called the general of the devotion.

FLAGELLARIA, a genus of the hexandria monogynia class and order of plants: petals none; perianthium divided into six segments; fruit a roundish berry, containing a single seed. There are two species, shrubs of the East Indies.

FLAGEOLET, or **FLAJEOLET**, a little flute, used chiefly by shepherds, and country people. It is made of box, or any other hard wood, and sometimes of ivory; and has six holes be-

FLAGS.

sides that at the bottom, the mouth-piece, and that behind the neck.

FLAG-FLOWER. See *ACORUS* and *IRIS*.

FLAIL, [*flagellum*, Latin; *flegel*, German,] the instrument with which grain is beaten out of the ear; the tool of the thrasher.

FLAILS consist of the following parts: 1. The hand-staff, or piece held in the thrasher's hand. 2. The swiple, or that part which strikes out the corn. 3. The caplins, or strong double leathers, made fast to the tops of the hand-staff and swiple. 4. The middle band, being the leather thong, or fish-skin, that ties the caplins together.

FLAIR, in sea language, the seamen say, that the work doth flair over, when a ship is housed in near the water, so that the work hangs over a little too much, and thus is let out broader aloft than the due proportion will allow.

FLAKE, in the cod fishery, a sort of scaffold or platform, made of hurdles, and supported by stanchions, used for drying cod-fish in Newfoundland. These flakes are usually placed near the shores of fishing harbours.

FLAKE, in gardening, a sort of carnation, which is of two colours only, and has very large stripes, all of them going quite through the leaves.

FLAKE, **WHITE**, in painting, lead corroded by the pressing of grapes, or a ceruss prepared by the acid of grapes. It is brought here from Italy; and far surpasses, both with regard to the purity of its whiteness, and the certainty of its standing, all the ceruss or white lead made with us. It is used in oil and varnish painting, for all purposes where a very clean white is required. It should be procured in lumps, as brought over, and levigated by those who use it; as that which the colourmen sell in a prepared state is levigated and mixed up with starch, and often with white lead, and worse sophistications.

FLAMANVILLE, a sea-port of France, in the department of the Channel, 10 miles S. W. of Cherbourg.

FLAMBEAU, a kind of large taper, made of hempen wicks, by pouring melted wax on their top, and letting it run down to the bottom. This done, they lay them to dry; after which they roll them on a table, and join four of them together by means of a red-hot iron; and then pour on more wax, till the flambeau is brought to the size required. Flambeaus are of different lengths, and made either of white or yellow wax. They serve to give light in the streets at night, or on occasion of illuminations.

FLAMBOROUGH, a town of Yorkshire, seated on the N. side of the cape, chiefly inhabited by fishermen.

FLAMBOROUGH HEAD, a cape on the E. coast of Yorkshire, five miles E. of Burlington, and 206 from London. It was the Flemburg of the Saxons; so called from the flames or lights made on it to direct the landing of Ida, who in A. D. 547 joined his countrymen in Britain, with a large reinforcement from Germany, and founded the kingdom of Northumberland. Lon. 0. 4. E. Lat. 54. 9. N.

FLAME, [*flamma*, Lat.] in physiology, the small parts of an inflammable body, that are set on fire, and throw off a quantity of light in every direction, or according to Sir Isaac Newton the flame of a body is only the smoke thereof heated red hot; and the smoke is only the volatile part of the body separated by the fire. When oxygen gas is decomposed slowly, the heat is imperceptible, because the caloric is dissipated as soon as generated. When the decomposition goes on faster, the bodies concerned become sensibly warm. A quicker decomposition of the gas heats the bodies so as to render them red hot, which state is called ignition; and when the process is attended with the production of certain fluids, as hydrogen, &c. and the decomposition of oxygen air affords a sufficient development of caloric, then the fluids themselves are ignited, and decomposed, which constitutes flame, and is thence termed inflammation. When a candle is first lighted, which must be done by the application of actual flame, a degree of heat is given to the wick sufficient to destroy the affinity of its constituent parts; some of the tallow is instantly melted, volatilized, and decomposed, its hydrogen takes fire, and the candle melts. As this is destroyed by combustion another portion melts, rises and supplies its place, and undergoes a like decomposition. In this way combustion is maintained in a candle. The most brilliant flame is exhibited in oxygen gas, and in this flames of different colours may be produced: thus a mixture of nitrate of

strontia and charcoal powder, previously ignited, burns with a rose-coloured flame; one part of boracic acid, and three of charcoal mixed, will burn green: one part of nitrate of barytes and four of charcoal powder burn with a yellow flame: equal parts of nitrate of lime and charcoal powder burn orange-red. Combustion is more perfect, and the light more intense, when the air has a freer access to every part of the flame.

FLAMEN, in Roman antiquity, an order of priests, instituted by Romulus or Numa. They were originally only three, viz. the *Flamen Dialis*, *Martialis*, and *Quirinalis*. The two last, though of high authority, were much inferior to the *Flamen Dialis*. All the three were chosen by the people, and consecrated by the Pontifex Maximus. In latter times several priests of the same order were added to them, but inferior in power. The whole number at last amounted to 15: the three first of whom were senators, and called *Flamines majores*; the other 12 taken from among the people, being denominated *Flamines minores*.

FLAMINIUS, or **FLAMINO**, **MARK ANTHONY**, one of the best Latin poets in the 16th century, of Imola in Italy, son and grandson of very learned men. The pope had chosen him secretary to the council in 1545; but he refused that employment, as he favoured the new opinions, and would not employ his pen in an assembly where he knew these opinions were to be condemned. He wrote notes on the Psalms; paraphrased 30 of them in Latin verse; and wrote letters and poems which are esteemed. He died at Rome in 1550.

FLAMSTED, a town of England, in Hertfordshire, five miles from St. Alban's and Dunstable, on the Verlam, anciently called Verlamstede.

FLAMSTEED, **JOHN**, an eminent English astronomer, born in Derby in 1646. He had early read a great deal of civil and ecclesiastical history; but happening to see John De Sacrobosco's book, *De Sphæra*, he acquired a turn for astronomy, which he afterwards prosecuted with great vigour. In 1674, he wrote an ephemeris, in which he shewed the falsity of astrology; and gave a table of the moon's rising and setting, with the eclipses and apses of the moon and planets to fixed stars. This fell into the hands of Sir Jonas Moore; for whom he made a table of the moon's true southings. In 1674, Sir Jonas having informed him, that a true account of the tides would be highly acceptable to the king, he composed a small ephemeris for his use; and when Sir Jonas shewed the king and duke of York Flamsteed's telescopes and micrometer, he procured a warrant to be king's astronomer, with a salary of 100*l.* a-year. His "*Doctrine of the Sphere*" was published in 1681, in a posthumous work of Sir Jonas Moore, intitled "*A new System of the Mathematics*." In 1684, he was presented to the living of Burstow in Surry, which he enjoyed till he died in 1719. His "*Historia cœlestis Britannica*" was published at London in 1725, in three vols. He likewise composed the British Catalogue of the fixed stars, which contains twice the number that are in the catalogue of Hevelius; see *ASTRONOMY*; to each of which he annexed its longitude, latitude, right ascension, and distance from the pole, together with the variation of right ascension and declination, while the longitude increases a degree. This catalogue, together with most of his observations, were printed on a fine paper and character, at the expence of prince George of Denmark.

FLANDERS, a country of the Netherlands, formerly a considerable county, governed by its own hereditary sovereigns; but now forming part of France. It was bounded on the N. by the United Provinces; on the E. by the late Austrian provinces of Brabant and Hainault; on the S. by Hainault and Artois; and on the W. and N. W. by the German ocean; extending 60 miles in length, and 50 in breadth. It contained 30 cities, a great number of market towns, 1454 villages, and 48 abbeys; besides many colleges, monasteries, &c. The towns are situated so near each other, that the Spaniards, who followed Philip II, supposed the whole country to constitute but one great city. Since that period, it has suffered greatly from the ravages of various wars; and particularly during the present. The climate is temperate and healthy; the soil is very fertile, being watered by many rivers and canals, and producing all kinds of corn, flax, and other vegetables; and the surface is very level, there being not a single hill or rising ground in it. The pastures are excellent, and rear great numbers of fine horses, sheep, and black cattle. The Flemings were

were formerly the principal manufacturers in Europe, and either invented or improved several important arts; particularly weaving figured linens; dyeing cloths; painting in oil colours; curing herrings, &c. Silk cotton and woollen stuffs, camblets, brocades, linens, laces, and tapestry, are still manufactured in great quantities. The laces are reckoned superior to all others. The chief rivers are the Scheldt and the Lys. Before the French revolution it was divided into French, Austrian, and Dutch Flanders.

FLANK, [*flanc*, Fr.] in the manege, the side of a horse between the ribs and haunches. A well flanked horse, is one that has wide and well made ribs, and a good body.

FLANKS OF AN ARMY, are the troops encamped on the right and left, as the flanks of a battalion are the files on the right and left.

FLANK OF A BASTION, in fortification, that part which joins the face to the curtain. See **BASTION** and **FORTIFICATION**.

FLANK, OBLIQUE, or SECOND FLANK, that part of the curtain, from whence the face of the opposite bastion may be discovered.

FLANK, RETIRED, LOW FLANK, or COVERED FLANK, one of the platforms of the cazemate. These retired flanks are a great defence to the opposite bastion, and to the passage of the moat, because the besiegers cannot see nor easily dismount their guns. See **FORTIFICATION**.

FLANKED, [*flanquée*,] in heraldry, is used by the French to express our parti per saltier. Coats, however, makes it to be the same with flanch. See the article **FLANCH**.

FLANKED ANGLE, in fortification, that formed by the two faces of a bastion.

FLANKING ANGLE, or ANGLE OF THE TENAILLE, that composed of the two lines of defence, and pointing towards the curtain. See **TENAILLE** and **FORTIFICATION**.

FLANNAN ISLANDS, or SEVEN HUNTERS, a group of small islands, in the North sea, about 17 miles N. W. of the isle of Lewis.

FLANNEL, or FLANEL, [*gwlanen*, Welsh; from *gwlan*, wool, Davies,] a kind of light, porous, woollen stuff, woven on a loom with two treddles, in a manner similar to blaze. This is unquestionably one of the most useful articles of wearing apparel; and it is much to be regretted, that it is not more generally worn, as we are fully persuaded, that it would be the means of preventing many diseases. The principal objection to the wearing of flannel appears to be, that it irritates the skin, and occasions disagreeable sensations: these, however, continue only for a few days, and the subsequent advantages, thence resulting, amply compensate for such temporary uneasiness. Both young and aged, would derive from it equal advantages. We do not, however, mean to insinuate, that flannel next the skin should be universally and indiscriminately worn by infants and young persons; though it is an ill-founded assertion of its adversaries, that it has a tendency to produce eruptions; as it evidently opens the pores, promotes perspiration, and thus removes the principal cause of cutaneous diseases that originate from an obstructed and irregular state of the skin. But we are fully warranted to assert, from daily experience, that the habitual use of this beneficent texture, has essentially contributed to the recovery of numberless rickety children, not less than to the saving of others who were born of feeble and enervated parents. In short, there is every reason to believe, that a more general adoption of this salutiferous cloth might prevent many fatal inflammations of the throat, breast, lungs, &c. to which the poorer class of people are remarkably liable; and thus preserve the lives of multitudes who now become a prey to our damp and variable climate.

FLAT, in the sea-language. To flat in the fore-sail, is to hail it in by the sheet, near the ship's side as possible; which is done when a ship will not fall off from the wind.

FLATS, in music, a kind of additional notes, which, together with sharps, serve to remedy the defects of musical instruments, wherein temperament is required.

FLAT-POINT, a cape of Borneo, on the S. coast. Lon. 112. 0. E. Lat. 2. 45. S.

FLAT-POINT, a cape of Sumatra, at the S. extremity of the island. Lon. 102. 38. E. Lat. 0. 50. S.

FLATTA, a small island of Scotland, one of the Hebrides; two miles E. of Barra.

FLATTERY, CAPE, a cape on the W. coast of North America. Lon. 135. 30. E. Lat. 48. 15. N.

FLATULENCY, a very common disorder, arising from vapours generated in the stomach and intestines. It occasions distensions, disagreeable sensations, and frequently a considerable degree of pain. Sedentary persons, and those who are of a delicate constitution, especially women, are very liable to attacks of this complaint, which is generally induced by the eating of peas, beans, and other leguminous food. Animal fats, especially those of mutton and veal, if moderately used, with large draughts of liquor immediately after eating them, are apt to turn rancid on the stomach, and to be accompanied with flatulency. The drinking of turbid or feculent liquors, whether new or old, as well as excessive potations of hot tea, produce a similar effect. The habit of the patient likewise contributes towards the generation of these causes; so that in phlegmatic constitutions, where the bowels are of a dry and costive disposition, this complaint is most frequent and painful. See **MEDICINE**.

FLATUS. See **MEDICINE**.

FLAVEL, JOHN, an eminent nonconformist minister, was educated at University college, Oxford; and became minister of Deptford, and afterwards of Dartmouth in Devonshire, where he resided the greater part of his life, and was much admired. Though he was generally respected at Dartmouth; yet, in 1685, the aldermen of that town, attended by the rabble, carried about a ridiculous effigy of him, to which were affixed the Bill of Exclusion and the Covenant. He therefore thought it prudent to withdraw from the town; not knowing what treatment he might meet with from a riotous mob, headed by magistrates who were themselves among the lowest of mankind. Part of his Diary, printed with his Remains, give a high idea of his piety. He died in 1691, aged 61; and after his death, his works, consisting of many pieces of practical divinity, were printed in two vols. folio. Among these, the most famous are, 1. Navigation Spiritualized; 2. Divine Conduct, or the Mysteries of Providence; and, 3. Husbandry Spiritualized; of all which there have been many editions in 8vo.

FLAX, in botany, [*flax*, *flex*, Saxon; *vlas*, Dutch,] the fibrous plant of which the finest thread is made. The fibres of flax cleansed and combed for the spinner. See **LINUM**. This valuable plant thrives most luxuriantly on ground newly broken up; which it ameliorates, if it be sown only every sixth year. The best preparatory crops for flax are those of hemp and potatoes. In the fens of Lincolnshire, hemp is sown the first year, on a good free open soil, that has been well tilled, the soil being properly manured with pigeon's dung; the second year again hemp is cultivated without any manure; and, in the succeeding year followed by Flax. With respect to the quality of linseed, from which flax is propagated, that imported from Riga is generally supposed to be the best, and is sown broad-cast with clover, in the proportion of 2, or 2½ bushels per acre. Experience, however, has evinced, that any other seed would be equally successful, if it were properly kept for six or seven years, before it is sown; for the merchants of Riga frequently import linseed from Germany and other countries, which, after several years, they again furnish the same seed, but at an advanced price. It would farther be an useless practice, to exchange linseed among farmers living at some distance; as it has been observed that it improves, when cultivated in a different soil and climate. See also **LINSEED**. In order to prevent the depredations of birds on this valuable seed, circumspect farmers sow it after sun-set on land well pulverized, and harrow it in early the next morning, before the sun rises. Thus the seed, being moistened by the night's dew, is easily enveloped with earth, and rendered invisible to birds. Another great enemy to the prosperity of the flax-plant, is the parasitical weed called the Great Dodder (which see), or *Cuscuta Europaea*, L. Bechstein communicates the following remedy, by which it may be easily and completely extirpated. To every bushel of linseed, take two drachms of camphor reduced to powder, by adding fifteen drops of spirit of wine; and mix it well with the seed on the evening when it is to be sown. As soon as the crop attains the height of four inches, it will be requisite to weed it; an operation which ought to be performed with the greatest care, that the flax may not be trodden down. If it be allowed to grow longer, the stalks will be so much bent and broken, that they never regain their former straightness. When the weeds are carefully eradicated they

they should be carried off the field, and on no account be suffered to lie in the furrows, because they often strike root again, and thus injure the growth of the flax. This plant becomes ripe when it is in full blossom; but, if it be intended to stand for seed, it will not attain to maturity till the milky juice which it affords is dried up; at which time it is to be pulled, in order to be prepared for the manufacturer. The first process which flax undergoes, is that of rating, or steeping it in water to loosen and separate the rind from the stalk. The early flax is generally watered by laying it in bundles, in a pond or reservoir of soft water, where it is pressed down by stones, or other heavy bodies. In the course of a week, the rind will be sufficiently loosened, when the flax ought to be removed from the water, spread out in the air, and dried. Great skill and precaution are necessary in this part of the operation; for should the flax be left too long in the water, the filaments or threads will become rotten and useless: it will therefore be preferable to take it out rather at an earlier period, than to leave it too long in the pits. Another process is that of dew-ripening; which is performed by spreading the flax on the grass, so that the joint action of the rain and dew produces an effect similar to that of rating. In some parts of Germany, it is never steeped in water, but only exposed for several weeks to the air, rain, and sun; by which it is said to become finer and softer than by any other method. To these operations may be added that of rippling, namely the separating of the seed from the stalk, by passing the flax through a kind of comb before it is rated or watered. These combs are made of iron, the teeth of which are so closely set together, that the heads cannot pass through, and consequently are pulled off. Some cultivators, however, beat the seed out in the field where it grew, instead of rippling, by means of a heavy piece of wood fastened to a bundle; after which it is sifted clean into a large sheet. Many attempts have been made by ingenious persons, to improve flax, or to render it finer, softer, and equal to silk in spinning. In Ireland, this object has, in a great measure, been attained by boiling it for several hours in sea-water, with the addition of a lye made of unslacked lime, and two or three parts of pot-ashes: thus we have seen the coarsest part of flax, or tow, considerably changed in its texture, so as to resemble the finest lint. In the 69th Report of the Economical Society of Leipzig, printed in 1797 (in German), we meet with the following process of converting flax into a silky substance, communicated by Count Harsch, director of the mines in Russia: take pure combed flax, tie it up into rollers covered with white buckram, fasten them with packthread, and deposit them for a fortnight in a damp cellar. Then open the flax, and place it under the cylinders of a common mangle, where it should be rolled over five or six times, in a manner similar to that pursued with linen. Next, the flax should be passed through a fine brass comb. This process of mangling and combing must be repeated a second and third time, but the combs ought to be progressively finer. By such treatment (the Count informs the Society) a very fine, tender, and glossy flax, may be obtained, scarcely inferior to China silk; and though it loses more than one-third of its substance, yet the refuse, or tow, is uncommonly fine, and still useful for the manufacture of ordinary linen. He farther observes, that, after each combing, particularly the first, the filaments appear flat and compressed, but that they recover their roundness by the subsequent operation. Flax thus prepared cannot, by mere contact, or the sense of feeling, be distinguished from silk, and is fit to be manufactured into the finest cambric, and Brabant lace. The utility of flax or linseed, in fattening cattle, is also considerable. Besides these various purposes, flax may also be considered as a manure: for the land on which it is spread, in order to prepare it for housing, is thus in a considerable degree ameliorated: and, if rated flax be laid on a coarse, sour pasture, the nature of the herbage will be totally changed; and the sweetest grasses will in future grow on such indifferent soil. The water, too, in which the flax is immersed, if properly sprinkled on land, by means of watering carts, will produce a very fertilizing effect, and increase its value ten or fifteen shillings per acre. But this water is of so poisonous a nature to cattle, that the practice of macerating or steeping flax, in any pond or running stream, is, by the 33d Henry VIII. c. 17, prohibited under very severe penalties.

FLAX, TOAD. See ANTIRRHINUM.

FLEA, in entomology. See PULEX. Children and females

VOL. II.—NO. 35.

are remarkably liable to the attacks of this little enemy; a circumstance which must be attributed to their more tender skin, their purer blood, longer clothes, and, in some individuals, perhaps to a peculiar state of perspiration. Cleanliness, and frequent sprinkling of the room with a simple decoction of wormwood, will soon exterminate the whole breed of these troublesome vermin; and the best remedy to expel them from bed-clothes, is a bag filled with dry moss, the odour of which is to them extremely offensive. Others cover the floors of the rooms where fleas abound, with the leaves of the alder-tree, while the dew is on the foliage, to which these insects fondly adhere, and thus may be easily destroyed. Mercurial ointment, sulphur, and fumigation with the leaves of penny-royal, or the fresh-gathered foliage of that plant, sewed up in a bag, and laid in the bed, are also remedies pointed out for the expulsion of fleas. Dogs and cats may be effectually secured from the persecutions of these vermin, by occasionally anointing their skin with sweet oil.

FLEAM, [corrupted from *φλεβοτομος*, the instrument used in phlebotomy,] an instrument used to bleed cattle, which is placed on the vein, and then driven by a blow.

FLEAMS, A CASE OF, in farriery, comprehends six sorts of instruments; two hooked ones, called drawers, used for cleaning wounds; a pen-knife; a sharp-pointed lancet for making incisions; and two fleams, one sharp and the other broad-pointed. These last are somewhat like the point of a lancet, fixed in a flat handle, and no longer than is just necessary to open the vein.

FLECHE, a town of France, in the department of Sarthe, seated on the Loir, 21 miles S. S. W. of Mans.

FLECHIER, ESPRIT, bishop of Nismes, one of the most celebrated preachers of his age, was born at Perne in Avignon, in 1632. He was nominated bishop of Lavaur in 1685, and translated to Nismes in 1687; where he founded an academy. His palace was also a kind of academy, where he trained up young orators and authors. He published 1. *Cursus Regius*, a Latin poem; 2. *An History of Theodosius the Great, and Cardinals Ximenes and Commendon*. 3. *Several Sermons*. 4. *Miscellaneous Works*. 5. *Letters, funeral orations, &c.* He died in 1710.

FLECKEREN, an island near the S. coast of Norway, Lon. 8. 18. E. Lat. 58. 4. N.

FLEECE, the covering of wool, shorn off the bodies of sheep. See WOOL.

FLEECE, ORDER OF THE GOLDEN, an order of knighthood instituted by Philip II, duke of Burgundy. These knights at first were twenty-four, besides the duke himself, who reserved the nomination of six more: but Charles V. increased them to fifty. He gave the guardianship of this order to his son Philip king of Spain, since which the Spanish monarchs are chiefs of the order. The knights had three different mantles ordained them at the grand solemnity, the collar and fleece.

FLEECEY-HOSIERY, a very useful kind of manufacture, in which fine fleeces of wool are interwoven into a cotton piece of the common stocking texture. The manufacture is thus described in the specification of the patent granted to Mr. Holland, of Broadstreet, Bloomsbury, in the county of Middlesex. "Having in the common stocking-frame, twisted silk, cotton-yarn, flaxen or hempen thread, worsted or woollen yarn, or any such like twisted or spun materials, begin the work in the common manner of manufacturing hosiery, and having worked one or more course or courses in the common way, begin to add a coating, thus: draw the frame over the arch, and then hang wool or jersey, raw or unspun, upon the beads of the needles, and slide the same off their beads upon their stems, till it comes exactly under the ribs of the sinkers; then sink the jacks and sinkers, and bring forward the frame, till the wool or jersey is drawn under the beads of the needles, and having done this, draw the frame over the arch, and place a thread of spun materials upon the needles (under the ribs of the sinkers), and proceed in finishing the course in the usual way of manufacturing hosiery with spun materials. Any thing manufactured in this way, has, on the one side, the appearance of common hosiery, and on the other side the appearance of raw wool.

FLEET, commonly implies a company of ships of war, belonging to any prince or state; but, sometimes it denotes any number of trading ships, employed in a particular branch of commerce. In sailing, a fleet of men of war is usually divided into three squadrons; the admiral's, the vice-admiral's, and the rear-admiral's squadron,

squadron, all which, being distinguished by their flags and pendants, are to put themselves, and, as near as may be, to keep themselves in their customary places, viz. The admiral, with his squadron, to sail in the van, that so he may lead the way to all the rest in the day-time, by the sight of his flag in the main top-mast-head; and in the night-time, by his lights or lanterns. The vice-admiral and his squadron, is to sail in the centre, or middle of the fleet. The rear-admiral, and the ships of his squadron, to bring up the rear. But sometimes other divisions are made, and those composed of the lighter ships and the best sailors, are placed as wings to the van, centre, and rear. See SQUADRON, ADMIRAL, FLAG, &c. Merchant-fleets generally take their denomination from the place they are bound to, as the Turkey fleet, East-India fleet, &c. These, in time of peace, go in fleets for their mutual aid and assistance: in time of war, besides this security, they likewise procure convoys of men of war, either to escort them to the places whither they are bound, or only a part of the way, to a certain place or latitude, beyond which they are judged out of danger of privateers, &c. See CONVOY.

FLEET is also a noted prison in London, where persons are committed for contempt of the king and his laws, particularly of his courts of justice; or for debt, where any person will not, or is unable to pay his creditors. There are large rules and a warden belonging to the fleet prison, which had its name from the float or fleet of the river or ditch, on the side where it stands.

FLEMINGIANS, or FLANDRIANS, in ecclesiastical history, a sect of rigid Anabaptists, who acquired this name in the 16th century, because most of them were natives of Flanders, by way of distinction from the Waterlandians. In consequence of some dissensions among the Flemings relating to the treatment of excommunicated persons, they were divided into two sects, distinguished by the appellations of Flandrians, and Frieslanders, who differed from each other in their manners and discipline.

FLEMINGS, the natives of Flanders.

FLEMINGTON, a post town of New Jersey, in Hunterdown county, 53 miles N. E. by N. of Philadelphia.

FLEMISH BRICKS, a neat, strong, yellow kind of bricks, brought from Flanders, and commonly used in paving yards, stables, &c. being preferable for such purposes to the common bricks. See BRICK.

FLEN, a town of Sweden, in the province of Sudermania; 22 miles N. N. W. of Nyköping.

FLENSBURG, or FLENSBORG, a sea-port of Denmark, on the E. coast of Sleswick, of which it is the capital. It has a good harbour, a strong citadel, and considerable trade. It lies 16 miles N. of Sleswick. Lon. 9. 47. E. Lat. 54. 53. N.

FLESH, [*caro*,] in anatomy, a fibrous part of an animal body, soft and bloody, being that whereof most of the other parts are composed, and whereby they are connected together: or more properly, it is such parts of the body where the blood-vessels are so small, as only to retain blood enough to preserve their colour red. By chemical analysis it is found that muscular flesh is composed of a great number of fibres or threads, commonly of a reddish or whitish colour; but its appearance is too well known to require any description. Hitherto it has not been subjected to a perfectly accurate chemical analysis. From a variety of experiments and facts, ascertained by Thouvenel and Fourcroy, it appears that the muscles are composed chiefly of fibrin, to which they owe their fibrous structure and their form (see FIBRIN); and that they contain also

2. Albumen
3. Gelatine
4. Extractive
5. Phosphate of soda
6. Phosphate of ammonia
7. Phosphate of lime and carbonate of ditto.

For the discovery of the last ingredients we are indebted to Mr. Hatchett, who found that 500 parts of beef muscle left, after combustion, a residuum of 25.6 parts, consisting chiefly of these salts. When muscles are long boiled in water, Mr. Hatchett found that the greater part of the phosphate of lime; as well as of the alkaline phosphates, was dissolved; for the muscle, after this treatment, when dissolved in nitric acid, yielded scarcely any phosphate of lime; whereas if it was dissolved directly in nitric acid, a precipitate of phosphate of lime was thrown down by ammonia. Hence

it would appear, either that the phosphate of lime is united to gelatine, or that it is rendered soluble by means of it. The carbonate of lime still remains after the action of water, and is converted into oxalate when the muscle is treated with nitric acid. When meat is boiled, it is obvious that the gelatine, the extractive, and a portion of the salts, will be separated, while the coagulated albumen and fibrin will remain in a solid state. Hence the flavour and the nourishing nature of soups is derived from the extractive and gelatine. When meat is roasted, on the other hand, all these substances continue in it, and the taste and odour of the extractive are greatly heightened by the action of the fire. Hence the superior flavour of roasted meat. In a work entitled "*Miscellanea Curiosa*," by Mr. Jones, we find an easy method of preparing flesh-meat, without spices, and with very little salt; yet so as to keep good, and always ready for eating, for two or three years, and in the warmest climates. He gives us this account of the Moorish *Elcholle*, made of beef, mutton, or camel's flesh, but chiefly of beef; which is uniformly cut in long slices, well salted, and suffered to lie twenty-four hours in the pickle. It is then removed from those tubs or jars, into others filled with fresh water; and, when it has lain a night, it is taken out, put on ropes, in the sun and air to dry. When thoroughly dried and hard, it is cut into pieces of two or three inches long, and thrown into a pan, or cauldron, which is kept ready with boiling oil and suet sufficient to cover it: thus it is boiled, till it be very clear and red on cutting it; when it is again taken out and set to drain. After having undergone this process, it stands to cool, while jars are prepared for storing it; at the same time pouring upon it the liquor in which it was fried; and, as soon as it is thoroughly cold, the vessels are closely stopped. Preserved in this manner, it will remain hard, and keep two years; indeed, the hardest is considered as the best and most palatable. Thus it is brought to table by the Moors, who sometimes fry it with eggs and garlic, sometimes stew it and squeeze on it the juice of lemon. It is affirmed to be a very good dish, either hot or cold. Another method of preserving flesh-meat, especially veal and lamb, is practised in Germany, and consists simply in immersing them in skimmed milk, so as to cover the whole joint. In warm weather, the milk should be changed twice the first day, and once in 24 hours; but, in a cool temperature, it is sufficient to renew it every two or three days. Thus, the meat may be kept in a sweet state for several weeks; but it ought to be washed in spring water before it is dressed.—Game and beef, however, cannot be preserved in the same manner, and therefore should be wrapped in a clean linen cloth, and buried in a box filled with dry sand, where it will remain sweet for three weeks, if deposited in an airy, dry, and cool chamber.

FLESH is sometimes used by botanists for the soft pulpy substance of any fruit, inclosed between the outer rind or skin and the seeds or stone; or for that part of a root, fruit, &c. fit to be eaten.

FLETCHER, ANDREW, a political writer, was the son of sir Robert Fletcher, of Saltoun, in Scotland, and born in 1653. He was bred up under the care of Dr. Burnet, afterwards bishop of Salisbury, after which he went abroad. On his return to his own country, he became commissioner for East Lothian in the Scotch parliament, in which he so strongly opposed the court measures, that he found it expedient to withdraw to Holland. In 1685 he landed in the west of England with the duke of Monmouth, but was dismissed for shooting a gentleman who had remonstrated with him for stealing his horse. One of Fletcher's biographers says, that "he was a man of breeding and nice honour, in whose constitution anger was extremely predominant," and this is all the reflection he makes upon the murder. However this murder is denied in a M. S. memoir of the family. After this he was engaged in the Hungarian service against the Turks. At the Revolution he returned to his own country, and was a member of the convention for settling the government of Scotland. He died in London in 1716. His publications, which are wholly political, and filled with the boldest extravagances, were collected into one volume, 8vo. 1732.

FLETCHER, ABRAHAM, an ingenious mathematician, was born at Little Broughton, in Cumberland, in 1714, and bred to his father's business, which was that of a tobacco-pipe-maker. He learned to read and write by his own application, after which he taught himself arithmetic, mathematics, and botany. At the age of thirty he

turned schoolmaster, to which profession he added those of astrologer and doctor, by which means he acquired 3000*l*. He died in 1793. He published a compendium of practical mathematics under the title of the Universal Measurer, 1 vol. 8vo. a work of considerable merit.

FLETCHER JOHN, a pious divine, was a native of Switzerland, and educated at Geneva. He came to England, and was appointed president of lady Huntingdon's seminary of education at Treveeka, in South Wales, but was dismissed from that situation for denying the doctrine of absolute election. He afterwards obtained the vicarage of Madely in Shropshire, where he died in 1785. Mr. Fletcher wrote several excellent tracts against the Calvinists in which he manifests a spirit of meekness, wisdom, and Christian love.

FLETCHER'S NOOK, a cape of the United States, in the district of Main. Lon. 70. 59. W. Lat. 43. 25. N.

FLETEWOOD, WILLIAM, an eminent English lawyer and recorder of London, in the reign of queen Elizabeth. He was very zealous in suppressing mass-houses, and committing Popish priests; but once rushing in upon mass at the Portuguese ambassador's house, he was committed to the Fleet for breach of privilege, but soon released. Mr. Wood says, "he was a learned man, and a good antiquarian." He was a good popular speaker, and wrote well upon government. His principal works are; 1. Annalium tam Regum Edwardi V. Richardi III. and Henrici VII. quam Henrici VIII. 2. A Table of the Reports of Edmund Plowden. 3. The Office of a Justice of Peace. He died about 1593.

FLEVILLEA, in botany, a genus of the hexandria order, and diœcia class of plants. Male calyx and corolla quinquefid; stamina five; the nectarium five converging filaments. Female calyx quinquefid; styli three; apple hard, trilocular, barky.

FLEURANCE, a town of France, in the department of Gers, 13 miles N. of Auch.

FLEURI, or FLEURY, CLAUDE, one of the best French critics and historians of his age, was born at Paris in 1640. He applied himself to the law, was made advocate for the parliament of Paris, and attended the bar nine years: he then entered into orders, and was made preceptor to the princes of Conti. In 1689, Lewis XIV. made him sub-preceptor to the dukes of Burgundy, Anjou, and Berry; and in 1706, he gave him the priory of Argenteuille. In 1716, he was chosen counsellor to Louis XV. and died in 1723. He was the author of a great number of esteemed French works; the principal of which are, 1. An Ecclesiastical History, in 20 volumes, the last of which ends with the year 1414. 2. The Manners of the Israelites. 3. The Manners of the Christians. 4. Institutions of Ecclesiastical Law. 5. An Historical Catechism. 6. On the Choice and Method of Study. 7. The Duties of Masters and Servants, &c.

FLEURY, a town of France, in the department of Saone and Loire, and late province of Burgundy, 30 miles N. of Chalons.

FLEURY, a town of France, in the department of the Straits of Calais, 4½ miles N. W. of St. Pol.

FLEXIBLE, in physics, a term applied to bodies capable of being bent or diverted from their natural figure or direction.

FLEXION, in anatomy, is applied to the motion by which the arm or any other member of the body is bent. It is also applied to the muscles, nerves, &c.

FLEXOR, in anatomy, a name applied to several muscles; which are so called from their office, which is to bend the part to which they belong, in opposition to the extensors, which open or stretch them. See ANATOMY.

FLEXURE OF CURVES, in the higher geometry, is used to signify that a curve is both concave and convex, with respect to a given right-line Ap, or a fixed point P, (Plate LXX. fig. 11.) Thus the curve CMD, having the part CM concave towards Ap or P, and the part MD convex to the same; is said to have a flexure: and the point M which limits the concavity and convexity, is called the point of inflection or contrary flexure.

FLIGHT, is evading the course of justice, by a man's voluntarily withdrawing himself. On an accusation of treason or felony, or even of petty larceny, if the jury find that the party fled for the same, he shall forfeit his goods and chattels, although he be acquitted of the offence; for the very flight itself is an offence, carrying with it a strong presumption of guilt, and is at least an

endeavour to elude and stifle the course of justice prescribed by the law. But now the jury very seldom find the flight; such forfeiture being looked upon, since the vast increase of personal property, as too large a penalty for an offence, to which a man is prompted by the natural love of liberty. 4 Black. 387.

FLIGHT, is also used for the manner, duration, &c. of flying. Almost every kind of bird has its particular flight: the eagle's flight is the highest; the flight of the sparrow-hawk and vulture is noble, and fit for high enterprize and combat. The flight of some birds is low, weak, and transient; the flight of the partridge and pheasant is but of short continuance; that of the dove is laboured; that of the sparrow undulatory, &c. The augurs pretended to foretel future events from the flight of birds. See AUGURY.

FLINT, in geography, the capital of Flintshire, in North Wales, 19½ miles N. W. of London, and 12½ W. N. W. of Chester.

FLINT ISLAND, an island of North America, in the Gulph of St. Lawrence, near the E. coast of Cape Breton. Lon. 59. 40. W. Lat. 46. 10. N.

FLINT RIVER, a river of Georgia.

FLINT, a stone of the siliceous kind, found in pieces of different sizes, and usually of a figure more or less globular, commonly among chalk, and often arranged in order. Its texture is compact. Its fracture smooth, conchoidal. The stones are always covered by a white crust. Specific gravity from 2.55 to 2.63. Colour varies from honey-yellow to brownish-black. Very brittle, and splits into splinters in every direction. Two pieces of flint rubbed smartly together phosphoresce, and emit a peculiar odour. When heated it decrepitates, and becomes white and opaque. When exposed long to the air it often becomes covered with a white crust. A specimen of flint analysed by Klaproth contained,

98.00	silica,
.50	lime,
.25	alumina,
0.25	oxide of iron,
1.00	water.

100.00

Vauquelin obtained from another,

97	silica,
1	alumina and iron.

98

Another specimen analysed by Dolomieu was composed of,

97	silica,
1	alumina, and oxide of iron,
2	water.

100

The whole crust with which flint is enveloped consists of the same ingredients, and a little carbonate of lime. Water is essential to flint; for when it is separated by heat, the stone loses its properties. See SILICA.

FLIX, in geography, a town of Spain, in Catalonia, on the Ebro, 20 miles S. of Lerida.

FLOAT OF A FISHING-LINE, the cork or quill that floats or swims above water. See FISHING.

FLOAT also signifies a certain quantity of timber bound together with rafters, athwart, and put into a river to be conveyed down the stream; and even, sometimes, to carry burdens down a river with the stream.

FLOATAGES, all things floating on the surface of the sea or any water: a word much used in the commissions of water-bailiffs.

FLOAT-BOARDS, boards fixed to water-wheels of undershot mills, serving to receive the impulse of the stream, whereby the wheel is carried round. See MILL and WHEEL. It is no advantage to have too great a number of float-boards; because, when they are all struck by the water in the best manner that can be brought to come against them, the sum of all the impulses will be but equal to the impulse made against one float-board at right angles, by all the water coming out of the penstock through the opening, so as to take place on the float-board. The best rule in this case

is, to have just so many, that each of them may come out of the water as soon as possible, alter it has received and acted with its full impulse. As to the length of the float-board, it may be regulated according to the breadth of the mill.

FLOATING BODIES are those which swim on the surface of a fluid, the most interesting of which are ships and vessels employed in war and commerce, and it is of the utmost consequence to ascertain the stability of such vessels. However operose and difficult (says an able mechanic) the calculations necessary to determine the stability of nautical vessels may, in some cases, be, yet they all depend upon the four following simple and obvious theorems, accompanied with other well known stereometrical and statical principles:

Theorem 1. Every floating body displaces a quantity of the fluid in which it floats, equal to its own weight; and consequently, the specific gravity of the fluid will be to that of the floating body, as the magnitude of the whole is to that of the part immersed.

Theorem 2. Every floating body is impelled downward by its own essential power, acting in the direction of a vertical line passing through the centre of gravity of the whole; and is impelled upward by the re-action of the fluid which supports it, acting in the direction of a vertical line passing through the centre of gravity of the part immersed; therefore, unless these two lines are coincident, the floating body thus impelled must revolve round an axis, either in motion or at rest, until the equilibrium is restored.

Theorem 3. If by any power whatever a vessel be deflected from an upright position, the perpendicular distance between two vertical lines passing through the centres of gravity of the whole, and of the part immersed respectively, will be as the stability of the vessel, and which will be positive, nothing, or negative, according as the metacentre is above, coincident with, or below the centre of gravity of the vessel.

Theorem 4. The common centre of gravity of any system of bodies being given in position, if any one of these bodies be moved from one part of the system to another, the corresponding motion of the common centre of gravity, estimated in any given direction, will be to that of the aforesaid body, estimated in the same direction, as the weight of the body moved is to that of the whole system. From whence it is evident, that in order to ascertain the stability of any vessel, the position of the centres of gravity of the whole, and of that part immersed, must be determined; with which, and the dimensions of the vessel, the line of flotation, and angle of deflection, the stability or power either to right itself or overturn, may be found.

FLOATINGS, in husbandry, the drowning or watering of meadows.

FLOATING OF CHEESE, among housewives, separating the whey from the curd. See **CHEESE**.

FLOOD, a deluge or inundation of waters. See **DELUGE**.

FLOOD, among seamen, is when the tide begins to come up, or the water begins to rise, then they call it young flood; after which it is quarter-flood, half-flood, and high-flood.

FLOOD-MARK, the mark which the sea makes on the shore, at flowing water, and the highest tide: it is also called high-water mark.

FLOOD, HENRY, an eminent orator, poet, and politician, of the 18th century, the son of the Right Hon. Warden Flood, lord chief justice of the King's Bench in Ireland, was born in 1732, and educated in Dublin. In 1749, after attending Dublin college for three years, he spent other two with much advantage under the tuition of Dr. Markham, now Archbishop of York. Besides the acquisition of mathematics and other sciences, he became so complete a master of the Greek, that he read it with as much facility as English. In 1759 and 1761, he was chosen a member of the Irish Parliament, and soon rendered himself conspicuous as the great leader of opposition. The first important measure which he attempted was, an explanation of Poyning's law, by a misconstruction of which, the privy council had assumed a degree of power so unconstitutional, as to render the Irish parliament a mere cypher. By his repeated efforts, the obnoxious part of that law was repealed. He next introduced a bill for limiting the duration of the Irish parliament, which till then had always continued during the life of the king. This measure, after much opposition, he at last effected, under the administration of Lord Townshend, in

1769, when the octennial bill was passed, which first gave Ireland a constitution somewhat resembling the British. In 1775, he was appointed a privy counsellor in both kingdoms, and a vice-treasurer of Ireland; but resigned this office, in 1781; upon which his name was struck out of the list of the privy council. In 1782, the British parliament having repealed this act, 6 Geo. I. c. 5, declaring Ireland subordinate to, and dependent on, the imperial crown of Great Britain, Mr. Flood in two able speeches, insisted, that the simple repeal of this act was no security against similar future claims; and, though he was supported by only three members, in the Irish parliament, yet his doctrine was soon after adopted and ratified by the British parliament, who passed an act renouncing the claim for ever. In November 1783, a violent altercation took place between Mr. Flood and Mr. Grattan, in the course of which Mr. Flood gave a detail of his whole political life; and shewed that he had never once departed from the great principles he had always maintained. He was soon after elected a member of the British parliament for Winchester; and in the subsequent one, for Seaford, which he continued to represent till its dissolution in 1790; soon after which, he died of a pleurisy. His first known production was "Verses on the Death of Frederick Prince of Wales;" in the Oxford collection, 1751. He also wrote an Ode to Fame, translated the 1st Pythian Ode of Pindar, printed in 1785; and several orations of Demosthenes, Æschines, and Cicero; still in MS. Several of his speeches are extant; the last of which, delivered March 4th, 1790, on a parliamentary reform, was celebrated by Mr. Fox, as containing the most rational scheme ever proposed on the subject. He married Lady Frances Beresford, daughter of the Earl of Tyrone, in 1762, but had no issue.

FLOCK, or FLUKE. See **ANCHOR**.

FLOOR, in building, that part of a room we walk on. Floors are of several sorts; some of earth, some of brick, others of stone, of boards, &c. See **PAYMENT**. Carpenters never floor their rooms with boards till the carcass is set up, and also inclosed with walls, lest the weather should injure the flooring. Yet they generally rough-plane their boards for flooring before they begin any thing else about the building, that they may set them by to dry and season, which is done in the most careful manner. The best wood for flooring is the fine yellow deal well seasoned, which, when well laid, will keep its colour for a long while; whereas the white sort becomes black by often washing.

FLOOR OF A SHIP, strictly taken, is only so much of her bottom as she rests on when aground. Such ships as have long, and withal broad floors, lie on the ground with most security, and are not apt to heel, or tilt on one side; whereas others, which are narrow in the floor, or, in the sea-phrase, cranked by the ground, cannot be grounded without danger of being overturned.

FLOORS, EARTHEN, are commonly made of loam, and sometimes, especially to make malt on, of lime, and brook-sand, and gun-dust, or anvil-dust from the forge. Ox blood and fine clay, tempered together, Sir Hugh Plat says, make the finest floor in the world. The manner of making earthen floors for plain country habitations is as follows: Take two-thirds of lime, and one of coal-ashes well sifted, with a small quantity of loam clay; mix the whole together, and temper it well with water, making it up into a heap: let it lie a week or ten days, and then temper it over again. After this, heap it up for three or four days, and repeat the tempering very high, till it become smooth, yielding, tough, and gluey. The ground being then levelled, lay the floor therewith about two and a half or three inches thick, making it smooth with a trowel: the hotter the season is, the better; and when it is thoroughly dried, it will make the best floor for houses, especially malt-houses. Those who would have their floors look better, let them take lime made of rag-stones, well tempered with whites of eggs, covering the floor about half an inch thick with it, before the under flooring is too dry. If this be well done, and thoroughly dried, it will look, when rubbed with a little oil, as transparent as metal or glass. In elegant houses, floors of this nature are made of stucco, or of plaster of Paris beaten and sifted, and mixed with other ingredients.

FLOOR TIMBERS, in a ship, are those parts of a ship's timbers which are placed immediately across the keel, and upon which the bottom of the ship is framed; to these the upper parts of the timbers are united, being only a continuation of floor timbers upwards.

FLORA,

FLORA, the reputed goddess of flowers; she was, according to the poets, the wife of Zephyrus. Her image in the temple of Castor and Pollux was dressed in a close habit, and she held in her hands the flowers of pease and beans.

FLORA, among botanists, is used for a catalogue of the plants and trees growing spontaneously in any particular country or district.

FLORAC, a town of France, in the department of Lozere, near the Tarn, 13½ miles S. of Mende.

FLORAL GAMES, or **FLORALES LUDI**, in antiquity, were games held in honour of Flora. They were celebrated with shameful debaucheries.

FLORALIA, in antiquity, a general name for the feasts, games, and other ceremonies, held in honour of the goddess Flora.

FLOREN, or **FLORENCE**, [so named, says Camden, because made by Florentines,] a gold coin of Edward III. in value six shillings. Every pound weight of standard gold was by act 18 Edw. III. to be coined into 50 Florences, to be current at six shillings each; which made in tale 15 pounds; or into a proportionate number of half Florences or quarter-pieces, by indenture of the mint.

FLORENS, **ST.** a town of France, in the department of Maine and Loire, on the Loire, 20 miles S. W. of Angers.

FLORENCE, the capital of the duchy of Tuscany, and one of the finest cities in Italy. It is surrounded on all sides but one with high hills, which rise insensibly, and at last join with the lofty Apennines. The city is divided into two unequal parts by the Arno, over which there are no fewer than four bridges in sight of each other. The bridge of the Trinita is uncommonly elegant, being built entirely of white marble, and ornamented with four beautiful statues representing the Seasons. The quays, the buildings on each side, and the bridges, render that part of Florence through which the river runs by far the finest. The streets, squares, and front of the palaces, are adorned with a great number of statues; many of them by Michael Angelo, Bandinelli, Donatello, Giovanni di Bologna, Benvenuto, Cellini, &c. Some of the Florentine merchants formerly were men of vast wealth, and lived in a most magnificent manner. One of them, about the middle of the 15th century, built that noble fabric, which, from his name, is still called the Palazzo Pitti. He was ruined by the prodigious expence of this building, which was purchased by the Medici family, and has continued ever since to be the residence of the grand dukes. The gardens belonging to it are on the declivity of an eminence. On the summit there is a fort called Belvidere. From this, and some of the higher walks, there is a complete view of the city, and of the beautiful vale of Arno, in which it stands. This palace has been since enlarged. The furniture is rich and curious, particularly some tables of Florentine work, which are much admired. The most precious ornaments, however, are the paintings. The walls of the Imperial Chamber are painted in fresco, by various painters; the subjects are allegorical, in honour of Lorenzo of Medici, surnamed the Magnificent. The famous gallery attracts every stranger. One of the most interesting parts of it is the series of Roman emperors, from Julius Cæsar to Gallienus, with a considerable number of their empresses. This series is almost complete; but wherever the bust of an emperor is wanting, the place is filled up by that of some other distinguished Roman. The celebrated Venus of Medici, which is esteemed the standard of taste in female beauty and proportion, stands in a room called the Tribunal. The inscription on its base mentions its being made by Cleomenes an Athenian, the son of Apollodorus. It is of white marble, and surrounded by other master-pieces of sculpture, some of which are said to be the works of Praxiteles and other Greek masters. In the same room are many valuable curiosities, besides a collection of admirable pictures by the best masters. There are various other rooms, as the Cabinet of Arts, of Astronomy, of Natural History, of Metals, of Porcelain, of Antiquities, &c. It lies 45 miles S. of Bologna, and 125 N. of Rome. Lon. 11. 15. E. Lat. 43. 47. N.

FLORENNES, a town of France, in the department of the Ourte, 10 miles S. of Charleroy, and 16 S. W. of Namur.

FLORENSAC, a town of France, in the department of Herault, on the Herault, 10½ miles S. of Beziers.

FLORENTIA, in ancient geography, a town of Etruria, now

called Florenza, or Fiorenza, by the Italians, and Florence by the English. See **FLORENCE**.

FLORENTIN, or **ST. FLORENTIN**, a town of France, in the department of Yonne, and late duchy of Burgundy, 15 miles N. E. of Auxerre, and 80 S. E. of Paris.

FLORENTINO, one of the three provinces of Tuscany. The capital is Florence.

FLORES, one of the Azores, so named from the multitude of flowers found growing spontaneously on it. Lon. 31° 11' 22" W. from Greenwich, Lat. 39° 26' 20" N.

FLORET, [*fleurette*, Fr.] a small imperfect flower.

FLORID STYLE, a style too much enriched with figures and flowers of rhetoric. This seems to be the fault of many authors and orators of the present age.

FLORIDA, a country of N. America, bounded on the N. by Georgia, on the E. by the Atlantic, on the S. by the Gulfs of Mexico and Florida, and on the W. by the Mississippi. The climate in summer is extremely hot; in winter commonly temperate, though sometimes the rivers are covered with ice. The soil is fertile, and the country abounds with fruit-trees, many of which being in flower at the time of its discovery gave rise to the name of Florida. Oranges, peaches, plums, mulberries, cocoa-nuts, melons, vines, olives, chestnuts, cabbage-trees, &c. grow naturally in great plenty; as well as cotton, flax, hemp, saffrairs, oaks, palms, pines, cedars, cypresses, &c. Cochineal and indigo also abound; and the coasts furnish great quantities of fish, oysters, &c. The forests abound with most of the wild beasts common in America. The original Indians are numerous and active. Florida is 600 miles long, and 130 broad; lying between 82° and 92° Lon. W. and between 25° and 31° Lat. N. It is divided into East and West.

FLORIDA, GULF OF, lies on the S. E. coast of Florida, between the Gulf of Mexico and the Atlantic.

FLORILEGIUM, or **FLORILEGE**, a name the Latins have given to what the Greeks call *anthologion*, Anthology; viz. a collection of choice pieces, containing the finest and brightest things in their kind.

FLORILEGIUM, or **ANTHOLOGIA**, is particularly used for a breviary, in the Eastern church, compiled by Arcadius, for the convenience of the Greek priests and monks, who cannot carry with them in their travels and pilgrimages, all the volumes wherein their office is dispersed. It contains the general rubrics, psalter, canticles, the horologium, and the office of the feria, &c.

FLORIN, a term sometimes used for a coin, and sometimes for a money of account. As a coin, it is of different values, according to the different metals, and different countries where it is struck. The gold florins are most of them of a very coarse alloy, some of them not exceeding 13 or 14 carats, and none of them 17½. As a money of account, it is used by the Italian, Dutch, and German merchants and bankers, but admits of different divisions in different places. See **MONEY**.

FLORIN, a town of Sardinia, eight miles S. of Sassari.

FLORINIANI, or **FLORIANI**, a sect of heretics, of the second century, so named from its author Florinus. Philastrius says, that they were the same with the Carpophorians. He adds, that they were also called soldiers, milites, quia de militibus fuerunt. St. Irenæus calls them Gnostics; St. Epiphanius, Phibionites; and Theodoret, Borborites, on account of the impurities of their lives, &c. though for what particular reasons it is not easy to say, nor perhaps would it be worth an inquiry.

FLORINUS, or **FLORIANUS**, a heretic of the second century, and a priest of the Roman church, deposed for his errors along with Blastus. He made God the author of evil; or rather asserted, that the things forbidden by God are not evil.

FLORIST, a cultivator of flowers; also applied to an author who writes what is called the flora of any particular place. See **FLORA**.

FLORY, **FLOWRY**, or **FLEURY**, in heraldry, a cross that has the flowers at the end circumflex and turning down; differing from the potence, in as much as the latter stretches out more like that which is called the patee.

FLOS, a Flower, in botany. See **BOTANY**, and **FLOWER**.

FLOS FEMINEUS, a flower which is furnished with the pointal or female organ of generation, but wants the stamina or male organ. Female flowers may be produced apart from the male, either on the

same root or on distinct plants. Birch and mulberry are examples of the first case; willow and poplar of the second.

FLOS MASCULUS, a male flower. By this name, Linnaeus and the sexualists distinguish a flower which contains the stamen, or male organ of generation; but not the stigma or female organ. See **BOTANY**, **DICEIA**, and **MONŒCIA**.

FLOS, in chemistry, the most subtle part of bodies separated from the more gross parts by sublimation in a dry form.

FLOSCULUS, in rhetoric, a flower or ornament of speech. See **FLOWER**.

FLOTA, or **FIOTTA**, a **FLEET**; a name given by the Spaniards to the ships which they send annually from Cadiz to the port of Vera Cruz, to fetch thence the merchandizes gathered in Mexico for Spain.

FLOTILLA, a name given to a number of ships, which get before the rest in their return, and give information of the departure and cargo of the *flota* and galleons.

FLOTSON, or **FLOTSOM**, signifies goods lost by shipwreck; which, with *jetson* and *lagan*, are generally given to the lord admiral, when the owners are not known. See **JETSON** and **LAGAN**.

FLOUNDER, **FLUKE**, or **BUT**, in ichthyology. See **PLEURONECTES**. Flounders may be fished for all day long, either in a swift stream, or in the still deep water; but best in the stream, in April, May, June, and July; the most proper baits are all sorts of worms, wasps, and gentles.

FLOUR, *St.* a town of France in the department of Cantal. It is 45 miles S. of Clermont. Lat. 45° 1' 53" N. Lon 3° 5' 24" E. from Greenwich.

FLOUR, the meal of wheat, rye, &c. finely ground and sifted. We have already stated, that corn is the prey of a variety of insects: when converted into flour, it is subject to the depredations of another race of destroyers, which multiply in it so rapidly, that in a very short time they wholly consume its substance. These insects are of an oblong, slender form; their heads are provided with a kind of proboscis or snout, with which they take in their food; their body is composed of several rings. They do incalculable damage to the flour deposited in magazines for armies or other public uses; and after they have insinuated themselves into any parcel, the only method that can be adopted for saving the whole quantity is, to convert it immediately into bread. In order to prevent such noxious vermin from breeding in flour, this valuable commodity should be kept thoroughly dry, as well as the barrels into which it is packed: with such precautions, if the flour be placed in a cool and airy room, it will be effectually preserved. Sometimes, however, it happens, that though every attention be bestowed on it, flour becomes spirit, or damaged, and thus acquires an unpleasant flavour. This may be remedied by mixing a quantity of ground rice (in proportion of one pound to ten of flour) with the usual quantity of yeast and water; keeping the mixture before the fire for the space of two hours; at the expiration of which time, the whole may be wrought into bread, in the common manner: thus it will be totally divested of its disagreeable flavour. See **BAKING**. The proportion of flour, which a bushel of grain affords, greatly varies. A bushel of Essex wheat, Winchester measure, weigh upon an average about 60lbs., which, when ground, will yield (exclusive of the loss incurred by the grinding and drying) 45½lbs. of the flour called seconds, which alone is used for baking throughout the greater part of England, and which affords the most wholesome, though not the whitest bread. Besides the seconds, such a bushel of wheat yields 13lbs. of pollard and bran: the total loss in grinding seldom exceeds one pound and a half. And when the grinding is performed with care, and the corn of a good quality, the loss is considerably less, as has been evinced by various experiments made to ascertain this point. A correspondent of the Editors of the Supplement to the Encyclopædia Britannica (*Art. BREAD*), states, that he weighed two bushels, Winchester measure, of white and red wheat, the whole of which amounted to 122lbs. This wheat was ground under his own inspection, and yielded 121½lbs. of meal; so that the waste or loss in grinding the two bushels, amounted only to half a pound. The meal was also dressed in his presence, and produced 93½lbs. of seconds, and 25½lbs. of pollard and bran, so that the whole loss in the two bushels, both by grinding and dressing, did not exceed two pounds and a half. The bran and pollard were also dressed in a bolting mill, and produced

	lbs.	oz.
Sharps.....	6	0
Fine Pollard.....	5	8
Coarse ditto.....	7	8
Broad Bran.....	5	8
	24	8

One pound only was thus lost in the bolting, and if the sharps had been sifted, they would have afforded three pounds of good flour. We are inclined to think, from these and similar data, if the price of wheat were given, that of flour might be easily ascertained, and those frauds which are now practised with impunity, could be effectually prevented.

FLOWER, **FLOS**, among botanists and gardeners, the most beautiful part of trees and plants, containing the organs of generation and fructification. See **BOTANY**, and **FLOS**. Flowers, designed for medical use, should be plucked when they are moderately blown, and on a clear day before noon: for conserves, roses must be taken in the bud. Flowers were in great request at the entertainments of the ancients, being provided by the master of the feast, and brought in before the second course; or, as some think, at the beginning of the entertainment. They not only adorned their heads, necks, and breasts, with flowers, but often bestrewed the beds, whereon they lay, and all parts of the room with them. But the head was chiefly regarded. See **GARLAND**. Flowers were likewise used in bedecking tombs.

FLOWER DE LIS, or **FLOWER DE LUCE**, in heraldry, a bearing representing the lily, called the queen of flowers, and the true hieroglyphic of royal majesty; but of late it is become more common, being borne in some coats one, in others three, in others five, and in some semée or spread all over the escutcheon in great numbers. The arms of France, under monarchy, were three flower de lis, or, in a field, azure.

FLOWER DE LUCE, in botany. See **IRIS**.

FLOWER, **GENTLE**. See **AMARANTHUS**.

FLOWERS, METHODS OF PRESERVING. A method of preserving flowers in their natural beauty through the whole year has been much sought after. Some have attempted it by gathering them when dry and not too much opened, and burying them in dry sand; but this, though it preserves their figure well, takes off from the liveliness of their colour. I. Muntingius prefers the following method to all others. Gather the flowers, when they are not yet thoroughly open, in the middle of a dry day: put them into a good earthen vessel glazed within; fill the vessel up to the top with them; and when full sprinkle them over with some good French wine, with a little salt in it; then set them in a cellar, tying down the mouth of the pot. After this they may be taken out at pleasure; and, on setting them in the sun, or within reach of the fire, they will open as if growing naturally; and not only the colour, but the smell also will be preserved. The flowers of plants are by much the most difficult parts of them to preserve in any tolerable degree of perfection; of which we have instances in all the *hortisicci*, or collections of dried plants. In these the leaves, stalks, roots, and seeds, of the plants appear very well preserved, the strong texture of these parts making them always retain their natural form, and the colour in many species naturally remaining. But where these fade, the plant is little worse for use as to the knowing the species by it. But it is very much otherwise in regard to flowers: these are naturally by much the most beautiful parts of the plants to which they belong; but they are so much injured in the common way of drying, that they not only lose but change their colours one into another, by which means they occasion many errors: and they usually also wither up, so as to lose their very form and natural shape. The primrose and cowslip afford remarkable instances of the change of colours in the flowers of dried specimens: for those of this class of plants easily dry in their natural shape; but they lose their yellow, and, instead of it, acquire a fine green colour, much superior to that of the leaves in their most perfect state. The flowers of all the violet kind lose their beautiful blue, and become of a dead white: so that in dried specimens there is no difference between the blue-flowered violet and the white-flowered. II. Sir Robert Southwell has communicated to the world a method of drying plants, by which this defect is proposed to be in a great measure remedied, and all flowers preserved in their natural shape, and many in their natural colours.

For this purpose two plates of iron are to be prepared of the size of a large half-sheet of paper, or larger, for particular occasions: these plates must be made so thick as not to bend; and there must be a hole near every corner for a screw to fasten them close together. When these are prepared, lay in readiness several sheets of paper, and then gather the plants with their flowers when quite perfect. Let this be always done in the middle of a dry day; and then lay the plant and its flower on one of the sheets of paper doubled in half, spreading out all the leaves and petals as nicely as possible. If the stalk is thick, it must be pared or cut in half, so that it may lie flat; and if it is woody, it may be peeled, and only the bark left. When the plant is thus expanded, lay round about it some loose leaves and petals of the flower, which may serve to complete any part that is deficient. When all is thus prepared, lay several sheets of paper over the plant, and as many under it; then put the whole between the iron plates, laying the papers smoothly on one, and laying the other evenly over them: screw them close, and put them into an oven after the bread is drawn, and let them lie there two hours. After that, make a mixture of equal parts of aquafortis and brandy; shake these well together, and when the flowers are taken out of the plates, rub them lightly over with a camel's-hair pencil dipped in this liquor; then lay them upon fresh brown paper, and covering them with some other sheets, press them between this and other papers with a handkerchief till the wet of these liquors is dried wholly away. When the plant is thus far prepared, take the bulk of a nutmeg of gum-dragon; put this into a pint of pure water cold, and let it stand 24 hours; it will in this time be wholly dissolved: then dip a fine hair pencil in this liquor, and with it daub over the back sides of the leaves, and lay them carefully down on a half-sheet of white paper fairly expanded, and press them down with some more papers over these. When the gum-water is fixed, let the pressure and papers be removed, and the whole work is finished. The leaves retain their verdure in this case, and the flowers usually keep their natural colours. Some care, however, must be taken, that the heat of the oven be not too great. When the flowers are thick and bulky, some art may be used to pare off their backs, and dispose the petals in due order; and after this, if any of them are wanting, their places may be supplied with some of the super-numerary ones dried on purpose; and if any of them are only faded, it will be prudent to take them away, and lay down others in their stead: the leaves may be also disposed and mended in the same manner. III. Another method of preserving both flowers and fruit sound throughout the whole year, is also given by the same author. Take saltpetre one pound, Armenian bole two pounds, clean common sand three pounds. Mix all well together; then gather fruit of any kind that is not fully ripe, with the stalk to each; put these in, one by one, into a wide-mouthed glass, laying them in good order. Tie over the top with an oil cloth, and carry them into a dry cellar, and set the whole upon a bed of the prepared matter, of two inches thick, in a box. Fill up the remainder of the box with the same preparation; and let it be four inches thick all over the top of the glass, and all round its sides. Flowers are to be preserved in the same sort of glasses, and in the same manner; and they may be taken up after a whole year as plump and fair as when they were buried.

FLOWERS, in chemistry, generally imply dry bodies reduced into very fine parts, either spontaneously, or by some operation of art; but the term is chiefly applied to volatile solid substances, reduced into a kind of fine meal by sublimation. Some flowers are nothing else than the bodies themselves, which are sublimed entire, without suffering any alteration or decomposition; others are some of the constituent parts of the body subjected to sublimation.

FLOWERS, in heraldry. They are much used in coats of arms; and in general signify hope, or denote human frailty and momentary prosperity.

FLOWERS, in rhetoric, [*flosculi*, Lat.] figures or ornaments of language. See COMPARISON, FIGURE, ORATORY, &c.

FLOWN SHEETS, in the sea language, a ship is said to sail with flown sheets when her sails are not haled home, or close to the blocks. The sheets are flown; that is, they are let loose, or run as far as they will.

FLUATES, in chemistry, salts first discovered by Scheele; they are distinguished by the following properties: 1. When sulphuric

acid is poured upon them, they emit acrid vapours of fluoric acid, which corrode glass. 2. When heated, several of them phosphoresce. 3. They are not decomposed by heat, nor altered by combustibles. 4. They combine with silica by means of heat. Most of them are sparingly soluble in water.

FLUATE OF LIME, FLUOR SPAR. This mineral is found abundantly in different countries, particularly in Derbyshire. It is both amorphous and crystallised. The primitive form of the crystals is the regular octahedron; that of its integrant molecules the regular tetrahedron. The varieties of its crystals hitherto observed amount to nine. These are the primitive octahedron; the cube; the rhomboidal dodecahedron; the cubo-octahedron, which has both the faces of the cube and of the octahedron: the octahedron wanting the edges; the cube wanting the edges, and either one face or two faces in place of each. According to Pelletier, it is composed of

21 lime
15 alumina
31 silica
28 fluoric acid
1 phosphoric acid
1 muriatic acid
1 oxide of iron
1 water

99

FLUELLIN, the herb SPEEDWELL. See ANTIRRHINUM.

FLUENT, in fluxions, the flowing quantity, or that which is continually either increasing, or decreasing, whether line, surface, solid, &c. See FLUXION.

FLUID, in physics, is a term applied to all bodies whose particles easily yield to the least partial pressure, or force impressed. See FLUIDITY and HYDROSTATICS.

FLUID, in physiology, an appellation given to all bodies whose particles easily yield to the least partial pressure, or force impressed. See HYDROSTATICS, and the next article.

FLUIDITY, is that state or affection of bodies in which their parts easily move one among another. All substances in nature, as far as we are acquainted with them, occur in one or other of the three following states; namely, the state of solids, of liquids, or of elastic fluids or vapours. It has been ascertained, that in a vast number of cases, the same substance is capable of existing successively in each of these states. Thus sulphur is usually a solid body; but when heated to 212° it is converted into a liquid; and at a still higher temperature (about 570°), it assumes the form of an elastic vapour of a deep-brown colour. Water also in our climate is usually a liquid; but when cooled down to 32° it is converted into a solid body, and at 212° it assumes the form of an elastic fluid. Most solid bodies may be converted into liquids by heating them sufficiently, and on the other hand, every liquid, except spirit of wine, is convertible into a solid body, by exposing it to a sufficient degree of cold. All liquid bodies may, by heating them, be converted into elastic fluids, and a great many solids are capable of undergoing the same change; and, lastly, the number of elastic fluids which by cold are condensable into liquids or solids, is by no means inconsiderable. These facts have led philosophers to form this general conclusion, "that all bodies, if placed in a temperature sufficiently low, would assume a solid form; that all solids become liquids when sufficiently heated; and that all liquids, when exposed to a certain temperature, assume the form of elastic fluids." The state of bodies then depends upon the temperature in which they are placed; in the lowest temperatures they are all solid, in higher temperatures they are converted into liquids, and in the highest of all they become elastic fluids. The particular temperatures at which bodies undergo those changes are exceedingly various, but they are always constant for the same bodies. Thus we see that heat produces changes on the state of bodies, converting them all, first into liquids, and then elastic fluids.

I. When solid bodies are converted by heat into liquids, the change in some cases takes place at once. There is no interval between solidity and liquidity; but in other cases a very gradual change may be perceived; the solid becomes first soft, and it passes slowly through all the degrees of softness, till at last it becomes perfectly fluid. The conversion of ice into water is an instance

stance of the first change; for in that substance there is no intervening state between solidity and fluidity. The melting of glass, of wax, and of tallow, exhibits instances of the second kind of change; for these bodies pass through every possible degree of softness before they terminate in fluidity. In general, these solid bodies which crystallise or assume regular prismatic figures, have no interval between solidity and fluidity, while those that do not usually assume such shapes have the property of appearing successively in all the intermediate states. Solid bodies never begin to assume a liquid form till they are heated to a certain temperature; this temperature is constant in all. In the first class of bodies it is very well defined; but in the second, though it is equally constant, the exact temperature of fluidity cannot be pointed out with such precision on account of the infinite number of shades of softness through which the bodies pass before they acquire their greatest possible fluidity. But even in these bodies we can easily ascertain that the same temperature always produces the same degree of fluidity. The temperature at which this change from solidity to liquidity takes place, receives different names according to the usual state of the body thus changed. When the body is usually observed in a liquid state, we call the temperature at which it assumes the form of a solid, its freezing point, or congealing point. Thus the temperature in which water becomes ice, is called the freezing point of water; on the other hand, when the body is usually in the state of a solid, we call the temperature at which it liquefies its melting point; thus 212° is the melting point of sulphur, 442° the melting point of tin. The following table contains a list of the melting points of a considerable number of solid bodies:

Substance.	Melting point.
Lead.....	594°
Bismuth.....	576°
Tin.....	442°
Sulphur.....	212°
Wax.....	142°
Spermaceti.....	133°
Phosphorus.....	100°
Tallow.....	92°
Oil of anise.....	50°
Olive-oil.....	36°
Ice.....	32°
Milk.....	30°
Vinegar.....	28°
Blood.....	25°
Oil of bergamot.....	23°
Wines.....	20°
Oil of turpentine.....	14°
Sulphuric acid.....	36°
Mercury.....	39°
Liquid ammonia.....	46°
Ether.....	46°
Nitric acid.....	66°

Before Dr. Black began to deliver his chemical lectures in Glasgow in 1757, it was universally supposed, that solids were converted into liquids by a small addition of heat after they had been once raised to the melting point, and that they returned again to the solid state on a very small diminution of the quantity of heat necessary to keep them at that temperature. An attentive view of the phenomena of liquefaction and solidification gradually led this sagacious philosopher to observe their inconsistency with the then received opinions, and to form another, which he verified by direct experiments, and drew up an account of his theory, and the proofs of it, which was read to a literary society in Glasgow on April 23d, 1762; and every year after he gave a detailed account of the whole doctrine in his lectures. The opinion which he formed was, that when a solid body is converted into a liquid, a much greater quantity of heat enters into it than is perceptible immediately after by the thermometer. This great quantity of heat does not make the body apparently warmer, but it must be thrown into it in order to convert it into a liquid; and this great addition of heat is the principal and most immediate cause of the fluidity induced. On the other hand, when a liquid body assumes the form of a solid, a very great quantity of heat leaves it without sensibly diminishing its temperature; and the state of solidity can-

not be induced without the abstraction of this great quantity of heat. Or, in other words, whenever a solid is converted into a fluid, it combines with a certain dose of caloric, without any augmentation of its temperature; and it is this dose of caloric which occasions the change of the solid into a fluid. When the fluid is converted again into a solid, the dose of caloric leaves it, without any diminution of its temperature; and it is this abstraction which occasions the change. Thus the combination of a certain dose of caloric with ice causes it to become water, and the abstraction of a certain dose of caloric from water causes it to become ice. Water then is a compound of ice and caloric; and in general all fluids are combinations of the solid, to which they may be converted by the application of cold, and a certain dose of caloric. Such is the opinion concerning the cause of fluidity taught by Dr. Black as early as 1762. Its truth was established by the following experiments:

First. If a lump of ice, at the temperature of 22° , is brought into a warm room, in a very short time it is heated to 32° , the freezing point. It then begins to melt; but the process goes on very slowly, and several hours elapse before the whole ice is melted. During the whole of that time its temperature continues at 32° ; yet as it is constantly surrounded by warm air, we have reason to believe that caloric is constantly entering into it. Now as none of this caloric is indicated by the thermometer, what becomes of it, unless it has combined with that portion of the ice which is converted into water, and unless it is the cause of the melting of the ice? Dr. Black took two thin globular glasses, four inches in diameter, and very nearly of the same weight. Both were filled with water; the contents of the one were frozen into a solid mass of ice, the contents of the other were cooled down to 33° ; the two glasses were then suspended in a large room at a distance from all other bodies, the temperature of the air being 47° . In half an hour the thermometer placed in the water-glass rose from 33° to 40° , or 7 degrees; the ice was at first 4 or 5 degrees colder than melting snow, but in a few minutes the thermometer applied to it stood at 32° . The instant of time when it reached that temperature was noted, and the whole left undisturbed for ten hours and a half. At the end of that time the whole ice was melted, except a very small spongy mass, which floated at the top, and disappeared in a few minutes. The temperature of the ice water was 40° . Thus $10\frac{1}{2}$ hours were necessary to melt the ice, and raise the product to the temperature of 40° . During all this time it must have been receiving heat with the same celerity as the water-glass received it during the first half-hour. The whole quantity received then was 21 times 7, or 147; but its temperature was only 40° ; therefore 139 or 140 degrees had been absorbed by the melting ice, and remained concealed in the water into which it had been converted, its presence not being indicated by the thermometer. That caloric, or heat, is actually entering into the ice, is easily ascertained by placing the hand on a thermometer under the vessel containing it. A current of cold air may be perceived descending from it during the whole time of the process. But it will be said, perhaps, that the heat which enters into the ice does not remain there, but is altogether destroyed. This opinion is refuted by the following experiment.

Second. If, when the thermometer is at 22° , we expose a vessel full of water at 52° to the open air, and beside it another vessel full of brine at the same temperature, with thermometers in each, we shall find that both of them gradually lose caloric, and are cooled down to 32° . After this the brine (which does not freeze till cooled down to 0°) continues to cool without interruption, and gradually reaches 22° , the temperature of the air, but the pure water remains stationary at 32° . It freezes, indeed, but very slowly; and during the whole process its temperature is 32° . Now, why should the one liquid refuse all on a sudden to give out caloric and not the other? Is it not much more probable that the water, as it freezes, gradually gives out the heat which it had absorbed during its liquefaction; and that this evolution maintains the temperature of the water at 32° , notwithstanding what it parts with to the air during the whole process? We may easily satisfy ourselves that the water while congealing is constantly imparting heat to the surrounding air; for a delicate thermometer suspended above it is constantly affected by an ascending stream of air less cold than the air around. The following experiment, first made

by Fahrenheit, and afterwards often repeated by Dr. Black and others, affords a palpable evidence, that such an evolution of caloric actually takes place during congelation.

Third. If, when the air is at 22° , we expose to it a quantity of water in a tall beer-glass, with a thermometer in it and covered, the water gradually cools down to 22° without freezing. It is therefore 10° below the freezing point. Things being in this situation, if the water is shaken, part of it instantly freezes into a spongy mass, and the temperature of the whole instantly rises to the freezing point, so that the water has acquired ten degrees of caloric in an instant. Now whence came these ten degrees? Is it not evident that it must have come from that part of the water which was frozen, and consequently that water in the act of freezing gives out caloric? From many experiments made on water in these circumstances, it is found that the quantity of ice which forms suddenly on the agitation of water, cooled down below the freezing point, bears always a constant ratio to the coldness of the liquid before agitation. Thus when water is cooled down to 22° very nearly $\frac{1}{2}$ of the whole freezes; when the previous temperature is 27° , about $\frac{1}{3}$ of the whole freezes. In all cases when water is cooled down below 32° , it loses a portion of the caloric which is necessary to constitute its liquidity. The instant that such water is agitated, one portion of the liquid seizes upon the quantity of caloric in which it is deficient, at the expense of another portion, which of course becomes ice. Thus when water is cooled down to 22° , every particle of it wants 10° of the caloric necessary to keep it in a state of liquidity. Thirteen parts of it seize 10 degrees each from the fourteenth part. These thirteen of course acquire the temperature of 32° ; and the other part, being deprived of $10 \times 13 = 130$, which with the ten degrees that it had lost before constitute 140° , or the whole of the caloric necessary to keep it fluid, assumes of consequence the form of ice.

Fourth. If these experiments should not be considered as sufficient to warrant Dr. Black's conclusion, the following, for which we are indebted to the same philosopher, puts the truth of his opinion beyond the reach of dispute. He mixed together given weights of ice at 32° , and water at 190° of temperature. The ice was melted in a few seconds, and the temperature produced was 53° .

The weight of the ice was 119 half-drachms;

That of the hot water 135

of the mixture 254

of the glass vessel 16

Sixteen parts of glass have the same effect in heating cold bodies, as eight parts of equally hot water. Therefore, instead of the 16 half-drachms of glass, eight of water may be substituted, which makes the hot water amount to 143 half-drachms. In this experiment there were 158 degrees of heat contained in the hot water, to be divided between the ice and the water. Had they been divided equally, and had the whole been afterwards sensible to the thermometer, the water would have retained $\frac{143}{2}$ parts of this heat, and the ice would have received $\frac{119}{2}$ parts: that is to say, the water would have retained 86° , and the ice would have received 72° ; and the temperature after mixture would have been 104° . But the temperature by experiment is found to be only 53° ; the hot water lost 137° , and the ice only received an addition of temperature equal to 21° . But the loss of 18° of temperature in the water is equivalent to the gain of 21° in the ice. Therefore $158 - 18 = 140^{\circ}$ of heat have disappeared altogether from the hot water. These 140° must have entered into the ice, and converted it into water without raising its temperature. In the same manner, if we take any quantity of ice, or, which is the same thing, snow at 32° , and mix it with an equal weight of water at 172° , the snow instantly melts, and the temperature of the mixture is only 32° . Here the water is cooled 140° , while the temperature of the snow is not increased at all; so that 140° degrees of caloric have disappeared. They must have combined with the snow; but they have only melted it, without increasing its temperature. Hence it follows irresistibly, that ice, when it is converted into water, absorbs and combines with 140° of caloric. Water, then, after being cooled down to 32° , cannot freeze till it has parted with 140° of caloric; and ice, after being heated to 32° , cannot melt till it has absorbed 140° of caloric. This is the cause of the extreme slowness of these operations. With regard to water, then, there can be no doubt that it owes its fluidity to the caloric which

it contains, and that the caloric necessary to give fluidity to ice is equal to 140° . To the quantity of caloric which thus occasions the fluidity of solid bodies by combining with them, Dr. Black gave the name of latent heat, because its presence is not indicated by the thermometer; a term sufficiently expressive, but other philosophers have rather chosen to call it caloric of fluidity. Dr. Black and his friends ascertained also, by experiment, that the fluidity of melted wax, tallow, spermaceti, and metals, is owing to the same cause. Landriani proved, that this is the case with sulphur, alum, nitre, and several of the metals; and it has been found to be the case with every substance hitherto examined. We may consider it therefore as a general law, that whenever a solid is converted into a fluid, it combines with caloric, and that this is the cause of its fluidity. From the experiments of Dr. Irvine, it appears that the caloric of fluidity of spermaceti is..... 145°

Bees-wax..... 175°

Tin..... 500°

These are the only substances in which the quantity of caloric, absorbed during fusion, has been ascertained. In all of them we see this rule to hold, that the caloric of fluidity increases with the temperature at which liquidity takes place. Dr. Black has rendered it exceedingly probable also, or rather he has proved by his experiments and observations, that the softness of such bodies as are rendered plastic by heat, depends upon a quantity of latent heat which combines with them. Metals also owe their malleability and ductility to the same cause. Hence the reason why they become hot and brittle when hammered.

II. Thus it appears, that the conversion of solids into liquids, is occasioned by the combination of a dose of caloric with the solid. But there is another change of state still more remarkable, to which bodies are liable when exposed to the action of heat. Almost all liquids, when raised to a certain temperature, gradually assume the form of an elastic fluid, invisible like air, and possessed of the same mechanical properties. Thus water, by boiling, is converted into steam, an invisible fluid, 1800 times more bulky than water, and as elastic as air. These fluids retain their elastic form as long as their temperature remains sufficiently high; but when cooled down again, they lose that form, and are converted into liquids. All liquids, and even a considerable number of solids, are capable of undergoing this change when sufficiently heated. With respect to the temperatures at which liquids undergo this change, they may be all arranged under two divisions. There are some liquids which are gradually converted into elastic fluids at every temperature, while others again never begin to assume that change till their temperature reaches a certain point. Water is a well-known example of the first class of bodies. If an open vessel, filled with water, is carefully examined, we find that the water diminishes in bulk day after day, and at last disappears altogether. If the experiment is made in a vessel sufficiently large, and previously exhausted of air, we shall find that the water will fill the vessel in the state of invisible vapour, in whatever temperature it is placed. Alcohol likewise, and ether, and volatile oils, gradually assume the form of an elastic fluid in all temperatures. But sulphuric acid and the fixed oils never begin to assume the form of vapour till they are raised to a certain temperature. Though left in open vessels they lose no perceptible weight; neither does sulphuric acid lose any weight, though kept ever so long in the temperature of boiling water. When liquids gradually assume the form of elastic fluids in all temperatures, they are said to evaporate spontaneously. The second class of liquids want that property altogether. When all other circumstances are the same, the evaporation of liquids increases with their temperature; and after they are heated to a certain temperature, they assume the form of elastic fluids with great rapidity. If the heat is applied to the bottom of the vessel containing the liquids, as is usually the case, after the whole liquid has acquired this temperature, those particles of it which are next the bottom become an elastic fluid first: they rise up, as they are formed, through the liquid, like air-bubbles, and throw the whole into violent agitation. The liquid is then said to boil. Every particular liquid has a fixed point at which this boiling commences (other things being the same), and this is called the boiling point of the liquid. Thus water begins to boil when raised to 212° . It is remarkable, that after a liquid has begun to boil, it never becomes any hotter, however strong the fire to which it is exposed. A strong heat in-

deed makes it boil more rapidly, but does not increase its temperature. This was first observed by Dr. Hooke. It was observed, when treating of the melting point of solids, that it is capable of being varied considerably by altering the situation of the body. Thus water may be cooled down considerably lower than 32° , without freezing. The boiling point is still less fixed, depending entirely on the degree of pressure to which the liquid to be boiled is exposed. If we diminish the pressure, the liquid boils at a lower temperature; if we increase it, a higher temperature is necessary to produce ebullition. From the experiments of professor Robison, it appears that, in a vacuum, all liquids boil about 145° lower than in the open air under a pressure of 30 inches of mercury; therefore water would boil in vacuo at 67° , and alcohol at 34° . In a Papin's digester, the temperature of water may be raised to 300° , or even 400° , without ebullition: but the instant that this great pressure is removed, the boiling commences with prodigious violence. The elasticity of all the elastic fluids into which liquids are converted by heat, increases with the temperature; and the vapour formed, when the liquid boils in the open air, possesses an elasticity just equal to that of air, or capable at a medium of balancing a column of mercury 30 inches high. The following very important table, drawn up by Mr. Dalton from his own experiments, exhibits the elasticity of steam, or the vapour of water of every temperature, from -40° to 325° . The elasticities of all the temperatures from 32° to 212° were ascertained by experiment; the rest were calculated by observing the rate at which the elasticity increased or diminished according to the temperature.

Mr. Dalton has discovered that the elasticity of every other vapour or steam is precisely the same with that of the steam of water at the same distance from its boiling point. Thus water boils at 212° ; its elasticity at the temperature of 182° , or 30 under its boiling point, we see from the table is 15.86. Alcohol boils at 176° ; the elasticity of the steam of alcohol at 146° , or 30° under its boiling point, is likewise 15.86. This very important discovery enables us to ascertain the elasticity of the vapours of all liquids whatever at any temperature, provided their boiling points are known. We have only to find how many degrees the temperature at which the elasticity required is distant from the boiling point of this liquid. The same number of degrees, added to or subtracted from 212° , gives us a temperature, opposite to which in the above table we shall find the elasticity required. Such are the phenomena of the conversion of liquid into elastic fluids. Dr. Black applied his theory of latent heat to this conversion with great sagacity; and demonstrated, that it is owing to the very same cause as the conversion of solids into liquids; namely, to the combination of a certain dose of caloric with the liquid, without any increase of temperature. The truth of this very important point was established by the following experiments:

First. When a vessel of water is put upon the fire, the water gradually becomes hotter till it reaches 212° ; but afterwards its temperature is not increased. Now caloric must be constantly entering from the fire and combining with the water. But as the water does not become hotter, the caloric must combine with that part of it which flies off in the form of steam; but the temperature of the steam is only 212° ; therefore the caloric combined with it does not increase its temperature. We must conclude, then, that the change of water to steam is owing to the combination of this caloric; for it produces no other change. Dr. Black put some water in a tin-plate vessel upon a red-hot iron. The water was of the temperature 50° ; in four minutes it began to boil, and in 20 minutes it was all boiled off. During the first four minutes it had received 162° , or $40\frac{1}{2}$ per minute. If we suppose that it received as much per minute during the whole process of boiling, the caloric which entered into the water and converted it into steam would amount to $40\frac{1}{2} \times 20 = 810^{\circ}$. This caloric is not indicated by the thermometer, for the temperature of steam is only 212° ; therefore Dr. Black called it latent heat.

Second. Water may be heated in a Papin's digester to 400° without boiling; because the steam is forcibly compressed, and prevented from making its escape. If the mouth of the vessel is suddenly opened while things are in this state, part of the water rushes out in the form of steam, but the greater part still remains in the form of water, and its temperature instantly sinks to 212°; consequently 188° of caloric have suddenly disappeared. This caloric must have been carried off by the steam. Now as only about one-fifth of the water is converted into steam, that steam must contain not only its own 188°, but also the 188° lost by each of the other four parts; that is, it must contain $188^\circ \times 5$, or about 940°. Steam therefore is water combined with at least 940° of caloric, the presence of which is not indicated by the thermometer. This experiment was first made by Dr. Black, and afterwards with more precision by Mr. Watt.

Third. When hot liquids are put under the receiver of an air-pump, and the air is suddenly drawn off, the liquids boil, and their temperature sinks with great rapidity a considerable number of degrees. Thus water, however hot at first, is very soon reduced to the temperature of 70°, and ether becomes suddenly so cold, that it freezes water placed round the vessel which contains it. In these cases the vapour undoubtedly carries off the heat of the liquid; but the temperature of the vapour is never greater than that of the liquid itself; the heat therefore must combine with the vapour, and become latent.

Fourth. If one part of steam at 212° is mixed with nine parts by weight of water at 62°, the steam instantly assumes the form of water, and the temperature after mixture is 178.6°, consequently each of the nine parts of water has received 116.6° of caloric; of course the steam has lost $9 \times 116.6^\circ = 1049.4^\circ$ of caloric. But as the temperature of the steam is diminished by 33.3°, we must subtract this sum. There will remain rather more than 1000°, which is the quantity of caloric which existed in the steam without increasing its temperature. This experiment cannot be made directly; but it may be made by passing a given weight of steam through a metallic worm, surrounded by a given weight of water. The heat acquired by the water indicates the caloric which the steam gives out during its condensation. From the experiments of Mr. Watt made in this manner, it appears that the latent heat of steam amounts to 940°. The experiments of M. Lavoisier make it rather more than 1000°. By the experiments of Dr. Black and his friends, it was ascertained, that not only water, but all other liquids during their conversion into vapour, combine with a dose of caloric, without any change of temperature; and that every kind of elastic fluid, during its conversion into a liquid, gives out a portion of caloric without any change of temperature. Dr. Black's law then is very general, and comprehends every change in the state of a body. The cause of the conversion of a solid into a liquid is the combination of the solid with caloric; that of the conversion of a liquid into an elastic fluid is the combination of the liquid with caloric. Liquids are solids combined with caloric. This law, in its most general form, may be stated as follows: whenever a body changes its state, it either combines with caloric, or separates from caloric. No person will dispute that this is one of the most important discoveries hitherto made in philosophy. Science is indebted for it entirely to the sagacity of Dr. Black. Other philosophers indeed have laid claim to it; but these claims are either without any foundation, or their notions may be traced to Dr. Black's lectures, as their opinions originated many years posterior to the public explanation of Dr. Black's theory in the chemical chairs of Glasgow and Edinburgh.

III. A very considerable number of bodies, both solids and liquids, may be converted into elastic fluids by heat; and as long as the temperature continues sufficiently high, they retain all the mechanical properties of gaseous bodies. It is exceedingly probable, that if we could command a heat sufficiently intense, the same change might be produced on all bodies in nature. This accordingly is the opinion at present admitted by philosophers. But if all bodies are convertible into elastic fluids by heat, it is exceedingly probable that all elastic fluids in their turn might be converted into solids or liquids, if we could expose them to a sufficiently low temperature. In that case, all the gases must be supposed to owe their elasticity to a certain dose of caloric: they must be considered as compounds of caloric with a solid or liquid body. This opinion was first stated by Amontons, and it was supported with

much ingenuity both by Dr. Black and Lavoisier, and his associates. It is at present the prevailing opinion; and it is certainly supported not only by analogy, but by several very striking facts. If its truth be admitted, we must consider all the gases as capable of losing their elasticity by depriving them of their heat: they differ merely from the vapours in the great cold which is necessary to produce this change. Now the fact is, that several of the gases may be condensed into liquids by lowering their temperatures. Oxymuriatic acid gas becomes liquid at a temperature not much under 40°; and at 32° it even forms solid crystals. Ammoniacal gas condenses into a liquid at -45°. None of the other gases have been hitherto condensed. It is well known, that the condensation of vapours is greatly assisted by pressure; but the effect of pressure diminishes as the temperature of vapours increases. It is very likely that pressure would also contribute to assist the condensation of gases. It has been tried without effect indeed in several of them. Thus air has been condensed till it was heavier than water; yet it shewed no disposition to lose its elasticity. But this may be ascribed to the high temperature at which the experiment was made relative to the point at which air would lose its elasticity. At the same time it cannot be denied, that there are several phenomena scarcely reconcilable to this constitution of the gases, ingenious and plausible as it is. One of the most striking is the sudden solidification which ensues when certain gases are mixed together. Thus when ammoniacal gas and muriatic acid gas are mixed, the product is a solid salt; yet the heat evolved is very inconsiderable, if we compare it with the difficulty of condensing these gases separately, and the great cold which they endure before losing their elasticity. In other cases too, gaseous bodies unite, and form a new gas, which retains its elasticity as powerfully as ever. Thus oxygen gas and nitrous gas combined form a new gas, namely, nitric acid, which is permanent till it comes into contact with some body on which it can act.

FLUKE. See PLEURONECTES.

FLUKE, in entomology. See FASCIOLA.

FLUKE OF AN ANCHOR, that part of it which fastens in the ground. See ANCHOR.

FLUKE-WORM. See FASCIOLA.

FLUMET, a town of France, in the department of Mont Blanc, 30 miles N. E. of Chambery, and 31 S. E. of Geneva.

FLUMMERY, a kind of jelly made of oatmeal, in the following manner: steep three large table-spoonfuls of finely ground oatmeal for 24 hours in two quarts of pure water, then pour off the clear fluid, and replace it by three pints of fresh water; strain it through a fine hair-sieve, add to it two spoonfuls of orange-flower water, and one of sugar; boil the whole to the consistence of a hasty pudding, stirring it continually while boiling, till it become perfectly smooth. This preparation affords a grateful and nutritive breakfast to persons liable to costiveness, in consequence of a sedentary life.

FLUOR-SPAR. See FLUATE OF LIME, and the next article. The fluates are principally used for smelting ores, being found to act as very powerful fluxes.

FLUORIC ACID. The mineral called fluor, or fusible spar, and in this country Derbyshire spar, was not properly distinguished from other spars till Margraff published a dissertation on it in the Berlin Transactions for 1768. He first proved, that it contained no sulphuric acid, as had been formerly supposed: he then attempted to decompose it, by mixing together equal quantities of this mineral and sulphuric acid, and distilling them. By this method he obtained a white sublimate, which he supposed to be the fluor itself volatilized by the acid. He observed with astonishment, that the glass retort was corroded, and even pierced with holes. Nothing more was known concerning fluor till Scheele published his experiments three years after, by which he proved that it is composed chiefly of lime and a particular acid, which has been called fluoric acid. The composition of fluoric acid is equally unknown with that of muriatic acid. Mr. Henry tried in vain to decompose it by means of electricity. It is always obtained from fluor spar, in which mineral it is found in abundance. For the investigation of the properties of this acid, we are indebted chiefly to Scheele and Priestley. 1. It may be obtained by putting a quantity of the spar in powder into a retort, pouring over it an equal quantity of sulphuric acid, and then applying a very gentle heat. A gas issues from the beak of the retort, which may be

received

received in the usual manner in glass jars standing over mercury. This gas is fluoric acid. The acid may be obtained dissolved in water by luting to the retort a receiver containing water. The distillation is to be conducted with a very moderate heat, not only to allow the gas to condense, but also to prevent the fluor itself from subliming. After the process, provided a glass retort has been employed, a crust of white earth is found in the receiver, which has all the properties of silica. Scheele supposed that the silica produced was formed of fluoric acid and water; and Bergman adopted the same opinion. But Wiegand and Buccholz shewed that the quantity of silica was exactly equal to what the retort lost in weight; and Meyer completed the proof that it was derived from the glass, by the following experiment. He put into each of three equal cylindrical tin vessels a mixture of three ounces of sulphuric acid and one ounce of fluor, which had been pulverized in a mortar of metal. Into the first he put one ounce of pounded glass; into the second the same quantity of quartz in powder; and into the third nothing. Above each of the vessels he hung a sponge moistened with water, and having covered them, he exposed them to a moderate heat. The sponge in the first cylinder was covered with the crust in half an hour; the sponge in the second in two hours; but no crust was formed in the third, though it was exposed several days. In consequence of this decisive experiment, Bergman gave up his opinion; and wrote an account of Meyer's experiment to Morveau, who was employed in translating his works, to enable him to correct the mistake in his notes. Soon after the discovery of this acid, difficulties and doubts concerning its existence as a peculiar acid were started by some French chemists. To remove these objections, Mr. Scheele instituted and published a new set of experiments; which not only completely established the peculiar nature of the fluoric acid, but once more displayed the unrivalled abilities of the illustrious discoverer.

1. Fluoric acid gas is invisible and elastic like air; it does not maintain combustion, nor can animals breathe it without death. It has a pungent smell, not unlike that of muriatic acid. It is heavier than common air. It corrodes the skin almost instantly.
2. Neither caloric nor light produces any alteration on it.
3. When water is admitted in contact with this gas, it absorbs it rapidly; and if the gas has been obtained by means of glass vessels, it deposits at the same time a quantity of silica. Water absorbs a considerable proportion of this gas, but the precise quantity has not been determined. The compound is usually termed fluoric acid by chemists. It is specifically heavier than water, has an acid taste, reddens vegetable blues, and does not freeze till cooled down to 23°. When heated, the acid gas is easily expelled, except the last portions of it, which adhere with great obstinacy.
4. Neither oxygen gas nor any of the simple combustibles or incombustibles produce any change on fluoric acid, either in the gaseous or liquid state.
5. Fluoric acid gas does not act upon any of the metals, but liquid fluoric acid is capable of oxidizing iron, zinc, copper, and arsenic. It does not act upon gold, platinum, silver, mercury, lead, tin, antimony, cobalt.
6. It combines with alkalies, earths, and metallic oxides, and forms with them salts which are denominated fluates. See FLUATE. The most singular property of fluoric acid is the facility with which it corrodes glass and siliceous bodies, especially when hot, and the ease with which it holds silica in solution even when in the state of gas. This affinity for silica is so great, that the thickest glass vessels can only withstand its action for a short time; and the greatest precautions are scarcely sufficient to obtain it entirely free from siliceous earth.
7. It produces no change, as far as is known, upon any of the acids already described.
8. Its affinities are as follows:

Lime,
Barytes,
Strontian,
Magnesia,
Potass,
Soda,
Ammonia,
Glucina,
Alumina,
Zirconia,
Silica.

10. As fluoric acid produces an insoluble compound with lime, it may be employed with great advantage, as Pelletier has observed, to detect the presence of that earth when held in solution. A

drop or two of the acid causes a milky cloud or precipitate to appear, if any time be present. The property which this acid has of corroding glass, has induced several ingenious men to attempt, by means of it, to engrave, or rather etch, upon glass. The glass is covered completely with wax; and then that part where the letters or figures are to appear is laid bare, by removing the wax. The whole is then exposed for some time to the hot vapours of fluoric acid. This simple process is employed with advantage in writing labels on glass vessels, and in graduating thermometers, and other similar instruments. The discovery is by no means new; it has been shewn by Beckman and Accum, that this acid was employed for that purpose by Henry Swanhard, an artist of Nuremberg, as early as 1670. He seems to have kept his art for some time secret, but the receipt was made public by Pauli in 1725. See ETCHING ON GLASS.

FLUSHING, FLESSINGUE, or VLISSINGEN, a strong sea-port town of Holland in the island of Walcheren, and department of the Meuse, 4 miles S.W. of Middleburg, and 28 N.E. of Ostend. This town together with the whole island was annexed to France by an imperial decree of Dec. 27, 1809. Lat. 51° 26' 37" N. Lon. 3° 34' 9" E. from Greenwich.

FLUSTRA, a genus of worms of the order zoophyta. Animal a polype proceeding from porous shells; stem fixed, foliaceous, membranaceous, consisting of numerous rows of cells united together, and woven like a mat. There are about 18 species. The verticillata is found in the Mediterranean, adhering to fuci.

FLUTE, [*fistula*], an instrument of music, the simplest of all those of the wind kind. It is played on by blowing it with the mouth, and the tones or notes are changed by stopping and opening the holes disposed for that purpose along its side. The ancient fistulae, or flutes, were made of reeds, afterwards of wood, and last of metal.

FLUTE, GERMAN, is an instrument entirely different from the common flute. It is not, like that, put into the mouth to be played, but the end is stopt with a tampon, or plug, and the lower lip is applied to a hole about two inches and a half, or three inches, distant from the end. Although playing the flute is on the Continent more generally practised than in Britain, yet we think it useful to observe, that this exercise is by no means compatible with either young or weak lungs. Indeed, all wind-instruments are in many respects objectionable, because, after blowing forcibly, a large portion of air is suddenly inhaled, and afterwards partially expelled from the lungs, so that they are by this debilitating action continually expanded and relaxed, in a manner very different from that which Nature pursues in the process of respiration.

FLUTE, or FLUYT, (originally perhaps *float*) is a kind of long vessel, with flat ribs, or floor timbers; round behind, and swelled in the middle; serving chiefly for the carrying of provisions in fleets, or squadrons of ships, though it is also used for merchandize.

FLUTES, or FLUTINGS, in architecture, perpendicular channels, or cavities, cut along the shaft of a column, or pilaster. See ARCHITECTURE.

FLUX, in medicine, an extraordinary issue, or evacuation, of some humours of the body. See MEDICINE.

FLUX, in metallurgy, is sometimes used synonymously with fusion: for instance, an ore, or rather matter, is said to be in liquid flux, when it is completely fused. But the word flux is generally used to signify certain saline matters, which facilitate the fusion of ores, and other substances which are difficultly fusible in assays, and in the reductions of ores. We shall here describe the fluxes recommended by Bergman, in vol. ii.

1. The phosphoric acid, or rather the microcosmic salt, as it is called, which contains that acid partly saturated with mineral, partly with ammonia, and loaded besides with much water. This salt, when exposed to the flame, boils and foams violently, with a continual crackling noise, until the water and ammonia have flown off; afterwards it is less agitated, sending forth something like black scoræ arising from the burned gelatinous part: these, however, are soon dispelled, and exhibit a pellucid sphericle encompassed by a beautiful green cloud, which is occasioned by the deflagration of the phosphorus, arising from the extrication of the acid by means of the inflammable matter. The clear globule which remains, upon the removal of the flame, continues longer soft than that formed by borax, and therefore is more fit for the addition of the matter to be dissolved. The ammonia is expelled by the fire; therefore an excess of acid remains

remains in what is left behind, which readily attracts moisture in a cool place. 2. Soda, when put upon charcoal, melts superficially, penetrates the charcoal with a crackling noise, and then disappears. In the spoon it yields a permanent and pellucid sphericle, as long as it is kept fluid by the blue apex of the flames, but when the heat is diminished, it becomes opaque, and assumes a milky colour. It attacks several earthy matters, particularly those of the siliceous kind, but cannot be employed on charcoal. 3. Crystallized borax, exposed to the flame urged by the blow-pipe or charcoal, first becomes opaque, white, and excessively swelled, with various protuberances, or branches proceeding out from it. When the water is expelled, it easily collects itself into a mass, which, when well fused, yields a transparent sphericle, retaining its transparency even after cooling. If calcined borax be employed, the clear sphericle is obtained the sooner. Having provided every thing necessary, the following directions, are next to be attended to.

1. A common tallow candle, not too thick, is generally preferable to a wax candle, or to a lamp. The snuff must not be cut too short, as the wick should bend towards the object. 2. The weaker exterior flame must first be directed upon the object, until its effects are discovered; after which the interior flame must be applied. 3. We must observe with attention whether the matter decrepitates, splits, swells, vegetates, boils, &c. 4. The piece exposed to the flame should scarcely ever exceed the size of a pepper-corn, but ought always to be large enough to be taken up by the forceps. 5. A small piece should be added separately to each of the fluxes; concerning which it must be observed whether it dissolves wholly or only in part; whether this is effected with or without effervescence, quickly or slowly; whether the mass is divided into a powder, or gradually and externally corroded; with what colour the glass is tinged, and whether it becomes opaque, or remains pellucid. Having given these directions, Mr. Bergman proceeds next to consider the subjects proper to be examined by the blowpipe. These he divides into four classes: 1. Saline; 2. Earthy; 3. Inflammable; and 4. Metallic. These subjects are treated at considerable length, in Mr. Bergman's writings, to which we refer the reader. Fixed alkalies, nitre, borax, tartar, and common salt, are the saline matters of which fluxes are generally composed. But the word flux is more particularly applied to mixtures of different proportions of only nitre and tartar; and these fluxes are called by particular names, according to the proportions of these ingredients, as in the following instances:

FLUX, WHITE, is made with equal parts of nitre and of tartar detonated together, by which they are alkalis. The residuum of this detonation is an alkali composed of the alkalies of the nitre and of the tartar, both which are absolutely of the same nature. As the proportion of nitre in this mixture is more than

is sufficient to consume entirely all the inflammable matter of the tartar, the alkali remaining after the detonation is perfectly white, and is therefore called white flux; and as this alkali is made very quickly, it is also called extemporaneous alkali. When a small quantity only of white flux is made, as a few ounces for instance, some nitre always remains undecomposed, and a little of the acid of the tartar, which gives a red, or even a black colour, to some part of the flux; but this does not happen when a large quantity of white flux is made, because then the heat is much greater. This small quantity of undecomposed nitre and tartar which remains in white flux is not hurtful in most of the metallic fusions in which this flux is employed: but if the flux is required perfectly pure, it might easily be disengaged from those extraneous matters by a long and strong calcination, without fusion.

FLUX, CRUDE. By crude flux is meant the mixture of nitre and tartar in any proportions, without detonation. Thus the mixture of equal parts of the two salts used in the preparation of the white flux, or the mixture of one part of nitre and two parts of tartar for the preparation of the black flux, are each of them a crude flux before detonation. It has also been called white flux, from its colour; but this might occasion it to be confounded with the white flux above described. The name, therefore, of crude flux is more convenient. Crude flux is detonated and alkalis during the reductions and fusions in which it is employed; and is then changed into white or black flux, according to the proportions of which it is composed. This detonation produces good effects in these fusions and reductions, if the swelling and extravasation of the detonating matters are guarded against. Accordingly, crude flux may be employed successfully in many operations; as, for instance, in the ordinary operation for procuring the regulus of antimony.

FLUX, BLACK. Black flux is produced from the mixture of two parts of tartar and one part of nitre detonated together. As the quantity of nitre which enters into the composition of this flux is not sufficient to consume all the inflammable matter of the tartar, the alkali which remains after the detonation contains much black matter, of the nature of coal, and is therefore called black flux. This flux is designedly so prepared, that it shall contain a certain quantity of inflammable matter; for it is thereby capable, not only of facilitating the fusion of metallic earths like the white flux, but also of reviving these metals. From this property it is also called reducing flux; the black flux, therefore, or crude flux made with such proportions of the ingredients as to be convertible into black flux, ought always to be used when it is required that metallic matters are at once to be fused and reduced. See FUSION.

FLUXIONS.

HISTORY OF FLUXIONS.

(1.) The doctrine of Fluxions comprehends the arithmetic and analysis of fluxions, and Fluents or flowing quantities. It consists of two principal parts, one called the direct, and the other the inverse method of fluxions; the first of these being the same in effect with the differential calculus, and the last the same with the integral calculus of the foreign mathematicians.

(2.) It has been a matter of much dispute among mathematicians, who was the first inventor of this method of calculation; and two of the most celebrated philosophers of the seventeenth century, have laid claim to the honour of the discovery, viz. Sir Isaac Newton, and Mr. Leibnitz. It appears however certain, that Sir Isaac Newton was the first inventor of the method of fluxions, that he had completed his discovery about the year 1669, and had made use of the method in his *Compendium of Analysis and Quadrature of Curves*, before that time. His attention seems even to have been directed to the subject before the year 1665. But it

was M. Leibnitz that first printed any thing relative to this branch of calculation; for in 1684, he gave the rules of the method in the *Leipsic Acts* of that year, but without demonstrations. These however were soon found out by the two brothers John and James Bernoulli, who applied the calculus with considerable success to a number of difficult problems.

(3.) In 1687, Sir Isaac Newton's *Principia* was published, a work which is almost wholly founded upon the same calculus. The common opinion then was, that Newton and Leibnitz had each invented it about the same time; and in confirmation of this opinion, it was observed, that neither of them made any mention of the other, and that though they agreed in the substance of the thing, yet they differed in their ways of conceiving it, calling it by different names, and using, each, a different notation. However, foreign mathematicians having first learned the method by means of M. Leibnitz's publication, became accustomed to look upon him as the sole, or principal inventor, and were ever after strongly prejudiced in favour of his notation, and mode of conceiving.

6 A

(4.) About

(4.) About the year 1699, Mr. Facio, in a Treatise on the Line of Swiftest Descent, declared that he was obliged to own Newton as the first inventor of the differential calculus, and the first by many years; and that he left the world to judge whether Leibnitz, the second inventor, had taken any thing from him. This precise distinction between the first and second inventor, with the suspicion it insinuated, raised a controversy between M. Leibnitz, supported by the editors of the Leipsic Acts, and the English mathematicians, who declared for Newton; but Sir Isaac himself never appeared on the scene. Writing succeeded each other, at first but slowly on either side, probably on account of the distance of places, but the controversy grew still hotter and hotter, till at length, in the year 1711, Mr. Leibnitz complained to the Royal Society, that Dr. Keil had accused him of publishing the method of fluxions invented by Sir Isaac Newton, under other names and characters. He insisted, that nobody knew better than Sir Isaac himself, that he had stolen nothing from him: and required that Dr. Keil should disavow the ill construction that might be put upon his words.

(5.) The society referred the matter to a committee, who, after due consideration, gave in their report as follows: "That M. Leibnitz was in London in 1673, and kept a correspondence with Mr. Collins, by means of Mr. Oldenburgh, till Sept. 1676, when he returned from Paris to Hanover, by way of London and Amsterdam: that it did not appear that M. Leibnitz knew any thing of the differential calculus before his letter of the 21st June, 1677, which was a year after a copy of a letter written by Newton in 1672, had been sent to Paris to be communicated to him, and above four years after Mr. Collins began to communicate that letter to his correspondents; in which the method of fluxions was sufficiently explained, to let a man of his sagacity into the whole matter; and that Sir Isaac Newton had even invented his method before the year 1669, and consequently 15 years before M. Leibnitz had given any thing on the subject in the Leipsic Acts." From which they concluded, that Dr. Keil had not at all injured M. Leibnitz in what he said.

(6.) It seems beyond doubt, that Newton was the first inventor, but some have been of opinion, that notwithstanding the decision given by the Royal Society, there are strong presumptions of M. Leibnitz having found the method for himself, without being previously acquainted with Newton's invention.

(7.) As the method of fluxions was invented by Sir Isaac Newton, so it was carried by him to a considerable degree of perfection, as may be seen in his Fluxions, and in his Quadrature of Curves. The same has been since farther prosecuted and improved by Maclaurin in his Treatise of Fluxions; by D'Alembert in the Memoires de l'Acad. de Berlin; by Euler in his various writings, as well as his Institutio Calculi Integralis; by Cotes in his Harmonia Mensurarum; by Walmesley in his Analyse des Mesures des Rapports et des Angles, &c. and by different authors, both of this and other countries, as Emerson, Simpson, Landen, Waring, Vince, &c. also, L'Hopital, the Bernoullis, Herman, Riccati, La Grange, Cousin, and many others.

DEFINITIONS, PRINCIPLES, AND NOTATION OF FLUXIONS.

(8.) In the method of fluxions, magnitudes or quantities of every kind, are considered as generated by continued motion, by means of which they increase or decrease; as a line by the motion of a point, a surface by the motion of a line, a solid by the motion of a surface, and an angle by the rotation of one of the lines which contain it: the flux of time being supposed to be always uniform; and since all quantities, when we consider their magnitude only, without regarding their position, figure, and other affections, may be represented by lines, it follows, that quantities of every kind may be considered as generated by motion.

(9.) Any variable quantity thus generated, is called a *Fluent* or *Flowing Quantity*; and the rate, or proportion, according to which any flowing quantity increases at any position or instant, is the *fluxion* of that quantity, at that position or instant. This rate of increase is proportional to the magnitude by which the flowing quantity would be uniformly increased in a given time with the generating celerity continued during that time, which magnitude may therefore be taken as a measure of the fluxion of the variable quantity.

(10.) To illustrate these definitions, suppose a point m , Plate

LXXII, fig. 1; be conceived to move from the position A, and to generate a line AP, by a motion any how regulated; and suppose the celerity of the point m , at any position P, to be such, as would, if from thence it should become, or continue uniform, be sufficient to cause the point to pass uniformly over, the distance Pp in the time allowed for the fluxion, then will the said line Pp represent the fluxion of the fluent or flowing line AP at that position.

(11.) Again, suppose the right line mn , fig. 2, to move, from the position AB, continually parallel to itself with any continued motion, so as to generate the fluent or flowing rectangle ABQP, whilst the point m describes the line AP; also let the distance Pp be taken, as before, to represent the fluxion of the line, or base AP, and complete the rectangle PQqp; then, like as Pp is the fluxion of the line AP, so is Pq the fluxion or flowing parallelogram AQ; for if the line Pp be supposed to be generated with an uniform celerity, in a given time, the parallelogram Pq will also be generated with an uniform celerity in the same time.

(12.) In like manner, if the solid AERP, fig. 3, be conceived to be generated by the plane PQR moving, from the position ABE, always parallel to itself, along the line AD, and if Pp denote the fluxion of the line AP; then, like as the rectangle PQqp expresses the fluxion of the flowing rectangle ABQP, so also shall the fluxion of the variable solid, or prism ABERQP, be expressed by the prism PQRrqp. And in both these last two cases, it appears that the fluxion of the generated rectangle, or prism, is equal to the product of the generating line, or plane, drawn into the fluxion of the line along which it moves.

(13.) Hitherto the generating line or plane has been considered as of a constant or invariable magnitude; in which case the fluent, or quantity generated, is a rectangle or a prism, the former being described by the motion of a line, and the latter by the motion of a plane. So in like manner are other figures, whether plane or solid, conceived to be described by the motion of a variable magnitude, whether it be a line or a plane. Thus, let a variable line PQ, fig. 4, 5, and 6, be carried with a parallel motion along the line AP, so that while the point P generates the line AP, the line PQ may generate the area APQ; by this means the point Q will generate the line AQ, which will be a straight line when PQ as well as AP, flows uniformly, otherwise it will be a curve. Here therefore, there are several fluents or flowing quantities, namely, the absciss or base AP, the perpendicular or ordinate PQ, the area APQ, and the straight line or curve AQ.

(14.) In order to exhibit the fluxions of these quantities: let Pp, as before, be the fluxion of the base, complete the rectangle PQRp, this rectangle will be the measure of the fluxion of the curvilinear area APQ. For if the generating line were supposed to become invariable at the position PQ, it is evident that while the line Pp was described by the point P with an uniform celerity, the parallelogram Pp would also be generated by the line PQ uniformly, and with the very celerity with which the area APQ was increasing at the position PQ. Next suppose that the variable line PQ increases uniformly, after leaving the position PQ, with the very degree of celerity of increase it had when in that position; it is evident that the point Q will now describe a straight line Qq, which, as in fig. 5 and 6, will be a tangent to the curve at Q, this line will also be generated with an uniform celerity, viz. the very celerity with which the generating point was moving in the curve at the position Q. Hence it appears, that as Pp is the measure of the fluxion of the base, or absciss AP, and Pp of the fluxion of the area APQ, so is the line r q, the measure of the fluxion of the ordinate, or generating line PQ, and Qq the measure of the fluxion of the curve line AQ.

(15.) In the doctrine of fluxions, the initial letters of the alphabet, a, b, c, d , &c. are commonly used to denote constant or invariable quantities; and the last letters z, y, x, w , &c. to denote variable or flowing quantities. Thus, the variable line AP, fig. 3, may be represented by x , and the constant line PQ by a ; also, in fig. 5 and 6, the variable absciss AP may be represented by x , the ordinate PQ by y , and the curve line AQ by z .

(16.) The fluxion of a variable quantity denoted by a single letter is represented by the same letter with a point over it. Thus, the fluxion of x is represented by $\dot{x}$, the fluxion of y by $\dot{y}$, &c. therefore in fig. 5, the line Pp or Qr will be represented by $\dot{x}$, the line r q by $\dot{y}$, and Qq by $\dot{z}$. For these fluxions are as their measures

measures, and therefore may be used instead of them. When the fluxion of a quantity is itself variable its fluxion is called the second fluxion of the first quantity, and is denoted by two dots over it; if the second fluxion be variable, its fluxion is the third fluxion and is denoted by three dots over it, &c. $\dot{x}, \ddot{x}, \dddot{x}$, &c. represent the first, second, third, fourth, &c. fluxion of x . The higher orders of fluxions may be illustrated by fig. 4, 5, and 6; where if x denote AP and y , PQ, and if PQ flow along AP uniformly, the fluxion of the absciss AP or $\dot{x}$ is constant, or always the same, or $\dot{x} = 0$, in all the figures, if AQ be a right line, as in fig. 4, then $\dot{y} = r q$, is also constant, for the angle $q Q r =$ the angle A being constant, and the angle $Q r q$, a right angle, also $Q r$, constant, $r q$ is always the same, or $\dot{y} = 0$. But in fig. 5, $r q$, or $\dot{y}$ continually increases; and in fig. 6, decreases more and more, hence in both cases y has a second fluxion, which is positive in fig. 5, and negative in fig. 6.

TO FIND THE FLUXIONS OF FLOWING QUANTITIES, CALLED THE DIRECT METHOD.

(17.) If a variable quantity x be multiplied by a constant quantity a , the fluxion will be $a\dot{x}$. For if x increase uniformly, $a x$ will increase uniformly, and a times as fast, hence the fluxion will be $a\dot{x}$, and thus in all cases the constant multiplier must be retained.

(18.) The fluxion is not altered when a constant quantity is connected to the variable one by the sign plus or minus; thus the fluxion of $x \pm a$ is $\dot{x}$. For since a is constant and only to be added or subtracted, it does not affect the increase or decrease of x .

(19.) The fluxion of the product of two variable quantities, as xy , is the sum of the products of each into the fluxion of the other, as $x\dot{y} + y\dot{x}$. Let AP, fig. 7, be x , and PQ = y ; then BP = xy is the flowing or variable rectangle, and let AD so move on AC, and AC on AD, that the intersection Q may describe the curve AQ, and let Pp represent the fluxion of AP, and Bb of AB or PQ, then $x\dot{y}$ is the fluxion of the trilinear space ABQ, and $y\dot{x}$ that of the space AQP, therefore $x\dot{y} + y\dot{x}$ is the fluxion of the whole rectangle PB, by art. 14. Otherwise. Let the factors of the product x and y , by flowing become $x + \dot{x}$, and $y + \dot{y}$, then the new or contemporaneous value of the flowing product will by multiplication be found equal to $xy + x\dot{y} + y\dot{x} + \dot{x}\dot{y}$; and subtracting the original product xy , the remainder $x\dot{y} + y\dot{x} + \dot{x}\dot{y}$ will be the increment of the product generated in the same time as $\dot{x}$ or $\dot{y}$; but this increment is not uniformly generated, for the part of it denoted by $\dot{x}\dot{y}$ arises from an increase added to that by which the product is uniformly augmented, as may be thus shewn. Let some part as half of the time be taken, then the quantities are

$x + \frac{\dot{x}}{2}$ and $y + \frac{\dot{y}}{2}$, and, as above, the increment of the product

in the same time will be found $\frac{x\dot{y}}{2} + \frac{y\dot{x}}{2} + \frac{\dot{x}\dot{y}}{4}$; in $\frac{1}{4}$ of the time

it is $\frac{x\dot{y}}{4} + \frac{y\dot{x}}{4} + \frac{\dot{x}\dot{y}}{16}$, in $\frac{1}{8}$ it is $\frac{x\dot{y}}{8} + \frac{y\dot{x}}{8} + \frac{\dot{x}\dot{y}}{64}$ &c. Hence it is evident that the part of the increment $x\dot{y} + y\dot{x} + \dot{x}\dot{y}$ has arisen from an uniform increase, and the part $\dot{x}\dot{y}$ has wholly proceeded from an augmentation to that increase, for it continually rises from 0 to $\dot{x}\dot{y}$ in a duplicate ratio; hence had there not been an accelerated increase, the quantity $\dot{x}\dot{y}$ would not have been generated; therefore if we write the fluxions $\dot{y}$ and $\dot{x}$ instead of their measures y and x , we have $x\dot{y} + y\dot{x}$ for the fluxion of xy .

(20.) By means of the above, the fluxions of the continued product of any number of flowing quantities may be found as of xyz , $wxyz$, &c. Put $v = xyz$, and $w = xy$, then $v = wz$, and $\dot{v} = \dot{w}z + w\dot{z}$; and $\dot{w} = \dot{x}y + x\dot{y}$ (art. 19.); and by substituting the values of w and $\dot{w}$, we have $\dot{v} = x\dot{y}z + y\dot{x}z + \dot{x}\dot{y}z$; and in a similar manner the fluxion of $wxyz$ will be found equal to $w\dot{x}y + \dot{w}xy + x\dot{w}y + \dot{x}\dot{w}y$; and thus for any number of factors.

(21.) The fluxion of a fraction $\frac{x}{y}$ is easily determined from that

of a product. Put $\frac{x}{y} = v$, then $x = vy$, and $\dot{x} = v\dot{y} + y\dot{v}$

and $y\dot{v} = \dot{x} - x\dot{y}$, and $\dot{v} = \frac{\dot{x} - x\dot{y}}{y}$, and by substituting the value of v , we have $\dot{v} = \frac{\dot{x} - x\dot{y}}{y} = \frac{\dot{x}}{y} - \frac{x\dot{y}}{y^2}$, the fluxion of $\frac{x}{y}$.

(22.) From art. 19, and 20, the fluxion of the powers of flowing quantities are also determined, for if x and y (art. 19,) be equal, then the product xy becomes x^2 and the fluxion $x\dot{y} + y\dot{x}$ becomes $x\dot{x} + x\dot{x} = 2x\dot{x}$, and thus the fluxion of xyz (art. 20,) is equal to $3x^2\dot{x}$ when each of the factors is equal to x . And in general the fluxion of x^n by the same article is evidently equal to $x^{n-1}\dot{x}$ repeated as often as there are units in n , that is equal to $n x^{n-1} \dot{x}$.

(23.) Hence the fluxion is found when the index is a fraction as of $x^{\frac{n}{m}}$, which put equal y , then $y^m = x^n$, and in fluxions $m y^{m-1} \dot{y} = n x^{n-1} \dot{x}$, and $\dot{y} = \frac{n x^{n-1} \dot{x}}{m y^{m-1}}$ (by substituting the value

of y) $\frac{n x^{n-1} \dot{x}}{m x^{\frac{n}{m}-1}} = \frac{n}{m} x^{\frac{n}{m}} \dot{x}$

(24.) In like manner is the fluxion obtained when the index is negative, as of $x^{-n} = \frac{1}{x^n}$, which put equal y , then is $y x^n = 1$,

and in fluxions $x^n \dot{y} + y n x^{n-1} \dot{x} = 0$, and $\dot{y} = -\frac{y n x^{n-1} \dot{x}}{x^n} = -\frac{y n \dot{x}}{x} =$ (by substituting the value of y) $-\frac{n \dot{x}}{x^{n+1}} = -\frac{n}{x^{n+1}} \dot{x}$.

(25.) The fluxion of the hyperbolic logarithm of any quantity x is equal to $\frac{\dot{x}}{x}$, that is the fluxion of the quantity divided by the quantity itself. Let L be the principal vertex of an hyperbola LV, Plate LXXII. fig. 8, OR and OS the asymptotes, and OA = AL = 1, the parameter, and PM an ordinate parallel to AL. Then from the nature of the hyperbola and of logarithms, the space ALMP is known to be the hyperbolic logarithm of OP; put OP = x , and PM = y , then the fluxion of the space ALMP is equal $y +$ the fluxion of AP, or of $x - 1 = y \dot{x}$, (art. 14, and 18,) = the fluxion of the logarithm of x : but from the nature of the curve OA + AL = OP + PM; hence $1 = xy$, and $y = \frac{1}{x}$, therefore

$y \dot{x} = \frac{\dot{x}}{x}$ = the fluxion of the hyperbolic logarithm of x .

(26.) Let m be the modulus of any other system of logarithms, and let x be the hyperbolic logarithm of any quantity x , then it is well known that $m x$ is the logarithm of x in the proposed system;

but the fluxion of $m x$ is equal to $m \dot{x}$, (art. 17,) and $\dot{x} = \frac{\dot{m x}}{m}$, (art.

25,) hence $m \dot{x} = \frac{m \dot{x}}{m}$, hence the fluxion of the logarithm of any quantity in any system of logarithms is equal to the fluxion of that quantity multiplied by the modulus of the system, and divided by the quantity itself.

(27.) By means of logarithms the fluxions of exponential quantities

ties are found, as of y^x which put equal to z , then by the properties of logarithms the $\log. z = x \times \log. y$, hence by taking the

$$\text{fluxions } \frac{\dot{z}}{z} = x \times \log. y + x \times \frac{\dot{y}}{y} \quad (\text{art. 25, and 19,}) \text{ therefore } \dot{z} = z \times \log. y + \frac{z x \dot{y}}{y} = (\text{by puling } y^x \text{ for its equal } z) y^x \dot{x} \times \frac{z}{y}$$

$\log. y + x y^{x-1} \dot{y}$ = the fluxion of the exponential y^x ; which consists of two terms, and it is evident that if either of the quantities x or y be constant, the term into which its fluxion enters will vanish, the fluxion being equal to nothing: hence when the root y is constant, the fluxion of the exponential quantity y^x is equal $\dot{y}^x \times \log. y$. If x be constant it ceases to be an exponential, and the fluxion is $x y^{x-1} \dot{y}$ as in articles 22, 23, and 24.

(28.) The second fluxion is derived from the first, and the third from the second &c. in the same manner as the first from the flowing quantity. Thus the fluxion of x^3 is $3 x^2 \dot{x}$; (art. 22,) its second fluxion is $6 x \ddot{x} + 3 x^2 \ddot{x}$, (art. 19, and 22,) &c. If $\ddot{x}$ be constant, $\ddot{x} = 0$, and the second fluxion of x^3 is $6 x \ddot{x}$.

(29.) In the foregoing articles, it has been supposed that the fluents increase, and that their fluxions are therefore positive; but when it happens that the fluents decrease, then the fluxions are negative and must be written with a contrary sign to that determined by those articles; thus if in the product $x y$, y decrease while x increases, the fluxion of y is $-\dot{y}$ and the fluxion of the product is $y \dot{x} - x \dot{y}$.

(30.) From what has been advanced we may easily collect the following practical rules for finding the fluxions of quantities.

1st. *For the fluxion of any power or root of a flowing quantity.* Multiply by the index and by the fluxion of the root, and diminish the index by unity, (art. 22, 23, 24.)

2nd. *For the fluxion of a product.* Multiply the fluxion of each quantity by the product of all the rest, and connect them by their proper signs, (art. 19, 20.)

3rd. *For the fluxion of a fraction.* From the fluxion of the numerator multiplied into the denominator, subtract the fluxion of the denominator multiplied into the numerator, and divide by the square of the denominator, (art. 21.)

4th. *For the fluxion of a logarithm.* Divide the fluxion of the quantity by the quantity itself, and multiply the result into the modulus of the system of logarithms, (art. 25, 26.)

5th. *For the fluxion of an exponential quantity.* Multiply the given quantity into the fluxion of its exponent and into the hyp. log. of the root, and add the fluxion of the given quantity, found by the first rule, as if the root only were variable. The last part vanishes, and therefore need not be found when the root is constant, (art. 27.)

6th. In complex cases the preceding rules are to be used jointly. Or the following general rule will be found useful when there are several variable quantities. Take the fluxion of the given quantity as often as there are variable letters or symbols in it, supposing first only one of them variable, and the rest constant; then another variable, and the rest constant; and so on till each has been considered as variable, and connect all these fluxions by their proper signs.

Note. When the given quantity consists of several terms, find the fluxion of each term separately, and connect them all together by their proper signs. The following example is added to illustrate the rules, particularly the sixth.

Examp. To find the fluxion of $\frac{2 a x^3 y^3}{z} + \text{hyp. log. } x z - c y z^x$, where x, y and z are flowing quantities. Proceeding as directed in the first part of rule 6, the fluxion will stand thus;

$$\frac{4 a x^3 y \dot{y} + 6 a y^3 x^2 \dot{x} \times z - 2 a x^3 y^3 \dot{z}}{z^2} + \frac{x \dot{z} + z \dot{x}}{x z} - c z^x \dot{y} -$$

$(z^x \times \text{hyp. log. } z + x z^{x-1} \dot{z}) \times c y$. Or, proceeding according to the latter part of the 6th rule it will stand as follows, viz.

$$\frac{4 a x^3 y \dot{y}}{z^2} + \frac{6 a y^3 x^2 \dot{x}}{z} + \frac{2 a x^3 y^3 \dot{z}}{z^2} + \frac{\dot{z}}{z} + \frac{\dot{x}}{x} - c z^x \dot{y} - c y z^x \dot{z}$$

$\times \text{hyp. log. } z - c x y z^{x-1} \dot{z}$, which is the same as the foregoing. The second, third, &c. fluxions are found by the same rules (art. 28.)

Thus the fluxion of x^3 is $3 x^2 \dot{x}$; its second, $6 x \ddot{x} + 3 x^2 \ddot{x}$; and so on: but if $\ddot{x}$ be invariable, $\ddot{x} = 0$, and the second fluxion of $x^3 = 6 x \ddot{x}$.

PROB. I. TO DETERMINE MAXIMA and MINIMA.

(31.) When a quantity increases, its fluxion is positive; when it decreases, it is negative; therefore when it is just betwixt increasing and decreasing, its fluxion is $= 0$.

Rule. Find the fluxion, make it $= 0$, whence an equation will result giving an answer to the question.

(32.) *Examp. 1.* To determine the dimensions of a cylindric measure ABCD, fig. 9, open at the top, which shall contain a given quantity under the least internal superficies possible.

Let the diameter AB $= x$, the altitude AC $= y$, the given quantity, or content $= c$, and $\frac{1}{4}$ of the circumference of a circle whose diameter is unity $= p = .78539$, &c. Then $p x^2 y = c$, and

$$4 p x y = \frac{4 c}{x}, \text{ but } 4 p x y = \text{the concave superficies, therefore}$$

$$\frac{4 c}{x} + p x^2 = \text{the whole internal superficies, which is to be a mi-}$$

$$\text{nimum, therefore, its fluxion } - \frac{4 c \dot{x}}{x^2} + 2 p x \dot{x} = 0, \text{ hence } p x^3$$

$$= 2 c, \text{ and } x = \sqrt[3]{\frac{2 c}{p}}. \text{ Since } p x^3 = 2 c, \text{ and } p x^2 y = c, p x^2 y$$

$$= 2 p x^2 y, \text{ and } x = 2 y; \text{ whence } y \text{ is also known, and the dia-}$$

meter of the base must be just double the altitude.

Examp. 2. Let ABC represent a cone, AC the diameter of the base; to inscribe in it the greatest cylinder DFGI, fig. 16.

Put $p = .78539$, &c., then since AC $= a$. BH $= b$. BE

$$= x, \frac{p a^2 x^2}{b^2} = \text{the area of the end D E F of the cylinder; hence,}$$

$$\text{the content of the cylinder} = \frac{p a^2 x^2}{b^2} \times \overline{b-x} = \text{max. or } x^2 \times$$

$$\overline{b-x} = b x^2 - x^3 = \text{max. } \therefore 2 b x \dot{x} - 3 x^2 \dot{x} = 0; \text{ hence, } x =$$

$$\frac{2}{3} b; \text{ therefore } E H = \frac{1}{3} b.$$

Examp. 3. Given $x + y + z = a$, and $x y^2 z^3$ a maximum, to find x, y , and z .

As x, y, z , must have some certain determinate values to answer these conditions, let us suppose such a value of y to remain constant, whilst x and z vary till they answer the conditions, and then $\dot{x} + \dot{z} = 0$, and $z^3 \dot{x} + 3 x z^2 \dot{z} = 0$; hence, $\dot{x} = -\dot{z} = -$

$$\frac{3 x z^2 \dot{z}}{z^3} = -\frac{\dot{z}}{z}, \therefore z = 3 x. \text{ Now let us suppose the value of}$$

z to remain constant, and x and y to vary, so as to satisfy the conditions; then $\dot{x} + \dot{y} = 0$, $y^2 \dot{x} + 2 x y \dot{y} = 0$; hence, $\dot{x} = -\dot{y} = -$

$$\frac{2 x y \dot{y}}{y^2} = -\frac{\dot{y}}{y}, \therefore y = 2 x; \text{ substitute in the given equa-}$$

$$\text{tion these values of } y \text{ and } z \text{ in terms of } x, \text{ and } x + 2x + 3x = a, \text{ or}$$

$$6 x = a; \text{ hence, } x = \frac{1}{6} a; \therefore y = \frac{1}{3} a; z = \frac{1}{2} a. \text{ In like man-}$$

ner, whatever be the number of unknown quantities, make any one of them variable with each of the rest, and the values of each in terms of that one quantity will be obtained; and by substituting the values of each in terms of that one, in the given equation, you will get the value of that quantity, and hence the values of the others.

(33.) Fig. 10. To find the longest and shortest ordinates of any curve, DEF, whose equation is known.

Make AC the abscissa = x , and CE the ordinate = y ; take by means of the equation of the curve a value of y in terms of x , and find its fluxion; which making = 0, an equation will result whose roots give the value of x when y is a maximum or minimum.

(34.) To determine when it is a maximum and when a minimum, take the value of y , when x is a little more than the root of the equation so found, and it may be perceived whether it increases or decreases.

PROB. II. TO DRAW A TANGENT TO ANY CURVE.

(35.) If TQ q be a tangent at Q to the curve AB, fig. 5, and 6, and P p or Q r the fluxion of the absciss, then $r q$ is the fluxion of the ordinate P Q, and since the triangles Q $r q$ and TPQ are similar, $r q : r Q :: Q P : P T$; hence we have this

Rule. As the fluxion of the ordinate in terms of the absciss, is to the fluxion of the absciss, so is the ordinate, to the subtangent PT, and from T thus found, and through Q, the tangent is to be drawn.

Examp. To draw a right line CT, fig. 11, to touch a given circle BCA in a point C.

Let CS be perpendicular to the diameter AB, and put AO = OB = a , BS = x , and SC = y : then, by the property of the

$$\text{circle, } y = \sqrt{2ax - x^2}, \text{ and } \dot{y} = \frac{a\dot{x} - x\dot{x}}{\sqrt{2ax - x^2}} : \dot{x} :: \sqrt{2ax - x^2}$$

$2ax - x^2$
: $\frac{a - x}{\sqrt{2ax - x^2}}$ = ST, the subtangent; which we also know from other principles.

PROB. III. TO DETERMINE POINTS OF CONTRARY FLEXURE IN CURVES.

(36.) Fig. 10. Supposing CE to move uniformly from A to B, the curve DEF will be convex towards AB when the fluxion of the ordinate increases, and concave when it decreases (art. 16.); therefore at the point where it ceases to be convex and begins to be concave, CE will have no second fluxion. And from this it is evident, that if we suppose the ordinate CE to increase uniformly, or its fluxion to be constant, the curve will be convex while the fluxion of the absciss decreases, and concave while it increases; hence, in the point of inflexion, the second fluxion of the absciss will vanish; therefore, we have this

Rule. Find the second fluxion of either the ordinate or absciss, supposing the fluxion of the other constant, and put it = 0, then from this equation, and the equation of the curve, the value of the absciss is determined.

Examp. 1. Let the nature of the curve be defined by the equation, $a x^2 = a^2 y + x^2 y$, then $y = \frac{a x^2}{a^2 + x^2}$, and $\dot{y} = 2 a \dot{x} \times$

$$\frac{x}{(a^2 + x^2)^2} : \text{hence, since } \dot{x} \text{ is constant, } \dot{y} = 2 a \dot{x} \times \frac{a^2 - 3x^2}{(a^2 + x^2)^3} = 0; \text{ therefore } 3x^2 = a^2, \text{ and } x = a \sqrt{\frac{1}{3}} = AF; \text{ from which we}$$

$$\text{determine FG or } y = \frac{a x^2}{a^2 + x^2} = \frac{\frac{1}{3} a^3}{a^2 + \frac{1}{3} a^2} = \frac{1}{4} a.$$

Examp. 2. To find the point of inflexion or contrary flexure in the conchoid of Nicomedes, fig. 12, putting AB = x , and BC = y , also AG = b , and AP = a , then the equation of the curve

$$\text{is } x = \frac{a+y}{y} \times \sqrt{b^2 - y^2}; \text{ hence } \dot{x} = \dot{y} \times \left(-\frac{a}{y^2} \times \sqrt{b^2 - y^2} - \frac{a+y}{y^2} \right), \text{ and considering } \dot{y} \text{ constant, } \dot{x} = y^3 \dot{y}^2 \sqrt{b^2 - y^2} \times$$

$$\left(2a \times \frac{b^2 - y^2}{b^2 - y^2} + a y^2 - y^3 - \frac{a y^4 + y^5}{(b^2 - y^2)} \right) = 0, \text{ or } y^3 + 3a y^2 =$$

$$2ab^2, \text{ from which } y \text{ and } x \text{ are easily found. If } \dot{x} \text{ had been considered constant, we should have had } \dot{y} = -\dot{x} \times \frac{y^2 \sqrt{b^2 - y^2}}{ab^2 + y^3}$$

$$\text{hence } \dot{y} = -\frac{\dot{x} y \sqrt{b^2 - y^2}}{(ab^2 + y^3)^2} \times \frac{(2b^2 - 3y^2) \times ab^2 + y^3 - 3b^2 y^4 + 3y^5}{(ab^2 + y^3)^2} = 0, \text{ from which } y^3 + 3a y^2 = 2ab^2 \text{ as before.}$$

PROB. IV. TO FIND THE RADII OF CURVATURE.

(37.) The curvature of a circle is uniform in every point, that of every other curve continually varying: and it is measured at any point by that of a circle whose radius is of such a length that the circle shall coincide with it in curvature in that point.

Thus if the circle SQD, and curve AQB, (fig. 13,) have the same curvature at the point Q, and CQ be the radius of the circle, it will also be the radius of curvature of the curve at Q, and if the curve be generated by the evolution of a line from the curve ICE, so that the radius of curvature CQ is always equal to the part CIA, then is the curve ICE called the evolute, of which the curve AQB is the involute.

Draw the diameter SD parallel to the absciss AP, draw the ordinate QPF, and the tangent TQ q , also draw Q r parallel to AP or SF, and $r q$ parallel to QP, and put AP = x , PQ = y , and QC = r , = radius of curvature. Now, since the curves SQD, AQB, have the same curvature at Q, they have a common tangent TQ q , at right angles to QC; hence they have the same fluxion $\dot{x}$ measured by Q q , also the fluxions of their abscisses and ordinates are the same; that is $\dot{x}$ and $\dot{y}$ measured by Q r , and $r q$ are also the fluxions of SF and FQ, but from the similar

$$\text{triangles Q } r q \text{ and QCF, } QF = \frac{r \dot{x}}{\dot{z}}, \text{ and } FC = \frac{r \dot{y}}{\dot{z}}, \text{ or}$$

$$SF = r - \frac{r \dot{y}}{\dot{z}}; \text{ therefore taking the fluxions, } r \dot{\dot{x}} - r \dot{\dot{z}} =$$

$$\dot{z}^2 \dot{y}, \text{ and } -r \dot{\dot{y}} \dot{z} + r \dot{y} \dot{\dot{z}} = \dot{z}^2 \dot{x}, \text{ hence } \dot{\dot{z}} = \frac{r \dot{\dot{x}} - \dot{z}^2 \dot{y}}{\dot{z}^2} = \frac{r \dot{\dot{x}} + \dot{z}^2 \dot{x}}{\dot{z}^2},$$

$$\text{or, } r \dot{\dot{x}} - \dot{z}^2 \dot{y} = r \dot{y} \dot{\dot{z}} + \dot{z}^2 \dot{x}, \text{ or, } QC = r = \frac{\dot{z}^2 + \dot{y}^2 \times \dot{z}}{\dot{x} \dot{y} - \dot{y} \dot{x}}$$

Any of the quantities $\dot{x}$, $\dot{y}$, or $\dot{z}$ may be supposed

constant, if $\dot{x}$ be constant, or $\dot{x} = 0$, it will become $\frac{\dot{z}^2}{-\dot{x} \dot{y}}$, if $\dot{y}$

be constant, or $\dot{y} = 0$, it will be $\frac{\dot{z}^2}{\dot{y} \dot{x}}$, and if $\dot{z}$ be constant it will

be $\frac{\dot{z} \dot{y}}{\dot{x}}$ = QC, for $\dot{x}^2 + \dot{y}^2 = \dot{z}^2$, and by taking the fluxions

$$2\dot{x} \dot{\dot{x}} + 2\dot{y} \dot{\dot{y}} = 0, \text{ or, } \dot{\dot{y}} = -\frac{\dot{x} \dot{\dot{x}}}{\dot{y}}, \text{ and } QC = \frac{\dot{z}^2}{\dot{y} \dot{x} - \dot{y} \dot{x}} =$$

$$\frac{\dot{z}^2}{\dot{y} \dot{x} + \frac{\dot{x} \dot{\dot{x}}}{\dot{y}} \times \dot{z}} = \frac{\dot{y} \dot{z}^2}{\dot{y}^2 + \dot{x}^2 \times \dot{z}} = \frac{\dot{y} \dot{z}^2}{\dot{z}^2} = \dot{y}$$

From these several values of the radius of curvature QC, here found, the corresponding values of AK and KC, will be obtained, by means of the equations above.

$$\text{Thus AK} = AP + FC = x + \frac{r \dot{y}}{\dot{z}} = x + \frac{\dot{z}^2 \dot{y}}{\dot{y} \dot{x} - \dot{y} \dot{x}}, \text{ and KC}$$

$$= QF - QP = \frac{r \dot{x}}{\dot{z}} - y = \frac{\dot{z}^2 \dot{x}}{\dot{y} \dot{x} - \dot{y} \dot{x}} - y. \text{ Hence if } \dot{x} \text{ be con-}$$

$$\text{stant, AK} = x + \frac{\dot{z}^2 \dot{y}}{-\dot{x} \dot{y}}, \text{ and KC} = \frac{\dot{z}^2}{-\dot{y}} - y. \text{ If } \dot{y} \text{ be constant,}$$

$$AK = x + \frac{\dot{z}^2}{\dot{y} \dot{x}}, \text{ and KC} = \frac{\dot{z}^2}{\dot{y} \dot{x}} - y. \text{ Lastly, if } \dot{z} \text{ be constant,}$$

then, r being $\frac{\dot{y}z}{x}$, $AK = x + \frac{\dot{y}z}{x}$, and $KC = \frac{\dot{y}z}{x} - y$.

And these expressions will serve as so many theorems for determining the curvature, and the evolutes of given curves.

Examp. To find the radius of curvature, and the evolute of the common cycloid.

Let AQB, (fig. 14.) be the given curve, and ACH its evolute, and let QD and EC be parallel, and QF and KC perpendicular to AG; put $AQB = a (= 2BG)$, $AQ = z$, $AP = x$, and $QP = y$. And by the property of the curve $AB^2 : BQ^2 :: BG : BD$, or

$$y = \frac{2az - z^2}{2a}; \text{ therefore } \dot{y} = \frac{a - z}{a}, \quad \dot{z}^2 - \dot{y}^2 = \dot{x}^2 =$$

$$\frac{2az - z^2 \times \dot{z}^2}{a^2}, \text{ and } \dot{x} = \frac{\dot{z}\sqrt{2az - z^2}}{a}. \text{ And making } \dot{z} \text{ constant}$$

$$\dot{x} = \frac{\dot{z}^2 \times \overline{a - z}}{a\sqrt{2az - z^2}}; \text{ hence } QC = \frac{\dot{y}z}{\dot{x}} = \sqrt{2az - z^2}, \text{ and } KC$$

$$\text{or } AE = \frac{\dot{y}z}{\dot{x}} - y = \frac{2az - z^2}{2a}, \text{ which when } z = a, \text{ or } QCH$$

coincides with BH, $ACH = BH = a$, and hence $GH = \frac{1}{2}a$, therefore because $AH^2 (a^2) : AC^2 (2az - z^2) :: AO (\frac{1}{2}a) : AE (\frac{2az - z^2}{2a})$ which is the property of the cycloid, the evolute ACH is also a cycloid, equal and similar to the involute AQB.

PROB. V. TO DEMONSTRATE THE BINOMIAL THEOREM.

(38.) It is well known, that by the continual multiplication of $1 + x$, a series is produced with all the powers of x regularly ascending; the first term being 1, and that the coefficients are not affected by the value of x , so that if x be made to vanish, they are unaltered: let $(1 + x)^n = 1 + ax + bx^2 + cx^3 + dx^4 + \&c.$ Now, to determine the values of $a, b, c, d, \&c.$ take the fluxion of both sides of this equation, omitting x , which is found in every term; then take the fluxion of the resulting equation, and so on continually, whence the following equations:

$$n \times (1 + x)^{n-1} = a + 2bx + 3cx^2 + 4dx^3 + \&c.$$

$$n \times n-1 \times (1 + x)^{n-2} = 2b + 2.3cx + 3.4dx^2 + \&c.$$

$$n \times n-1 \times n-2 \times (1 + x)^{n-3} = 2.3c + 2.3.4dx + \&c.$$

Now make $x = 0$, and from the first equation, $n = a$; from the second, $n.n-1 = 2b$; from the third $\frac{n.n-1.n-2}{n-1} = 2.3c$, &c, hence $a = n$; $b = n \cdot \frac{n-1}{2}$, $c = n \cdot \frac{n-1}{2} \cdot \frac{n-2}{3}$, &c.

$$\text{Hence } (1 + x)^n = 1 + nx + n \cdot \frac{n-1}{2} x^2 + n \cdot \frac{n-1}{2} \cdot \frac{n-2}{3} x^3 + \&c.$$

$x^3 + \&c.$ which investigation holds whether n be a whole number or fraction, positive or negative. It is evident, that if x be negative, the odd powers in the series will be negative. See ALGEBRA.

THE INVERSE METHOD, OR THE FINDING OF FLUENTS.

(39.) The fluxion of any flowing quantity may be easily found in all cases; but it is difficult to find the fluents of many given fluxions, and frequently it cannot be done at all, except by means of the quadrature or rectification of curve lines, or by logarithms or by infinite series; for, as there is no method for deducing the fluent from the fluxion a priori, by a direct investigation; therefore we can only lay down rules for those particular forms of fluxions

that we know, from the direct method, belonging to such kinds of flowing quantities.

1. To find the fluent of any simple fluxion, you need only write the letters without the dots over them: thus, the fluent of $\dot{x}$ is x , and that of $a\dot{x} + b\dot{y}$, is $ax + by$.

2. To assign the fluent of any power of a variable quantity, multiplied by the fluxion of the root; first divide by the fluxion of the root, add unity to the exponent of the power, and divide by the exponent so increased: for dividing the fluxion $n\dot{x}^{n-1}$ by $\dot{x}$ it becomes $n\dot{x}^{n-1}$; and adding 1 to the exponent $(n-1)$ we have $n\dot{x}^n$; which, divided by n , gives $\dot{x}^n$, the fluent of $n\dot{x}^{n-1}$. Hence, by the same rule, the fluent of $2x^5\dot{x}$ is $\frac{2}{6}x^6$; that of $\frac{a+z}{4}\dot{z}$ is $\frac{a+z}{4}$; and that of $a^m + z^m$ is $\frac{a^m + z^m}{m+1}$.

When the root under a vinculum is a compound quantity, and the index of the part or factor without the vinculum, increased by 1, is some multiple of that under the vinculum, put a single variable letter for the compound root, and substitute its powers and fluxion instead of those of the same value, in the given quantity, so will it be reduced to a more simple form, to which the preceding rule can then be applied. Let $a^2 + x^2$ be proposed, put $z = a^2 + x^2$, then $\dot{z} = 2x\dot{x}$, and

hence $x^2\dot{x} = \frac{1}{2}\dot{z}$, and $(a^2 + x^2)^{\frac{3}{2}}x^2\dot{x} = \frac{1}{2}\dot{z}^{\frac{3}{2}}$, its fluent is $\frac{1}{2} \cdot \frac{2}{5} \dot{z}^{\frac{5}{2}} = \frac{1}{5} \dot{z}^{\frac{5}{2}}$, and by substituting the value of z , the fluent becomes $\frac{1}{5} (a^2 + x^2)^{\frac{5}{2}}$.

3. To find the fluents of such fluxionary expressions as involve two or more variable quantities, substitute, instead of such fluxion, its respective flowing quantity; and if every term be the same quantity, that quantity will be the fluent. If the terms differ in the signs, it shews that some of the factors increase while others decrease. Thus the fluent of $\dot{x}y + \dot{y}x$, or $\dot{x}y - \dot{y}x = xy$; in the latter case y decreases while x increases, and the fluent of $\dot{x}y - \dot{y}x$ is $xy - yx$, also the fluent of $\frac{\dot{x}y}{y^2}$, or

$\frac{\dot{x}y}{y^2} = \frac{\dot{x}}{y}$, where x increases, while $\frac{1}{y}$ decreases, and $\frac{\dot{y}x}{y^2} = \frac{\dot{y}}{y^2}x$, where both factors x and $\frac{1}{y^2}$ increase or decrease together. But it seldom happens that these kinds of fluxions, which involve two variable quantities in one term, and yet admit of known and perfect fluents, are to met with in practice.

4. When the fluxion of a quantity is divided by the quantity itself, the fluent is the hyperbolic logarithm of that quantity, or which is the same, the common logarithm multiplied into 2.30258,

&c. Thus the fluent of $\frac{\dot{x}}{x}$ is the hyperbolic logarithm of x ,

and the fluent of $\frac{a\dot{x}}{x}$ is $a \times$ hyperbolic logarithm of x . On the same principle the fluents of the four following fluxionary forms are obtained:

First Form. The fluent of $\frac{2ab\dot{x}}{a^2 - x^2}$, or $b \times \frac{2a\dot{x}}{a^2 - x^2}$, is $b \times$ hyperbolic logarithm of $\frac{a+x}{a-x}$; for the fluxion of $\frac{a+x}{a-x} = \frac{2a\dot{x}}{a-x^2}$, which divided by $\frac{2a\dot{x}}{a-x^2}$, gives $\frac{a+x}{a-x}$. The truth of the other forms are shewn in the same manner.

Second

Second Form. The fluent of $\frac{b \dot{x}}{\sqrt{x^2 \pm a^2}}$ is $b \times$ hyperbolic logarithm of $x + \sqrt{x^2 \pm a^2}$.

Third Form. The fluent of $\frac{b \dot{x}}{\sqrt{2ax + x^2}}$ is $b \times$ hyperbolic logarithm of $a + x + \sqrt{2ax + x^2}$.

Fourth Form. The fluent of $\frac{2ab\dot{x}}{x\sqrt{a^2 \pm x^2}}$ is $b \times$ hyperbolic logarithm of $\frac{a - \sqrt{a^2 \pm x^2}}{a + \sqrt{a^2 \pm x^2}}$.

5. Certain fluents may be found by means of circular arcs of a circle to the radius 1.

Let AD, fig. 13, be a circular arc, put AT, its tangent = t , DB the sine = y , AB = x , CT = s , the radius CD = a , and the arc AD = z ; also let the tangent Ds represent $\dot{z}$, Dn parallel to AB, sn to DB will express $\dot{x}$ and $\dot{y}$. Then from the similar triangles TAC, DBC, and Dns, we obtain $\dot{z} = \frac{a^2 \dot{t}}{a^2 + t^2} = \frac{a \dot{y}}{\sqrt{a^2 - y^2}}$

$= \frac{a \dot{x}}{\sqrt{2ax - x^2}} = \frac{a^2 \dot{s}}{s\sqrt{s^2 - a^2}}$, and thus four forms of fluxions,

which differ only in the signs from those found by logarithms, may be found by means of circular arcs, whose lengths are given in a table, to a circle, the radius of which is 1, thus,

First Form. The fluent of $\frac{b a \dot{t}}{a^2 + t^2} = b \times$ arc to tang. $\frac{t}{a}$.

Second Form. The fluent of $\frac{b \dot{y}}{\sqrt{a^2 - y^2}} = b \times$ arc to sine $\frac{y}{a}$.

Third Form. The fluent of $\frac{b \dot{x}}{\sqrt{2ax - x^2}} = b \times$ arc to vers. $\frac{x}{a}$.

Fourth Form. The fluent of $\frac{b a \dot{s}}{s\sqrt{s^2 - a^2}} = b \times$ arc to sec. $\frac{s}{a}$.

To the above we add the following, which are easily investigated; the hyperbolic logarithm is to be understood, and the radius of the circle is 1.

FORMS.	FLUXIONS.	FLUENTS.
I.	$\frac{x^{2n-1} \dot{x}}{a \pm x^n}$	$\pm \frac{1}{n}$ logarithm of $a \pm x^n$
II.	$\frac{x^{-1} \dot{x}}{a \pm x^n}$	$\frac{1}{na}$ logarithm of $\frac{x^n}{a \pm x^n}$
III.	$\frac{x^{\frac{1}{2}n-1} \dot{x}}{a - x^n}$	$\frac{1}{n\sqrt{a}}$ logarithm of $\frac{\sqrt{a} + \sqrt{x^n}}{\sqrt{a} - \sqrt{x^n}}$
IV.	$\frac{x^{\frac{1}{2}n-1} \dot{x}}{a + x^n}$	$\frac{1}{n\sqrt{a}}$ $\times$ arc to cosine $\frac{a - x^n}{a + x^n}$

FORMS.	FLUXIONS.	FLUENTS.
V.	$\frac{x^{\frac{1}{2}n-1} \dot{x}}{\sqrt{\pm a + x^n}}$	$\frac{2}{n}$ logarithm of $\sqrt{x^n} + \sqrt{\pm a + x^n}$
VI.	$\frac{x^{\frac{1}{2}n-1} \dot{x}}{\sqrt{a - x^n}}$	$\frac{2}{n} \times$ arc to sine $\sqrt{\frac{x^n}{a}}$
VII.	$\dot{x}\sqrt{2ax - x^2}$	$\frac{1}{2}$ circ. seg. to rad. a and vers. x

(40.) When the given fluxion is so complex that its fluent cannot be found by any of these means, it is then to be determined by the method of infinite series; thus, expand the radical or fraction in the given fluxion by division, extraction of roots, the binomial theorem, &c. and multiply the series by the fluxional letter, if it had been left out in the operation, and such variable simple factor as the given fluxional expression may contain; then find the fluent of each term, by the foregoing rules for the fluents required.

Thus, if it were proposed to find the fluent of $\frac{a\dot{x}}{a-x}$, it becomes necessary to throw the fluxion into an infinite series, by dividing $a\dot{x}$ by $a-x$: thus, $a\dot{x} \div a-x = \dot{x} + \frac{x\dot{x}}{a} + \frac{x^2\dot{x}}{a^2} + \frac{x^3\dot{x}}{a^3} + \frac{x^4\dot{x}}{a^4} + \dots$ Now the fluent of each term of this series, may be found by the foregoing rules to be $x + \frac{x^2}{2a} + \frac{x^3}{3a^2} + \frac{x^4}{4a^3} + \frac{x^5}{5a^4} + \dots$ Again, to approximate the fluent of $\frac{a^2 - x^2}{a^2 - x^2} \times \frac{1}{2} x^n$, we first find the value of $\frac{a^2 - x^2}{a^2 - x^2} \times \frac{1}{2}$ expressed in a series to be

$\frac{a}{c} + \frac{a}{2c^3} - \frac{1}{2ac} \times x^2 + \frac{3a}{8c^5} - \frac{1}{4ac^3} - \frac{1}{8a^3c} \times x^4 + \frac{5a}{16c^7} - \frac{3}{16ac^5} - \frac{1}{16a^3c^3} - \frac{1}{16a^5c} \times x^6 + \dots$ which value

being multiplied by x^n , and the fluent taken by the rules above

laid down, we get $\frac{ax^{n+1}}{n+1 \times c} + \frac{a}{2c^3} - \frac{1}{2ac} \times \frac{x^{n+3}}{n+3} + \frac{3a}{8c^5} - \frac{1}{4ac^3} - \frac{1}{8a^3c} \times \frac{x^{n+5}}{n+5} + \frac{5a}{16c^7} - \frac{3}{16ac^5} - \frac{1}{16a^3c^3} - \frac{1}{16a^5c} \times \frac{x^{n+7}}{n+7} + \dots$

(41.) The fluent found from a given fluxion by the foregoing rules will frequently require a correction, for though a fluent can have but one fluxion, yet a fluxion may have an infinite number of

of fluents; thus the fluent of $\dot{x}$ is x , or $x \pm c$, (art. 18.) whatever be the value of the constant part c , called the correction.

To determine the correction, consider whether the fluent becomes equal to nothing, or of a known value at the time it ought; if not such a quantity must be annexed as will bring it to its proper value. Or proceed by the following rule:

In the general equation of the fluents, write for each quantity the value it is known to have at any one certain time or position, and subtract the sides of the resulting equation from the corresponding side of the general one, and the remainder will give the correction sought.

Let $\dot{z} = 4ax^3$, the general fluent is $z = ax^4$, and let $z = d$ when $x = b$; then,

For the general equation $z = ax^4$; substitute d for z , and b for x , then $d = ab^4$, and by subtracting $z = d = ax^4 - ab^4$, or $z = ax^4 - ab^4 + d$ the correct fluent, the correction being equal to $d - ab^4 = c$, it is evident that if $d = 0$, the correction is $c = -ab^4$, and if $b = 0$, it is $c = d$, if $d = 0$, and $b = 0$, the correction vanishes, or is equal to nothing.

PROB. I. TO FIND THE AREA OF ANY CURVE.

(42.) RULE. Multiply the ordinate by the fluxion of the absciss, and the product gives the fluxion of the figure, whose fluent, corrected if necessary, is the area of the figure.

Examp. 1. Fig. 17. Let the curve ARMH be the common parabola. Let u represent the area, and $\dot{u}$ its fluxion.

$y = a^{\frac{1}{2}} x^{\frac{1}{2}}$; therefore $\dot{u} = Rm HB (= y\dot{x}) = a^{\frac{1}{2}} x^{\frac{1}{2}} \dot{x}$: whence $u = \frac{2}{3} \times a^{\frac{1}{2}} x^{\frac{3}{2}} = \frac{2}{3} a^{\frac{1}{2}} x^{\frac{1}{2}} \times x = \frac{2}{3} yx = \frac{2}{3} \times AB \times BR$: hence a parabola is $\frac{2}{3}$ of a rectangle of the same base and altitude.

Examp. 2. Let the proposed curve CSDR (fig. 18.) be of such a nature, that (supposing AB unity) the sum of the areas CSTBC and CDGBC, whose abscisses are AT and AG, shall be equal to the area CRNBC, whose corresponding absciss AN is equal to AT $\times$ AG, the product of the measures of the two former abscisses.

First, in order to determine the equation of the curve (which must be known before the area can be found,) let the ordinates GD and NR move parallel to themselves towards HF; and then having put $GD = y$, $NR = z$, $AT = a$, $AG = s$, and $AN = u$, the fluxion of the area CDGB will be represented by $y\dot{s}$, and that of the area CRNB by $z\dot{u}$: which two expressions must, by the nature of the problem, be equal to each other; because the latter area CSTB, which is here considered as a constant quantity: and it is evident that two expressions that differ only by a constant quantity, must always have equal fluxions.

Since, therefore, $y\dot{s} = z\dot{u}$, and $u = as$, by hypothesis, it follows, that $\dot{u} = a\dot{s}$, and that the first equation (by substituting for $\dot{u}$) will become $y\dot{s} = az\dot{s}$, or $y = az$, or lastly $y\dot{s} = zas$, that is, $GD \times AG = NR \times AN$: therefore, $GD:NR::AN:AG$; whence it appears, that every ordinate of the curve is reciprocally as its corresponding absciss.

Now, to find the area of the curve so determined, put $AB = 1$, $BC = b$, and $BG = x$: then since $AG (1+x):AB (1):BC$

$(b):GD (y)$ we have $y = \frac{b}{1+x}$, consequently $\dot{u} (=y\dot{x}) =$

$\frac{b\dot{x}}{1+x} = b \times \dot{x} \times \frac{1-x}{1+x} = \frac{b}{1+x} (1-x) \dot{x}$, &c. Whence BGDC,

the area itself, will be $= b \times x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \frac{x^5}{5}$, &c.

which was to be found.

(43.) Hence it appears, that as these areas have the same properties as logarithms, this series gives an easy method of computing logarithms; and the fluent may be found by means of a table of logarithms; and every fluxion whose fluent agrees with any known logarithmic expression, may be found the same way.

PROB. II. TO DETERMINE THE LENGTH OF CURVES.

(44.) Fig. 19. Because Ced is a right-angle, $Cd^2 = Ce^2 + de^2$; wherefore the fluxions of the absciss and ordinate being

squared, their sum gives the square of the fluxion of the curve; whose root being extracted, and the fluent taken, gives the length of the curve.

Examp. To find the length of a circle from its tangent. Make the radius AO , fig. 19, $= a$, the tangent of $AC = t$, and its secant $= s$, the curve $= z$, and its fluxion $\dot{z}$; because the triangles OTC , OCS , are similar, $OT:OC::OC:OS$; whence $OS =$

$\frac{a^2}{s}$, and $SA = a - \frac{a^2}{s} = a - \frac{a^2}{\sqrt{a^2+t^2}}$; whose fluxion is $\frac{a^2 t \dot{t}}{a^2+t^2}$

and because the triangles OTC , dCe are similar, $TC (=t):TO (=$

$\sqrt{a^2+t^2})::Cd (= \frac{a^2 t \dot{t}}{a^2+t^2}):C\dot{d} = \frac{a^2 \dot{t}}{a^2+t^2}$ = fluxion of

the curve. Now by converting this into an infinite series we have

the fluxion of the curve $= \frac{t^2 \dot{t}}{a^2} + \frac{t^4 \dot{t}}{a^4} + \frac{t^6 \dot{t}}{a^6}$, &c. and conse-

quently $z = t - \frac{t^3}{3a^2} + \frac{t^5}{5a^4} - \frac{t^7}{7a^6} + \frac{t^9}{9a^8}$, &c. = AR.

(45.) Other series may be deduced from the versed sine, secant, &c. and these are of use for finding fluents which cannot be expressed in finite terms.

PROB. III. TO FIND THE CONTENT OF A SOLID.

(46.) Let the surface of the generating plane be multiplied by the space it passes through in any time, the product will give a solid which is the fluxion of the solid required: the surface must be computed in terms of x , which represents the line or axis on which it moves, and by its motion on which the fluxion is to be measured, and the fluent found will give the content of the solid.

Examp. 1. Let it be proposed to find the content of a cone ABC, fig. 20.

Put the given altitude (AD) of the cone $= a$, and the semidiameter (BD) of its base $= b$, the solid $= s$, its fluxion $= \dot{s}$ and the area of a circle, whose radius is unity, $= p$: then the distance (AF) of the circle EH, from the vertex A, being denoted by x , we have by similar triangles, as $a:b::x:EF (y) = \frac{bx}{a}$.

Whence in this case, $\dot{s} (= p y^2 \dot{x}) = \frac{p b^2 x^2 \dot{x}}{a^2}$; and consequently $s =$

$\frac{p b^2 x^3}{3a^2}$; ($= p \times BD^2 \times \frac{1}{3} AD$) for the content of the whole

cone ABC: which appears from hence to be just $\frac{1}{3}$ of a cylinder of the same base and altitude.

Examp. 2. Let it be required to find the solid content of a spheroid, AFBH, fig. 21. Let the axis AB, about which the solid is generated, be $= a$, p = area of a circle to the radius 1, and the other axis FH of the generating ellipsis $= b$; then, from the property of the ellipsis, we have $a^2:b^2::AD \times BD (x \times a - x):DE^2$

(y^2) . Hence $y^2 = \frac{b^2}{a^2} \times \frac{ax - x^2}{a - x}$; and the fluxion of the solid, $\dot{s}$

$(= p y^2 \dot{x}) = \frac{p b^2}{a^2} \times \frac{ax - x^2}{a - x} \dot{x}$ and the solidity $s = \frac{p b^2}{a^2} \times$

$\frac{1}{2} ax - \frac{1}{3} x^3 =$ the segment AIE; which, when $AD (x) = AB$

(a) becomes $\left(\frac{p b^2}{a^2} \times \frac{1}{2} a^2 - \frac{1}{3} a^3 \right) \frac{1}{6} p a b^2 =$ the content of the

whole spheroid. Where, if $b (FH)$ be taken $= a (AB)$, we shall also get $\frac{1}{6} p a$ for the true content of the sphere, whose diameter is a . Hence a sphere or spheroid is $\frac{2}{3}$ of its circumscribing cylinder: for the area of the circle FH being expressed by $\frac{p b^2}{4}$, the

content

content of the cylinder, whose diameter is FA, and altitude AB, will be $\frac{pba}{3}$; of which $\frac{2}{3} p a b^2$ is evidently the two-third parts.

PROB. IV. TO COMPUTE THE SURFACE OF ANY SOLID BODY.

(47.) The fluxion of the surface of the solid is equal to the periphery of the surface, by whose motion the solid is generated, multiplied by its velocity on the edge of the solid, and the computation is made as in the foregoing.

Examp. 1. Let it be proposed to determine the convex superficies of a cone ABC, fig. 20, then the semidiameter of the base (BD or CD) being put $= b$, the slanting line, or hypotenuse, AC $= c$, and FH (parallel to DC) $= y$, AH $= z$, the surface $= w$, its fluxion $= \dot{w}$, and p $=$ the periphery of a circle, whose diameter is unity, we shall, from the similarity of the triangles ADC and

Hmh, have $b:c :: y:(mh) \cdot z:(Hh) = \frac{cy}{b}$: whence $\dot{w} = 2py\dot{z}$
 $= \frac{2pcy\dot{y}}{b}$; and consequently $\dot{w} = \frac{pcy\dot{y}}{b}$. This, when $y = h$, be-

comes $= pch = p \times DC \times AC =$ the convex superficies of the whole cone ABC: which therefore is equal to a rectangle under half the circumference of the base and the slanting line.

Examp. 2. To find the surface generated by the cycloidal curve. Put BE, fig. 22, $= z$, FD $= y$, EF $= x$, BD $= a$, s $=$ the surface, and $p = 6.28318$, &c. then from the property of the cycloid it will appear that $\dot{z} = a^{\frac{1}{2}} x^{-\frac{1}{2}} \dot{x}$; therefore $\dot{s} = py\dot{z} = pya^{\frac{1}{2}} x^{-\frac{1}{2}} \dot{x} = p \times a^{\frac{1}{2}} x^{-\frac{1}{2}} \times a^{\frac{1}{2}} x^{-\frac{1}{2}} \dot{x} = pa^{\frac{1}{2}} x^{-\frac{1}{2}} \dot{x} - pa^{\frac{1}{2}} x^{\frac{1}{2}} \dot{x}$; hence $s = 2pa^{\frac{3}{2}} x^{\frac{1}{2}} - \frac{2}{3} pa^{\frac{1}{2}} x^{\frac{3}{2}}$, the surface generated by BE, which needs no correction, since when $s = 0$, $x = 0$; when $x = a$, we have $s = 4pa^2$, equal to the whole surface generated by BA.

(48.) The method of fluxions is also applied to find the centres of gravities, and oscillation of different bodies; to determine the paths described by projectiles acted on by central forces, the resistances to motions in resisting media, the attractions of bodies under different forms, the directions of wind which has the greatest effect on an engine, and to solve many curious and useful problems, as may be seen in the authors on this subject above mentioned. The treatise by Simpson, and that by Vince, deserve particular notice.

FLY, in entomology, a large order of insects, the distinguishing characteristic of which is, that their wings are transparent. By this they are distinguished from beetles, butterflies, grasshoppers, &c. Flies are subdivided into those which have four and those which have two wings. See APIS, FORMICA, CULEX, MUSCA, &c.

FLY, in mechanics, a cross with leaden weights at its ends; or rather a heavy wheel at right angles, to the axis of a windlass, jack, or the like; by means of which, the force of the power, whatever it is, is not only preserved, but equally distributed in all parts of the revolution of the machine. See MECHANICS. The fly may be applied to several sorts of engines, whether moved by men, horses, wind, or water, or any other animate or inanimate power; and is of great use in those parts of an engine which have a quick circular motion, and where the power of the resistance acts unequally in the different parts of a revolution. This has made some people imagine, that the fly adds a new power; but though it may be truly said to facilitate the motion, by making it more uniform, yet upon the whole it causes a loss of power, and not an increase: for as the fly has no motion of its own, it certainly requires a constant force to keep it in motion; not to mention the friction of the pivots of the axis, and the resistance of the air. The reason, therefore, why the fly becomes useful in many engines, is not that it adds a new force to them; but because, in cases where the power acts unequally, it serves as a moderator to make the motion of revolution almost every where equal: for as the fly has accumulated in itself a great degree of power, which it equally and gradually exerts, and as equally and gradually receives, it makes the motion in all parts of the revolution pretty nearly equal and uniform. The very manifest consequence of this is, that the engine becomes more easy and convenient to be acted on and moved by the impelling force; and this is the only benefit obtained by the fly. The best form for a fly, is that of a heavy wheel or circle, of a fit size, as this will not only meet with less resistance from the air, but being continuous, and the weight every where equally distributed through the perimeter of the wheel, the motion will be more easy, uniform, and regular. In this form, the fly is most aptly applied to the perpendicular drill, which it likewise serves to keep upright by its centrifugal force: also to a windlass or common winch, where the motion is quick; for in pulling upwards from the lower part, a person can exercise more power than in thrusting forward in the upper quarter: where, of course, part of his force would be lost, were it not accumulated and conserved in the equable motion of the fly. Hence, by this means, a man may work all day in drawing up a weight of 40lb. whereas 30lb. would create him more labour in a day without the fly.

FLY, in the sea language, that part of the mariner's compass on which the several winds or points are drawn. "Let fly the sheet,"

is a word of command to let loose the sheet, in case of a gust of wind, lest the ship should overset, or spend her top-sails and masts; which is prevented by letting the sheet go a-main, that it may hold no wind.

FLY-BOAT, a large vessel with a double brow, carrying from four to six hundred tons.

FLYERS, in architecture, such stairs as go straight, and do not wind round; nor have the steps made tapering, but the fore and back part of each stair, and the ends, respectively parallel to one another; so that if one flight do not carry you to your intended height, there is a broad half space, from whence you begin to fly with steps every where of the same length and breadth, as before.

FLY-FISHING, the act, or art, of catching fish with a fly. The fly with which the hook is baited may be either natural or artificial; they are made of various sizes and colours according to the sort of fish or the season. See FISHING.

FLY HONEYSUCKLE. See LONICERA, No. 10.

FLY HONEYSUCKLE, AFRICAN. See HALLERIA.

FLYING, the progressive motion of a bird, or other winged animal in the air. The parts of birds chiefly concerned in flying are the wings and the tail: by the former, the bird sustains and wafts himself along; and by the latter, he is assisted in ascending and descending, to keep his body poised and upright, and to obviate the vacillations thereof. It is by the largeness and strength of the pectoral muscles, that birds are so well disposed for quick, strong, and continued flying. These muscles, which in men are scarce a 70th part of the muscles of the body, in birds exceed and outweigh all the other muscles taken together; upon which Mr. Willoughby remarks, that if it be possible for a man to fly, his wings must be so contrived and adapted, that he may use his legs, and not his arms, in managing them. The tail, Messrs. Willoughby, Ray, and many others, imagined to be principally employed in steering and turning the body, as a rudder; but Borelli has put it beyond all doubt, that this is the least use of it. Its chief use is to assist the bird in its ascent and descent in the air, and to obviate the vacillations of the body and wings; for, as to turning the body to this or that side, it is performed by the wings and inclination of the body, and but very little by the help of the tail. The flying of a bird, in fact, is quite a different thing from the rowing of a vessel. Birds do not vibrate their wings towards the tail, as oars are struck towards the stern, but waft them downwards; nor does the tail of the bird cut the air at right angles, as the rudder does the water; but is disposed horizontally, and preserves the same situation what way soever the bird turns. In effect, as a vessel is turned about on its centre of gravity to the right, by a brisk application of the oars to the left; so a bird in beating the air with its right wing alone, towards the tail, will turn its fore-part

to the left. Thus pigeons changing their course to the left would labour it with their right wing, keeping the other almost at rest. Birds of a long neck alter their course by the inclination of their head and neck, which altering the course of gravity, the bird will proceed in a new direction. The act of flying is thus performed: The bird first bends his legs, and springs with a violent leap from the ground; then opens and expands the joints of his wings, so as to make a right line perpendicular to the sides of his body: thus the wings, with all the feathers therein, constitute one continued lamina. Being now raised a little above the horizon, and vibrating the wings with great force and velocity perpendicularly against the subject air, that fluid resists those successions, both from its natural inactivity and elasticity, by means of which the whole body of the bird is protruded. The resistance the air makes to the withdrawing of the wings, and consequently the progress of the bird, will be so much the greater, as the stroke of the fan of the wing is longer: but as the force of the wing is continually diminished by this resistance, when the two forces continue to be in equilibrio, the bird will remain suspended in the same place; for the bird only ascends so long as the arch of air the wing describes makes a resistance equal to the excess of the specific gravity of the bird above the air. If the air, therefore, be so rare as to give way with the same velocity as it is struck withal, there will be no resistance, and consequently the bird can never mount. Birds never fly upwards in a perpendicular line, but always in a parabola. In a direct ascent, the natural and artificial tendency would oppose and destroy each other, so that the progress would be very slow. In a direct descent they would aid one another, so that the fall would be too precipitate.

FLYING, ARTIFICIAL, that attempted by men, by the assistance of mechanics. The art of flying has been attempted by several persons in all ages. The Leucadians, out of superstition, are reported to have had a custom of precipitating a man from a high cliff into the sea, first fixing feathers, variously expanded, round his body, in order to break the fall. Friar Bacon, not only affirms the art of flying possible, but assures us, that he himself knew how to make an engine wherein a man sitting might convey himself through the air like a bird; and further adds, that there was then one who had tried it with success. The secret consisted in a couple of large thin hollow copper globes, exhausted of air; which being much lighter than air, would sustain a chair whereon a person might sit. Fa. Francisco Lana, in his *Prodromo*, proposes the same thing as his own thought. But Dr. Hook proves that this is impracticable. The philosophers of King Charles II's reign were mightily busied about this art. Bishop Wilkins was so confident of success in it, that he says, he does not question but in future ages it will be as usual to hear a man call for his wings, when he is going a journey, as it is now to call for his boots.

FLYING-ARMY, a small body under a lieutenant or major-general, sent to harass the country, intercept convoys, prevent the enemy's incursions, cover its own garrisons, and keep the enemy in continual alarm.

FLYING FISH, a name given to several species of fish, which, by means of their long fins, keep themselves out of water a considerable time. See *EXOCOETUS*.

FLYING PINION, a part of a clock, having a fly or fan to gather air, and so bridle the rapidity of the clock's motion, when the weight descends in the striking piece.

FLY-TRAP, VENUS's, in botany, a singular sensitive plant, lately discovered. See *DIONEÆ*.

FLY-WORT, in botany. See *SILENE*.

FO, or **FOE**, an idol of the Chinese, originally worshipped in the Indies, and transported from thence into China, together with the tables with which the Indian books were filled. He is said to have performed most wonderful things, which the Chinese have described in several volumes, and represented by cuts.

FOCHIA, NOVA, or FOUCHEA, a sea-port town of Asiatic Turkey, in Natolia, on the Gulf of Smyrna. It is 32 miles S. S. W. of Pergamo.

FOCUS, [Lat.] in optics, the point from which rays diverge, or to which they converge. See *OPTICS*.

FOCUS, in conic sections. See *CONIC SECTIONS*.

FODDER, [*fothre, fother*, Sax.] dry food stored up for cattle against winter.

FODDER, in the civil law, is used for a prerogative that the prince has, to be provided of corn and other meats for his verses, by the subjects, in his warlike expeditions.

FODDER, in mining, a measure containing 22 hundred and a half weight, though in London only 20 hundred weight.

FENUGREEK. See *TRIGONELLA*.

FENUS NAUTICUM. Where money was lent to a merchant, to be employed in a beneficial trade upon condition to be repaid, with extraordinary interest, in case such voyage was safely performed, the agreement was sometimes called *fenus nauticum*, sometimes *usura maritima*. But, as this gave an opening for usurious and gaming contracts, 19 Geo. II. c. 37, enacts, that all money lent on bottomry, or at respondentia, on vessels bound to or from the East Indies, shall be expressly lent only upon the ship or merchandise: the lender to have the benefit of salvage, &c. Blackstone's Com. II. 459. Mol. de Jur. Mar. 361.

FETUS, the young of all viviparous animals whilst in the womb, and of oviparous animals before being hatched. The name is transferred by botanists to the embryos of vegetables. Till the young is perfectly formed, it is more properly called Embryo. In the human fetus there exist several peculiarities not to be found in the adult: 1. The arteries of the naval string, which are continuations of the hypogastrics, are after the birth shrivelled up, and form the lower umbilical ligament. 2. The veins of the naval string are formed by the union of all the venous branches in the placenta; and, passing into the abdomen, become the falciform ligament of the liver. 3. The lungs, before being inflated with air, are compact and heavy; but after one inspiration they become light, and as it were spongy: and it may be noted here, that the notion of the lungs sinking in water before the child breathes, and of their swimming after the reception of air, are no certain proofs that the child had or had not breathed, much less that it was murdered: for the uninfused lungs become specifically lighter than water, as soon as any degree of putrefaction takes place in them; and this soon happens after the death of the child; besides, where the utmost care has been taken to preserve the child, it has breathed once or twice, and then died. 6. The thymus gland is very large in the fetus, but dwindles away in proportion as years advance. 7. The foramen ovale in the heart of a fetus is generally closed in an adult.

FOG, or **MIST**, a meteor consisting of gross vapours floating near the surface of the earth. Fogs have a considerable influence on the winter. In the summer of 1783, an uncommon fog prevailed all over Europe, and great part of North America. It was dry, of a permanent nature, and the rays of the sun had but little effect in dissipating it, which they easily do in moist fogs arising from water. The effect of the rays in heating the earth was exceedingly diminished: hence its surface was frozen early, the first snows remained on it undissolved, and received continual additions; the air was more chilled, and intensely cold, and the winter of 1783 and 1784 was exceedingly severe. The spring fogs are most detrimental to such young fruit, and other trees, as are planted in low situations; because they moisten the young shoots, and thus render them more liable to the injuries of the frosty nights succeeding them, but which they escape when placed in more elevated situations.

FOGAGE, or **FOGAGIUM**, in the forest law, rank grass not eaten up in summer.

FOGARAS, a town of Transylvania, on the Alauta, the see of a Greek bishop. It is 26 miles N. E. of Hermanstadt.

FOGO, a small island near the coast of Newfoundland. Lon. 54. 10. W. Lat. 50. 2. N.

FO-HI, FO, or FE, the chief god of the Chinese, whom they adore as the sovereign of heaven. They represent him shining all in light, with his hands hid under his robes, to shew that his power does all things invisibly. He has at his right hand the famous Confucius, and at his left Lanza, or Lanca, chief of the second sect of their religion.

FO-HI is also the name of the first emperor of China, according to the most credible and authentic histories. Some suppose him the same with Noah; others place him 200 years after the deluge. The Chinese say he reigned 115 years.

FOHR, or **FORA**, a fertile island of Denmark, on the coast of Sleswick; 12 miles in circuit. Lon. 8. 31. E. Lat. 54. 44. N.

FOIL, among glass-grinders, a sheet of tin, with quicksilver, or the like, laid on the back side of a looking-glass, to make it reflect. See *FOLIATING*.

FOIL, among jewellers, a thin leaf of metal placed under a precious stone, in order to make it look transparent, and give it an agreeably.

agreeably different colour, either deep or pale: thus, if a stone be wanted to be of a pale colour, put a pale-coloured foil under it, or if deep, a dark one. These foils are made either of copper, gold, or gold and silver together. The copper foils are commonly known by the name of Nuremberg, or German foils.

FOIX, a late county of France, anciently independent, but united to that kingdom by Henry IV. and now included in the department of Arriege.

FOIX, a town of France, in the department of Arriege, 8 miles S. of Pamiers.

FOKIEN, a province of China, bounded on the N. by that of Tche-Kiang; E. by the sea; S. by Quang-tong, and W. by Kiang-Si. It is commodiously situated for navigation and commerce.

FOLD-NET, among sportsmen, a sort of net with which small birds are taken in the night, of which there are two sorts; the less may be managed by one man only, but the greater must be carried by two, and used thus: let the net be fixed on both sides to two strong, straight, and light poles about twelve feet long, each man holding one of them; let there be one behind them, at the distance of two yards, to carry lights: the nets must be carried between the wind and the birds, which all naturally roost on their perches with their breasts against the wind; by reason of this, he that beats the bushes on the other side of the hedge, will drive them out that way towards the light.

FOLIAGE, [*folium*, Lat. *feuillage*, Fr.] leaves; tufts of leaves; the apparel of leaves to a plant.

FOLIAGE, in architecture, used for the representations of flowers, leaves, branches, rinds, &c. whether natural or artificial, as are used for enrichments on capitals, friezes, pediments, &c.

FOLIATE, in the higher geometry, a name given by M. de Moivre to a curve of the second order, expressed by the equation $x^3 + y^3 = axy$; being a species of defective hyperbolas with one asymptote, and consisting of two infinite legs crossing one another, and forming a sort of leaf.

FOLIATING OF GLASS PLATES FOR MIRRORS, the spreading the plates over, after they are polished, with quicksilver, &c. to make them reflect images. It is performed thus: A thin blotting paper is spread on the table, and then a fine lamina or leaf of tin called foil, is laid over the paper; upon this is poured mercury, which is to be distributed equally over the leaf with a hare's foot or cotton: over this is laid a clean paper, and over that the glass plate, which is pressed down with the right hand, and the paper drawn gently out with the left: this being done, the plate is covered with a thicker paper, and loaded with a greater weight, that the superfluous mercury may be driven out and the tin adhere more closely to the glass. When it is dried, the weight is removed, and the looking-glass is complete. Some add an ounce of marcasite, melted by the fire, and lest the mercury should evaporate in smoke, they pour it into cold water; and when cooled, squeeze through a cloth, or through leather. Some add a quarter of an ounce of tin and lead to the marcasite, that the glass may dry the sooner.

FOLIATING OF GLOBE GLASSES FOR MIRRORS, is done as follows: Take five ounces of quicksilver and one ounce of bismuth; of lead and tin, half an ounce each: first put the lead and tin into fusion, then put in the bismuth; and when that is also in fusion, let it stand till it is almost cold, and pour the quicksilver into it: after this, take the glass globe, which must be very clean, and the inside free from dust: make a paper funnel, which put into the hole of the globe, as near the glass as possible, so that the amalgam, when poured in, may not splash, and cause the glass to be full of spots; pour it in gently, and move it about, so that the amalgam may touch every where: if the amalgam begin to be curdly and fixed, hold it over a gentle fire, and it will easily flow again; and if it be too thin, add a little more lead, tin, and bismuth, to it. The finer and clearer the globe is, the better will the looking-glass be. Dr. Shaw observes, that this operation has considerable advantages, as being performable in the cold; and that it is not attended with the danger of poisonous fumes from arsenic, or other unwholesome matters, usually employed for this purpose. How far it may be applicable to the more commodious foliating of the common looking-glasses, and other speculums, he thinks, deserves to be considered.

FOLIFERO-FLORIFEROUS PLANTS, plants that pro-

duce both leaves and flowers. Some plants, as the *Alnus*, produce leaves only: others, as the *Populus*, *Fraxinus*, &c. bear leaves and flowers distinct.

FOLIGNI, FOLIGNO, or FULIGNO, a town of Italy, in the duchy of Spoleto, anciently called Fulginium. It contains eight churches, and twenty-three convents; and is famous for its paper-mills and silk manufactures. It is seated on the side of a mountain, 15 miles N. of Spoleto, and 69 N. of Rome.

FOLIO, among printers and booksellers the largest form of books, when each sheet is so printed, that it may be bound up in two leaves only. This form is only used in large works; but the quarto or octavo forms are much more handy.

FOLIO, in merchant's book, denotes a page, or rather both the right and left hand pages, these being expressed by the same figure, and corresponding to each other. See **BOOK-KEEPING**.

FOLIS. See **FOLLIS**.

FOLIUM, or **LEAF**, in botany. See **LEAF**.

FOLKES, MARTIN, an English antiquary, mathematician, and philosopher, born at Westminster about 1690, greatly distinguished as F. R. S. London, and of the Academy of Sciences at Paris. He was admitted into the former at 24 years of age; made one of their council two years after; named by Sir Isaac Newton himself as vice-president; and, after Sir Hans Sloan, became president. There are numerous Memoirs of his in the Philosophical Transactions. Coins, ancient and modern, were his great object: and his last production was a book upon the "English Silver Coin, from the Conquest to his own Times." He died at London in 1754. Dr. Birch drew up materials for his life, which are preserved in the Anecdotes of Bower, p. 562, et seq.

FOLKESTONE, a town of Kent, between Dover and Hythe, appears to have been a very ancient place, from the Roman coins and British bricks often found in it. It is 7 miles S. W. of Dover, and 72 E. S. E. of London.

FOLK-LANDS, or FOLC-LANDS, [*Sax.*] copyhold lands, so called in the time of the Saxons, as charter-lands were called *boc-lands*, Kitch. 174. Folkland was terra vulgi or popularis; the land of the vulgar people, who had no certain estate therein, but held the same, under the rents and services accustomed or agreed, at the will only of their lord the thane; and it was therefore not put in writing, but accounted *prædium rusticum et ignobile*. Spelm. of Feuds, c. 5.

FOLKMOTE, or FOLCMOTE, [*Folcgemot*, *Sax. i. e. a meeting of the people*,] is compounded of *folk*, the people, and *mote*, or *gemote*, to meet; and signified originally, as Somner in his Saxon Dictionary informs us, a general assembly of the people, to consider of and order matters of the commonwealth. And Sir Henry Spelman says, the folcmote was a sort of annual parliament, or convention of the bishops, thanes, aldermen, and freemen, upon every May-day yearly; where the laymen were sworn to defend one another and the king, and to preserve the laws of the kingdom; and then consulted the common safety. But Dr. Brady infers from the laws of the Saxon kings of England, that it was an inferior court, held before the king's reeve or steward, every month, to do folk right, or compose smaller differences, from whence there lay appeal to the superior courts; Gloss. p. 48. Squire seems to think the folcmote not distinct from the shiremot, or common general meeting of the county. See his *Angl. Sax. Gov.* 155. n.

FOLKMOTE was also used for any kind of popular or public meeting; as of all the tenants at the court-leet, or court-baron.

FOLLICLE, [*folliculus*, Latin,] in botany, the seed-vessels; capsula seminalis, or case; which some fruits and seeds have over them; as that of the alkengi, pedicularis, &c.

FOLLICULI are defined by Linnaeus to be small glandular vessels distended with air, which appear on the surface of some plants; as at the root of water milfoil, and on the leaves of *aldrovanda*. In the former, the vessels in question are roundish with an appearance like two horns; in the latter, pot-shaped, and semi-circular.

FOLLICULUS, [from *follis*, Lat. a bag,] is also a species of seed-vessel, first mentioned by Linnaeus, in his "Delinatio Plantarum."

FOLLIS, or FOLIS, anciently signified a little bag or purse; whence it came to be used for a sum of money, and very different sums were called by that name.

FOMAHANT,

FOMAHANT, in astronomy, a star of the first magnitude in the mouth of the Southern Fish.

FOMENTATION, in medicine, the bathing of any part of the body with a convenient liquor; which is usually a decoction of herbs, water, wine, or milk; and the applying of bags stuffed with herbs and other ingredients, which is commonly called dry fomentation.

FOMENTATIONS are usually applied as warm as the patient can bear, in the following manner: Two flannel-cloths are dipped into the heated liquor, one of which is wrung as dry as the necessary speed will admit, then immediately applied to the part affected; it lies on until the heat begins to go off, and the other is in readiness to apply at the instant in which the first is removed: thus these flannels are alternately applied, so as to keep the affected part constantly supplied with them warm. This is continued fifteen or twenty minutes, and repeated two or three times a-day. Every intention of relaxing and soothing by fomentations may be answered as well by warm water alone, as when the whole tribe of emollients are boiled in it; but when discutients or antiseptics are required, such ingredients must be called in as are adapted to that end. The degree of heat should never exceed that of producing a pleasing sensation; great heat produces effects very opposite to that intended by the use of fomentations.

FONDI, 1. a town, and 2. a lake of Naples in the province of Lavora; 50 miles S. E. of Rome.

FONG-YANG, a city of China, in the province of Kiangnan, situated on a mountain, which hangs over the Yellow river, and incloses with its walls several fertile little hills. Its jurisdiction is very extensive, comprehending 18 cities; five of which are of the second, and 13 of the third class.

FONS, a town of France, in the department of Lot, $4\frac{1}{2}$ miles N. W. of Figeac.

FONT, among ecclesiastical writers, a large basin, in which water is kept for the baptizing of infants, or other persons. It is so called probably because baptism was usually performed among the primitive Christians at springs or fountains. In process of time the font came to be used, being placed at the lower end of the church, to intimate, perhaps, that baptism is the rite of admission into the Christian church.

FONT, in the art of printing, denotes a complete assortment of types for letters, accents, &c. See **FOUNT**.

FONTAINBLEAU, a town of France, in the department of Seine and Marne, 35 miles S. E. of Paris. Lon. 2. 47. E. Lat. 48. 25. N.

FONTAINE, **JOHN DE LA**, a French poet, was born at Chateau-Thierry in 1621. He was educated first at Rheims, and afterwards under the fathers of the Oratory. He was a man of excessive simplicity of manners, credulous, fearful, and uncommonly absent. He lived for some time with the superintendent Fouquet, who allowed him a pension. Afterwards he was in the service of Princess Henrietta of England, and next lived with Madame de la Sabliere. He was married, but his wife had as little knowledge of economy as himself. He died in 1693, and on being laid out, a hair shirt was found next his skin. His Tales are very licentious, but his Fables are usually put into the hands of young people. They are very natural, poetical, and entertaining. He also wrote "Les Amours de Psyché," a romance; some comedies; Letters, &c. to be found in his miscellanies.

FONTAINE, **L'EVEQUE**, in the department of the North, and late province of Hainault, 3 miles W. of Charleroi, and 10 E. of Mons.

FONTAINES, **PETER FRANCIS**, a French critic, born at Rouen in 1685. At 15, he entered into the society of the Jesuits, and at 30 quitted it, though he was a priest, and had a cure in Normandy. Having excited some attention at Paris by his critical productions, the Abbé Bignon in 1724 committed to him the "Journal de Scavans." He was peaceably enjoying the applauses of the public, when his enemies, whom he had raised by his critical strictures in his Journal, accused him of a most abominable crime, and procured him to be imprisoned. He was set at liberty in fifteen days; the magistrate of the police justified him in a letter to the Abbé Bignon; and he was unanimously re-established in his former credit, in 1725. In 1731, he began a work entitled "Novelliste du Parnasse, ou Reflexions sur les Ouvrages Nouveaux;" but only proceeded to two volumes; the work hav-

ing been suppressed by authority, from the incessant complaints of authors ridiculed therein. In 1735, he obtained a new privilege for a periodical production, entitled, "Observations sur les Ecrits Modernes;" which, after continuing to 33 volumes was suppressed in 1743. Yet in 1744, he published another weekly paper, called, "Jugemens sur les Ouvrages Nouveaux," which proceeded to 11 volumes: the two last being done by other hands. In 1745, he was attacked with a disorder in the breast, which ended in a dropsy that proved fatal in five weeks. "He was (says M. Freron) born a sentimental person; a philosopher in conduct as well as in principle; exempt from ambition, and of a noble firm spirit, which would not submit to sue for preferments or titles. In common conversation he appeared only a common man; but when any thing out of the ordinary way was agitated, he discovered great force of imagination and wit." He was the author of many other works; his biographer mentions 17 articles; many of them critical, some historical, and some translations from Pope, Swift, Fielding, &c. The Abbé de la Porte, published in 1737, "L'Esprit de l'Abbé des Fontaines," in four volumes 12mo.; with his Life, a catalogue of his works, and of writings against him.

FONTANELLA, in anatomy, the quadrangular aperture betwixt the os frontis and ossa sincipitis, in children just born; also called fons pulsatilis.

FONTANELLA, in geography, a rich town of Italy, in the Cremonese.

FONTANESIA, in botany, a genus of the diandria monogynia class and order. Natural order, Separiæ. Calyx four-parted, inferior; petals two, two-parted; capsule membranaceous, not opening, two-celled; cells one-seeded. It has one species.

FONTARABIA, a sea-port town of Spain in Biscay, and in the territory of Guipuscoa. Lon. 1. 47. W. Lat. 43. 22. N.

FONTENELLE, **BERNARD DE**, a celebrated French author, born in 1657. He discharged the office of perpetual secretary to the Academy of Sciences above forty years with universal applause; and his History of that Academy throws great light upon their memoirs. The elogies he pronounced on the deceased members of the Academy excite a respect for the sciences, as well as for the author. In his poetical performances, and his "Dialogues of the Dead," the spirit of Voiture was discernible, though more extended and more philosophical. His "Plurality of Worlds," is a singular work, the design of which was to present that part of philosophy to view in a pleasing dress. He died in 1756, near 100 years old.

FONTENOY, a town of France, in the department of Jemappes, late Austrian Netherlands, and province of Hainault, 4 miles S. S. E. of Tournay.

FONTES, a town of France, in the department of Herault, 6 miles N. W. of Montagnac.

FONTEVRAULD, a town of France, in the department of Maine and Loire, and late province of Anjou. It is 6 miles S. E. of Saumur, and 160 S. W. of Paris.

FONTEVRAULD, or **FRONTEVAUX**, **ORDER OF**, in ecclesiastical history, a religious order instituted by Robert d'Arbrissel, about the end of the 11th century; taken under the protection of the holy see, by Pope Pascal II. in 1106; confirmed by a bull in 1113, and invested by his successors with extraordinary privileges. The chief of this order is a female, who is appointed to inspect both the monks and the nuns.

FONTINALIA, or **FONTANALIA**, in antiquity, a religious feast held among the Romans in honour of the deities who presided over fountains or springs.

FONTINALIS, in botany, a genus of the cryptogamia musci, or Mosses. Capsule oblong, with the mouth ciliate; opening with an acuminate lid; covered with a sessile, smooth, conical veil; included in a pitcher-shaped, imbricate perichætium. Only four species are known, they are natives of England: three of them are water-mosses, and one grows upon trees. Professor Martyn says, that several new species have been discovered by Swartz in the West Indies.

FOOD, [*fædan*, Sax. *voeden*, Dut. to feed,] in the most extensive signification of the word, implies all aliments taken into the body, whether solid or fluid; but, in common language, it is generally used to signify only the solid part. Lord Monboddo and other authors, who are fond of representing mankind as origi-

nally

nally very little, if at all, wiser than brutes, tell us, that, in the first ages, men lived upon acorns, berries, and such fruits as the earth spontaneously produces; that they next proceeded to eat the flesh of wild animals taken in hunting; but the number of these decreasing, and mankind multiplying, necessity taught them the art of cultivating the ground, sowing corn, &c. That after this, reason suggests the expedient of domesticating certain animals, both to assist them in their labours and supply them with food: that hogs were the first animals of the domestic kind that appeared upon their tables; that they held it to be ungrateful to devour the beasts that assisted them in their labours, &c. But all this is at best conjectural, unsupported by any better authority, than that of the fabulous Herodotus. Nay the fact seems to be, that animal and vegetable food, such as we now use, were both made use of in the very first age of the world. Moses, the most ancient, as well as the most authentic of historians, informs us, that "Abel was a keeper of sheep, and Cain a tiller of the ground;" whence we may fairly presume, that sheep were then kept and fed, as they now are, for the sake of their mutton; for we cannot suppose the woollen manufacture to have been among the most early inventions, though the skins untanned might serve for cloathing. As to cookery, it is supposed, and seems not improbable, that all animal food was at first only roasted, and that boiling was a later invention. Even in the present age the inhabitants of Otaheite are said to have been entirely unacquainted with it, till the Europeans visited them. The eating of fish too seems also to have been of a much later date than that of flesh. Homer makes Menelaus complain that they had been constrained to eat them. Though originally designed to be a blessing to mankind, as well as their support, food may, in many cases, by our abuse of it, be justly considered as a curse: for we do not hesitate to affirm, that the injudicious conduct of parents and nurses, during infancy, and the early years of childhood, lays the foundation of those numerous diseases, which, at a maturer age arise from indigestion, and have, in many families, become hereditary. The aliment of children ought to be adapted to their age, and the strength of their digestive powers. Hence they ought by no means to be fed immoderately, and promiscuously with every kind of food: as, by this indulgence, the first passages are distended, and their stomachs gradually acquire an unnatural craving for victuals, before the preceding meal is properly assimilated. Such conduct is particularly injurious during the first year of their age: for, when their stomachs become more vigorous, they may be enabled, by slow degrees, to digest different kinds of victuals, the nature and properties of which are extremely opposite; though excess in quantity is always hurtful. No food whatever, that has been prepared for many hours, should be given to children, especially after being warmed up, as it generates flatulence, heart-burn, costiveness, and a variety of disorders which are equally painful and difficult to remove. Sudden changes from liquid to solid food are equally dangerous: one kind of aliment only, should be given at each meal, in moderate portions; and not a multiplicity of incongruous mixtures, in immediate succession, such as broth or soup, meat boiled or roasted, after taking milk, fruit, &c. All stimulating dishes, prepared for adults, as well as beer, wine, spices, coffee, and other heating liquors, should be carefully withheld from children; as they often occasion the most afflictive complaints, for instance, eructations, vomiting, spasms, and convulsions, especially during dentition; and, if the hapless victims of indulgence survive that period, they become liable to other tormenting diseases, the most frequent of which are the scurvy, scrophula, and consumption. There is another abuse in the feeding of children, which cannot be too seriously reprehended, namely, to introduce chewed victuals into their mouth, a practice equally disgusting and unwholesome. Young and healthy mothers, it has been said, may safely perform this office for their children: but, in such case, it is requisite that the parent be in a complete state of health, that she be provided with sound teeth, and rinse her mouth previously with pure water. Under these circumstances, she may venture to perform mastication, though it would be more advisable to relinquish this practice, and to give infants such food only as they are able to chew and digest. Vegetables are, with a few exceptions, more difficult of digestion than animal food; but a due proportion of both, with the addition of acids, during the summer months, is alike grateful and conducive to health. On the whole,

the flesh of young quadrupeds is less nutritive than after they have attained a proper age; though it will, in general, be more easily converted into alimentary matter. In a salted state, meat not only loses a considerable part of its gelatinous and spirituous particles, but it likewise becomes oppressive to the digestive organ, and imparts a degree of acrimony to the human fluids, which has a remarkable tendency to generate putrid diseases, such as the scurvy of mariners. Hence it would be a desirable object to ascertain, by accurate experiments, whether beef, pork, &c. might not be kept fresh at sea for many months, merely by burying it in charcoal-powder, of which it could be easily divested by proper ablution. Such is our decided opinion, and we venture to recommend this important subject to the farther researches of patriotic inquirers. With respect to the quantity of food, there is one general rule, which ought never to be disregarded; namely, to cease eating, when the first cravings of appetite are satisfied, so as to renovate the waste which the body has apparently sustained. By a strict adherence to this principle, many of those distressing complaints arising from intemperance, might be effectually obviated; and our fashionable watering-places would not be so frequently crowded by the victims of luxury.

FOOD OF PLANTS, an expression in agriculture and gardening, by which is understood whatever tends to increase the growth, or affords nourishment to vegetable productions. The proper choice and distribution of this food, in such manner as to ensure the greatest advantage to vegetation, is an object deserving the most attentive exertion of every skilful husbandman. The component parts of the nourishment of plants are supposed to be air, heat, water, earth, and nitre; but it is by no means ascertained, which of these ingredients principally contributes to their growth and reproduction. Various opinions have been held respecting the existence of an aerial acid spirit; but, from the late discoveries in chemistry, this invisible agent appears to be no other than what is now termed oxygen gas, or the acidifying principle, by the powerful influence of which even iron is oxidated, or converted into rust: and, as this vital gas is an essential constituent of the atmosphere, all plants necessarily partake of its animating properties. Thus nitre is said to nourish them; because it contains a large portion of oxygen; though it is certain that saltpetre only prepares other substances to effect that purpose: thus, if nitre, in a solid or liquid state, be applied to the root of a plant, it will destroy it; but if it be placed at a distance, it attenuates, and decomposes, the viscous and naturally pernicious matters contained in the earth, so as to render them fit for supplying vegetables with nutriment. Water contributes to the growth of plants in a very material degree: hence arose the art of floating land in dry seasons, without which vegetables would perish for want of moisture. See IRRIGATION. Air, on account of its elasticity, is absolutely necessary to the increment of vegetables; warmth is of equal importance, because no plant can thrive without some degree of heat. But, doubtless, the chief article is earth; which, being prepared by the nitrous, and other volatile salts, such as are generated in dung, not less than by water and air, is assimilated to the nature of plants; constitutes a part of them; and is inseparable from them: but, if water, air, and heat, be taken away, the plant will still exist; though, from the want of those elements, it has ceased to vegetate. The excess of nitre, air, water, and heat, however, is a proof that these articles do not constitute the proper, or only food of plants. Thus, too great a proportion of nitre, or other salts, corrodes, and deprives them of vegetable life; too much water drowns them; too great a degree of air dries their roots: and too much heat shrivels and burns them; but there cannot be too large a proportion of earth, unless the plant be too deeply buried under it, so as to exclude the salutary influence of the other elements; in which case it must necessarily perish. Many experiments have lately been made with factitious gases, in order to ascertain whether the growth of plants might be forwarded by such artificial agents; but, though some of these elastic airs, such as oxygen have been found remarkably to promote vegetation, yet the expence and trouble, which these applications would occasion in the great way, will ever be insuperable objections to their general introduction. From recent attempts to fertilize and stimulate the soil itself, as the growing medium, with chemical solutions, it appears that water very slightly impregnated with camphor, or, according to others, with

the phosphoric acid, has produced uncommon effects on the earth of vegetables, and accelerated their rapid growth in a very evident manner. Farther experiments, however, will decide how far such means are practicable, and whether the nature of plants thus forced, is materially changed or affected.

FOOSHT, an island in the Red Sea; situated, according to the observations of Mr. Bruce, in N. lat. $15^{\circ} 59' 43''$.

FOOT, that part of the body on which animals stand and walk. The principal cause of the lameness and distortion observable among many children, especially of the poorer class, is owing to an improper management of them, during their infancy. Instead of being carried on the nurses' arms, in a posture which contracts and palsies the lower extremities, they ought to be supported in such a direction that the legs and feet may be at liberty. Nor should they be confined too early in narrow shoes, with a view to render their feet small and taper: those necessary parts of our dress ought to be wide enough to allow sufficient room for motion, and might be fastened with strings, which are preferable to buckles. It will also be proper to adapt the shoes to the form of each foot, by means of separate lasts; in the same manner as those of the fashionable classes are made at present. A kind of half-boots, however, such as may be laced above the ankles, are superior to shoes, as they not only have the advantage of fitting the leg, but are likewise not easily trodden down at the heels; besides children are enabled to walk more firmly in them than in shoes. With respect to the feet of adults, we would recommend always to adapt the shoe to their size and shape, and utterly to disregard the prevalence of an absurd fashion, which is often attended with inconvenience. Animals are distinguished, with respect to the number of their feet, into bipedes, two-footed; such are men and birds: quadrupedes, four-footed; such are most land-animals: and multipedes, or many-footed, as insects. The reptile-kind, as serpents, &c. have no feet; the crab-kind of fish have gotten feet, but most other fishes have no feet at all: the spider, mites, and polypuses, have eight; flies, grasshoppers, and butterflies, have six feet. Animals destined to swim, and waterfowl, have their toes webbed together, as the phocæ, goose, duck, &c. The fore-feet of the mole, rabbit, &c. are wonderfully formed for digging and scratching up the earth, in order to make way for their head.

Foot, in anatomy. See **ANATOMY**.

Foot, in the Latin and Greek poetry, a measure, composed of a certain number of long and short syllables. They are commonly reckoned 28: of these some are simple, as consisting of two or three syllables, and therefore called dissyllabic or trissyllabic feet; others compound, consisting of four syllables, and therefore called tetrasyllabic feet. The dissyllabic feet are four in number, viz. the pyrrhichius, spondeus, iambus, and trocheus. See **PYRRHICHIVS**, &c. The trissyllabic feet are eight in number, viz. the dactylus, anapestus, tribrachys, molossus, amphibrachys, amphimacer, bacchius, and antibacchius. See **DACTYLUS**, &c. The tetrasyllabic are 16 in number, viz. the procleumaticus, spondeeus, choriambus, antispastus, diambus, dichoreus, ionicus a minore, ionicus a minore, epitritus primus, secundus, tertius, et quartus, pæon primus, secundus, tertius, et quartus. See **PROCLESMATICUS**, &c.

Foot, a long measure containing 12 inches: it is divided by geometricians into 10 digits, and the digit into 10 lines. See **MEASURE**.

Foot of a Horse, in the manege, the extremity of the leg, from the coronet to the lower part of the hoof. See **FARRIERY**.

Foot, Solid or Cubic, is the same measure in all the three dimensions, length, breadth, and depth or thickness, containing 1728 cubic inches.

Foot, Square, is the same measure both in breadth and length, containing 144 square or superficial inches.

FOOTE, SAMUEL, an English dramatic writer and actor, was born at Truro, in Cornwall, in 1722. His father was a justice of peace for that county, and his mother sister to Sir John Dinely Goodere, of Herefordshire. Foote was educated at Worcester College, Oxford, from whence he removed to the Temple; but as the dryness of this study did not suit the liveliness of his genius, he soon relinquished it. He married a young lady of a good family and some fortune; but their tempers not agreeing, harmony did not long subsist between them. He now launched into gaming and all the fashionable follies of the age; and in a few years spent his whole fortune. His necessities led him to the stage, and

he made his first appearance in *Othello*. In 1747 he opened the little theatre in the Haymarket, with a dramatic piece of his own, called, *The Diversions of the Morning*, which succeeded very well. The exhibition next season, was called *An Auction of Pictures*, in which he took off some of the most noted characters of the day. He still continued to play at one or the other of the theatres, and frequently produced new pieces. In 1760 he brought out the *Minor* at his own house in the Haymarket. In 1766 he had the misfortune to break his leg, which was obliged to be amputated. The duke of York, out of compassion, procured for him a patent for life for the theatre in the Haymarket. In 1776 he attacked the duchess of Kingston in a piece, which was suppressed by authority. Soon after this a man-servant, whom he had dismissed, charged him with an unnatural offence; of which he was honourably acquitted. He died at Dover, on his way to France for his health, in Oct. 1777. His remains were interred in Westminster abbey. Foote had an infinite fund of comic humour, both in writing and conversation; but he took unwarrantable liberties in taking off persons merely on account of natural failings and peculiarities of manner. His farces have procured him the title of the English *Aristophanes*.

Foot-Halt, a disorder incident to sheep. It takes its source from an insect, which, when it comes to a certain maturity; resembles a worm of 2, 3, or 4 inches in length. The first appearance of this malady is, when the sheep gives signs of lameness, which increase to so high a degree as to prevent grazing; when, with want of sufficient food, and pain, the poor animal suffers greatly, and lingers till it dies, if not cured by extracting the insect or worm. The sooner this is done the better, as it is easily performed. As soon as the lameness is perceived, let the foot that is lame be examined between the close of the claws, and it will be found that in the skin where the close separates is a small hole (not natural,) through which the insect, when yet small, gets its entrance, and by degrees has worked itself upwards along the leg, between the outward skin and bone, and obtains its largest magnitude. Proportionally it finds its nourishment, when it is left undisturbed. This worm must be extracted by moving the claws backward and forward in contrary directions: when the under part of the worm will soon make its appearance at the above-mentioned small hole, and continuing the same operation of moving the claws, the whole worm will work itself out. This is better than at its first appearance to draw it out with danger of breaking off; lest part of it should remain in the sheep's leg, and, by rotting there, prove hurtful. This easy operation will be effectual without any application whatever, and the channel, which the worm hath made along the leg, will cure of itself. This malady is in some years more prevalent than in others, particularly in wet seasons; and is oftener observed to begin in spring and autumn than in summer and winter; notwithstanding sheep suffer more by the wet in winter than in any of the other seasons. In high grounds, they are less liable to it than in low marshy and meadow grounds; from all which circumstances it may be supposed, that this insect, in its first state, has for its most natural element either the earth, water, or air; and only gets accidentally between the close of the claws of the sheep, and finds there what is sufficient for its nourishment and security.

Foot-Geld, or **FAUT-GELD**, in our old customs, an amercement laid upon those who live within the bounds of a forest, for not lawing or cutting out the ball of their dog's feet. To be free of a foot-geld, was a privilege to keep dogs unclawed, within the bounds of a forest.

Foot-Level, among artificers, an instrument that served as a foot-rule, a square, and a level. See **LEVEL**, **RULE**, and **SQUARE**.

Foot-Pace, or **HALF-PACE**, among carpenters, a pair of stairs, whereon, after four or six steps, you arrive at a broad place, where you may take two or three paces before you ascend another step. The design of which is to ease the legs in ascending the rest of the steps.

Foot-Rot, a disease to which sheep are subject, and which is said to be contagious. The first symptom of the disorder is manifest, when the animal affected begins to limp; though no injury will be perceptible on examining the foot, which is extremely hot. The second stage of the distemper is a yellowish-white spot, that appears in the cleft of the hoof, spreads gradually, and becomes livid; destroying the hair, which in sound animals covers the foot. At this period, the diseased part acquires a disagreeable smell,

smell, and the lameness increases. In the third stage, the malady sinks into the frog of the foot; the shell of the hoof loosens, and the frog is filled with fetid matter, that oozes out when pressed by the hand: a small tumor sometimes breaks out in the front of the leg, about one inch above the hoof, which, however, is easily dispersed. In the last stage, the foot is so completely mortified by the cancerous humour corroding every part of it, as to become incurable; in which case, the skin is the only valuable part of the animal. Through these different periods, the sheep affected retain their appetite, and feed apparently as well as when in health; but they very soon fall away, and continue to decline, till they have lost all their fat. Notwithstanding their rapid decay, at the end of the second and the commencement of the third stage, they are so eager for food, that they even crawl on their knees for sustenance. For the cure of this infectious disorder, different remedies have been prescribed; from which we select the following: the first was invented by the late Mr. Bakewell, the other by Mr. George Culley, of Fenton, Northumberland. 1. Take 3 oz. of verdigrise; of vitriol, and common alum, 4 oz. each; white mercury $1\frac{1}{2}$ oz. and white copperas, 1 oz. The whole is to be finely pulverized, and dissolved in a quart of white-wine vinegar. 2. Let 4 oz. of the best honey; 2 oz. of burnt alum reduced to powder, and $\frac{1}{2}$ lb. of pulverized Armenian bole, be mixed in as much train or fish-oil as will convert these ingredients into the consistence of salve: the honey ought first to be gradually dissolved, when the Armenian bole should be properly stirred in, after which the alum and train-oil are to be added. The parts affected may be rubbed with either of these compositions; unless the distemper has become incurable; but in the opinion of Mr. Arthur Young, the red salve of Mr. Culley, is more efficacious than Mr. Bakewell's liquid; having cured one or two diseased feet, where the latter had failed: yet Mr. Young always employs the liquid, previously to anointing the animals with the salve. This malady, in general, arises from long grass in wet seasons; but, if sheep be suffered to lie upon their own dung, a fermentation will take place, and occasion either the foot-rot, or the foot-halt: to prevent which fatal disorders, those animals should be well littered, and kept with a strict attention to cleanliness.

FORADADA, a small island in the Mediterranean, near Majorca.

FORAGE, in military affairs, implies hay, straw, and oats, for the subsistence of the army horses. It is divided into rations, of which one is a day's allowance for a horse, and contains 20lb. of hay, 10lb. of oats, and 5lb. of straw. When cavalry is stationed in barracks in Great Britain, the number of rations of forage is, to field-officers four, supposing them to have four effective horses; to captains three; to staff-officers two; to quarter-masters, non-commissioned officers, and privates, each one. On foreign service, this article is governed by circumstances.

FORAMEN, in anatomy, a name given to several apertures or perforations in divers parts of the body; as, 1. The external and internal foramina of the cranium or skull. 2. The foramina in the upper and lower jaw. 3. Foramen lachrymale. 4. Foramen membranae tympani. See **ANATOMY**.

FORBES, DUNCAN, Esq. of Culloden, an eminent Scots lawyer and judge, born in 1685. In his early life, he was brought up in a family remarkable for hospitality; which, perhaps, led him afterwards to a free indulgence in social pleasures. His natural disposition inclined him to the army, but, as he soon discovered a superior genius, by the advice of his friends he applied himself to the civil law; in which he made a quick progress, and, in 1709, was admitted an advocate. From 1722 to 1737, he represented the boroughs of Inverness, Fortrose, Nairn, and Forres. In 1725, he was made king's advocate; and in 1737, Lord President. In 1714 and 1745 he espoused the royal cause, but conducted himself with so much prudence and moderation, that not a whisper was at any time heard to his prejudice. The glory he acquired in advancing the prosperity of his country, and in contributing to re-establish peace and order, was his only reward. He died in 1747. His lordship was a man of great piety and learning, and well versed in the Hebrew scriptures, as appears from his Letter to a Bishop on Hutchinson's Writings and Discoveries, in 1732; Thoughts concerning Religion, natural and revealed, 1735; and Reflections on Incredulity; the whole collected into one volume, 12mo. 1750. His works have since been published in two vols. 8vo.

FORBES, PATRICK, bishop of Aberdeen, was born in 1554, when the affairs of the church of Scotland were in much confusion; to the settlement of which he greatly contributed. As chancellor of the university of Aberdeen, he improved that seat of learning by repairing the fabric, augmenting the library, and reviving the professorships. He published a Commentary on the Revelation at London, 1613; and died in 1635.

FORBES, JOHN, the son of Patrick, but of much more extensive learning than his father, was perhaps excelled by none of his age, which will be allowed by those who read his Historical and Theological Institutes. He was also bishop of Aberdeen; but was expelled by the Covenanters, and forced to fly beyond sea. He continued in Holland two years; and, upon his return, lived privately on his estate at Corse, till he died in 1648. His works were printed in two vols. folio at Amsterdam in 1703.

FORCALQUIER, a town of France in the department of the Lower Alps, on the Laye, 20 miles N. E. of Aix.

FORCE, in philosophy, denotes the cause of the change in the state of a body, when being at rest, it begins to move, or has a motion which is either not uniform or not direct. While a body remains in the same state, either of rest or of uniform and rectilinear motion, the cause of its remaining in such a state is in the nature of the body, and it cannot be said that any extrinsic force has acted on it; if two equal and opposite forces be applied, they destroy each other. This internal cause or principle is called Inertia. Mechanical forces may be reduced to two sorts; one of a body at rest, the other of a body in motion. The force of a body at rest, is that which we conceive to be in a body lying still, on a table, or hanging by a rope, or supported by a spring, &c. and this is called by the names of pressure, tension, force, or vis mortua, sollicitatio, conatus movendi, conamen, &c. To this class also of forces we must refer Centripetal, and Centrifugal forces, though they reside in a body in motion; because these forces are homogeneous to weights, pressures, or tensions of any kind. The force of a body in motion is a power residing in that body so long as it continues its motion; by means of which it is able to remove obstacles lying in its way; to lessen, destroy, or overcome, the force of any other moving body, which meets it in an opposite direction; or to surmount any dead pressure or resistance, as tension, gravity, friction, &c. for some time; but which will be lessened or destroyed by such resistance as it lessens or destroys the motion of the body. This is called vis motrix, moving force, and by some late writers vis viva, to distinguish it from the vis mortua spoken of before; and by these appellations, however different, the same thing is understood by all mathematicians, viz. that power of displacing, of withstanding opposite moving forces, or of overcoming any dead resistance, which resides in a moving body, and which, in whole or in part, continues to accompany it, so long as the body moves. See **MECHANICS**.

FORCE, COMPARATIVE OF MEN AND HORSES. There are several curious as well as useful observations in Desagulier's Experimental Philosophy, concerning the comparative forces of men and horses, and the best way of applying them. A horse draws with the greatest advantage when the line of direction is level with his breast; in such a situation, he is able to draw 200lb. 8 hours a-day, walking about two miles and an half an hour. And if the same horse be made to draw 240lb. he can work but six hours a-day, and cannot go quite so fast. On a carriage, indeed, where friction alone is to be overcome, a middling horse will draw 1000 lb. But the best way to try a horse's force is by making him draw up out of a well, over a single pulley or roller; and in such a case, one horse with another will draw 200lb. Five men are found to be equal in strength to one horse, and can, with as much ease, push round the horizontal beam of a mill, in a walk 40 feet wide; whereas three men will do it in a walk only 19 feet wide. The worst way of applying the force of a horse, is to make him carry or draw up hill; for if the hill be steep, three men will do more than a horse, each man climbing up faster with a burden of 100lb. weight, than a horse that is loaded with 300lb. a difference which is owing to the position of the parts of the human body, being better adapted to climb than those of a horse. On the other hand, the best way of applying the force of a horse, is in an horizontal direction, wherein a man can exert least force; thus a man, weighing 140lb. and drawing a boat along by means of a rope coming over his shoulders, cannot draw above 27lb. or exert above one-seventh part of the force of a horse employed on the same

same purpose. The very best and most effectual posture in a man, is that of rowing; wherein he not only acts with more muscles, at once for overcoming the resistance, than in any other position; but as he pulls backwards, the weight of his body assists by way of lever. See Desaguliers, Exp. Phil. vol. i. p. 241, where we have several other observations relative to force acquired by certain positions of the body, from which that author accounts for most feats of strength and activity. See also a Memoir on this subject by M. de la Hire, in Mem. Roy. Acad. Sc. 1629; or in Desaguliers, Exp. &c. p. 267, &c. who has published a translation of part of it with remarks.

FORCE, ACCELERATIVE, or RETARDIVE FORCE, is that which respects the velocity of the motion only, accelerating or retarding it; and it is denoted by the quotient of the motive force, divided by the mass or weight of the body. So, if m denote the motive force, and b the body, or its weight, and f the accelerating or retarding force, then is $f = \frac{m}{b}$. Again, forces are either constant or va-

riable. Constant forces are such as remain and act continually the same for some determinate time. Such, for example, is the force of gravity, which acts constantly the same upon a body, while it continues at the same distance from the centre of the earth, or from the centre of force, wherever that may be. In the case of a constant force F , acting upon a body b , for any time t , we have these following theorems; putting $f =$ the constant accelerating force $= F \div b$; $v =$ the velocity at the end of the time t ; $s =$ the space passed over in that time, by the constant action of that force on the body: and $g = 16\frac{1}{2}$ feet, the space generated by gravity in 1 second, and calling the accelerating force of gravity 1; then is

$$s = \frac{1}{2}tv = gft^2 = \frac{v^2}{4gf}; v = 2gft = \frac{v^2}{t} = \sqrt{4gfs}; t = \frac{v}{2gf}$$

$$= \frac{2s}{v} = \sqrt{\frac{s}{gf}}; f = \frac{s}{2gt} = \frac{v^2}{4gs}$$

FORCES, VARIABLE, are such as are continually changing in their effect and intensity; such as the force of gravity at different distances from the centre of the earth, which decreases in proportion as the square of the distance increases. In variable forces, theorems similar to those above may be exhibited, by using the fluxions of quantities, and afterwards taking the fluents of the given fluxional equations. And herein consists one of the great excellencies of the Newtonian or modern analysis, by which we are enabled to manage and compute the effects of all kinds of variable forces, whether accelerating or retarding. Thus, using the same notation as above for constant forces, viz. f , the accelerating force at any instant; t , the time a body has been in motion by the action of the variable force; v , the velocity generated in that time; s , the space run over in that time; and $g = 16\frac{1}{2}$ feet; then is

$$s = \frac{v^2}{2gf} = vt; v = \frac{v^2}{v} = 2gft; t = \frac{v}{2gf}; f = \frac{v^2}{2gs}$$

In these four theorems, the force f , though variable, is supposed to be constant for the indefinitely small time t ; and they

are to be used in all cases of variable forces, as the former ones in constant forces; viz. from the circumstances of the problem under consideration, deduce a general expression for the value of the force f , at any indefinite time t ; then substitute it in one of these theorems, which shall be proper to the case in hand; and the equation thence resulting will determine the corresponding values of the other quantities in the problem. It is also to be observed, that the foregoing theorems equally hold good for the destruction of motion and velocity, by means of retarding or resisting forces, as for the generation of the same by means of accelerating forces.

FORCE, in law, signifies any unlawful violence offered to things or persons, and is divided into simple and compound.

I. FORCE, COMPOUND, is where some other violence is committed with such an act which of itself alone is criminal; as if one enters by force into another's house, and there kills a person, or ravishes a woman. There is likewise a force implied in law, as in every trespass, rescue, or disseisin, and an actual force with weapons, number of persons, &c.—Any persons may lawfully en-

ter a tavern, inn, or victualling house; so may a landlord his tenant's house to view repairs, &c. But if, in these cases, the person that enters commits any violence or force, the law will intend that he entered for that purpose.

II. FORCE, SIMPLE, is what is so committed, that it has no other crime attending it; as where a person by force enters on another's possession, without committing any other unlawful act.

FORCELLAR, a town of Naples, in the province of Abruzzo Ultra, 3 miles E. of Teramo.

FORCEPS, a pair of nippers, or pinchers, for laying hold of and pulling out any thing forced into another body.

FORCEPS, in surgery, &c. a pair of scissors for cutting off, or dividing, the fleshy or membranous parts of the body. See **SURGERY**.

FORCER, or **FORCING-PUMP**, in mechanics, is a kind of pump in which there is a forcer or piston without a valve. See **PUMP**.

FORCIBLE DETAINER, in law, is where one by violence withholds the possession of lands, &c. so that the person who has a right of entry is barred, or hindered, therefrom.

FORCIBLE ENTRY is, a violent and actual entry into houses or lands. At common law, any person that had a right to enter into lands, &c. might retain possession of it by force. But this liberty being abused, to the breach of the peace, it was therefore found necessary that the same should be restrained: Though, at this day, he who is wrongfully dispossessed of goods may by force retake them. By statute, no persons shall make an entry on any lands or tenements, except where it is given by law, and in a peaceable manner, even though they have title of entry, on pain of imprisonment: and where a forcible entry is committed, justices of peace are authorized to view the place, and enquire of the force by a jury, summoned by the sheriff of the county; and they may cause the tenements, &c. to be restored, and imprison the offenders till they pay a fine. A writ of forcible entry also lies, where a person seised of a freehold, is by force put out thereof.

FORCIBLE MARRIAGE, of a woman of estate, is felony. For by the statute 3 Hen. 7. c. 2, it is enacted, "That if any persons shall take away any woman having lands or goods, or that is heir apparent to her ancestor, by force, and against her will, and marry or defile her; the takers, procurers, abettors, and receivers, of the woman taken away against her will, and knowing the same, shall be deemed principal felons; but as to procurers and accessories, they are, before the offence be committed, to be excluded the benefit of clergy, by 39 Eliz. c. 9. The indictment on the statute 3 H. 7. is expressly to set forth, that the woman taken away had lands or goods, or was heir apparent; and also that she was married or defiled, because no other case is within the statute; and it ought to allege that the taking was for lucre." It is no excuse that the woman at first was taken away with her own consent: for if she afterwards refuse to continue with the offender, and be forced against her will, she may from that time properly be said to be taken against her will; and it is not material whether a woman so taken away be at last married or defiled with her own consent or not, if she were under force at the time; the offender being in both cases equally within the words of the act. Those persons who, after the fact, receive the offender, are but accessories after the offence, according to the rules of common law; and those that are only privy to the damage, but not parties to the forcible taking away, are not within the act, H. P. C. 119. A man may be indicted for taking away a woman by force in another country; for the continuing of the force in any country amounts to a forcible taking there. Ibid. Taking away any woman-child under the age of 16 years and unmarried, out of the custody and without the consent of the father or guardian, &c. the offender shall suffer fine and imprisonment; and if the woman agree to any contract of matrimony with such person, she shall forfeit her estate during life, to the next of kin to whom the inheritance should descend, &c. Stat. 4 & 5. P & M. c. 8. This is a force against the parents: and an information will lie for seducing a young man or woman from their parents, against their consents, in order to marry them, &c. See **MARRIAGE**.

FORCING, in gardening, a method of producing ripe fruits from trees before their natural season. The method of doing it is this: A wall should be erected ten feet high; a border must be marked out on the south side of it, of about four feet wide, and some stakes must be fastened into the ground all along the edge of the

the border; these should be four inches thick. They are intended to rest the glass lights upon, which are to slope backwards to the wall, to shelter the fruit as there shall be occasion: and there must be, at each end, a door to open either way, according as the wind blows. The frame should be made moveable along the wall, that when a tree has been forced one year, the frame may be removed to another, and so on, that the trees may each of them be forced only once in three years, at which rate they will last a long time. They must be always well-grown trees that are chosen for forcing; for young ones are soon destroyed, and the fruit that is produced from them is never so well tasted. The fruits most proper for this management are the avant or small white nutmeg, the albermarle, the early Newington, and the brown nutmeg peaches; Mr. Fairchild's early, and the elrugo and Newington nectarines; the masculine apricot, and the may-duke and may-cherry. For grapes, the white and black sweet-water are the properest; and of gooseberries the Dutch white, the Dutch early green, and the walnut goose-berry; and the large Dutch white and large Dutch red currants. The dung, before it is put to the wall, should be laid in a heap for five or six days, that it may heat thoroughly; and when thus prepared it must be laid four feet thick at the base of the wall, and go sloping up till it is two feet thick at the top. It must be laid at least within three or four inches of the top of the wall; and when it sinks, as it will sink two or three feet, more dung must be laid on; for the first heat will do little more than just swell the blossom buds. The covering of the trees with glasses is of great service; but they should be taken off to admit the benefit of gentle showers to the trees, and the doors at the ends should be either left entirely open, or one or both of them opened, and a mat hung before them, at once to let the air circulate and keep off the frosts. The dung is never to be applied till towards the end of November; and three changes of it will be sufficient to ripen the cherries, which will be very fine in February. As to the apricots, grapes, nectarines, peaches, and plums, if the weather be milder, the glasses are to be opened to let in sunshine or gentle showers. If a row or two of scarlet strawberries be planted at the back of the frame, they will ripen in February or the beginning of March; the vines will blossom in April, and the grapes will ripen in June. It should be carefully observed, not to place early and late ripening fruits together, because the heat necessary to force the late ones will be of great injury to the early ones after they have fruited.

FORCING, in the wine trade, a term used by the wine coopers, for the fining down wines, and rendering them fit for immediate draught.

FORDSAND, a small island of Denmark, near the coast of Sleswick. Lon. 8. 35. E. Lat. 55. 1. N.

FORDWICH, a town of Kent, called in the Domesday Book "the little Borough of Fordwich," is a member of the port of Sandwich, and was anciently incorporated by the style of the barons of the town of Fordwich, but more lately by the name of the mayor, jurats, and commonalty, who enjoy the same privileges as the cinque-ports. It is famous for excellent trouts, taken in the Stour.

FORDYCE, DAVID, an elegant and learned writer of the 18th century, was professor of philosophy in the Marischal college, Aberdeen. He was originally designed for the ministry; to prepare himself for which was the whole aim of his ambition, and for a course of years the whole purpose of his studies. How well he was qualified to appear in that character, appears from his Theodorus, a dialogue concerning the art of preaching. After having finished this work, he went abroad on his travels, to obtain fresh stores of knowledge: but after a successful tour through several parts of Europe, he was unfortunately cast away in a storm on the coast of Holland. He wrote also Dialogues on Education, 8vo. and a Treatise of Moral Philosophy, published in the Preceptor. The third edition of his Theodorus was published in London, after his untimely death, by his brother, the Rev. Mr. James Fordyce, an eminent dissenting minister, in 1755.

FORE, applied to a ship, denotes that part of her frame and machinery which lies near the stern.

FORE AND AFT is used for the whole ship's length, or from end to end.

FORE-CASTLE OF A SHIP, that part where the fore-mast stands. It is divided from the rest by a bulk-head. See the article SHIP.

VOL. II.—NO. 87.

FORE-CLOSED, in law, signifies the being shut out, and excluded, or barred, the equity of redemption on mortgages, &c.

FORE-FOOT, in the sea-language, signifies one ship's lying, or sailing, cross another's way: as if two ship's being under sail, and in ken one of another, one of them lying in her course with her stem so much a weather the other, that holding on their several ways, neither of them altering their courses, the windward ship will run a-head of the other: then it is said, such a ship lies with the other's forefoot.

FOREIGN, in the English law, is used in various significations. Thus,

1. **FOREIGN ATTACHMENT**, is an attachment of the goods of foreigners found within a city or liberty, for the satisfaction of some citizen to whom the foreigner is indebted; or it signifies an attachment of a foreigner's money in the hands of another person.

2. **FOREIGN KINGDOM**, a kingdom under the dominion of a foreign prince. At the instance of an ambassador or consul, any offender against the laws here may be sent for hither from a foreign kingdom to which he hath fled. And, where a stranger of Holland, or any foreign country, buys goods at London, for instance, and there gives a note under his hand for payment, and then goes away privately into Holland; in that case, the seller may have a certificate from the lord mayor, on the proof of the sale and delivery of such goods, whereupon a process will be executed on the party in Holland.

3. **FOREIGN OPPOSER**, or **APPOSER**, an officer in the exchequer that opposes or makes a charge on all sheriffs, &c. of their green wax; i. e. fines, issues, amerciaments, recognizances, &c.

4. **FOREIGN PLEA**, signifies an objection to the judge of the court, by refusing him as incompetent, because the matter in question is not within his jurisdiction.

5. **FOREIGN SEAMEN**, serving two years on board British ships, whether of war, trade, or privateers, during the time of war, shall be deemed natural-born subjects.

FOREIGNERS, though made denizens, or naturalized, are disabled to bear any office in government, to be of the privy council, or members of parliament, &c. This is by the acts of the settlement of the crown. Such persons as are not freemen of a city or corporation, are also called foreigners, to distinguish them from the members of the same.

FOREJUDGER, a judgement whereby a man is deprived, or put out, of the thing in question.

FOREJUDGED THE COURT, is when an officer or attorney of the court of common-pleas is expelled the same for some offence, or for not appearing to an action by bill filed against him; and in the latter he is not to be re-admitted till he shall appear. By 2 Hen. IV. c. 8, he shall lose his office and be fore-judged the court.

FORELAND, NORTH, a promontory of England on the N. E. extremity of the isle of Thanet, in Kent, ascertained by act of parliament to be the most southern part of the port of London, which is thence extended N. in a right line to the point, called the Nase on the coast of Essex, and forms the mouth of the Thames. A round brick tower near 80 feet high, was erected here, as a sea-mark, by the Trinity House corporation. It has a light house on its top, in which lights are kept burning every night. The sea gains so much upon the land here by the winds at S. W. that, within the memory of persons still living, about 30 acres of land have been lost in one place. It is $2\frac{1}{2}$ miles S. E. of Margate. Longitude of the light-house, $1^{\circ} 26' 22''$ E. from Greenwich. Latitude of the same, $51^{\circ} 22' 40''$ N.

FORELAND, SOUTH, a promontory of England on the E. coast of Kent, between Dover and Deal, which forms the east point of the Kentish shore, and is called South, in respect to its bearing from the other Foreland, and is about six miles to the N. Their situation is of great security to the noted road between them, called the Downs, which would be very dangerous for ships; did not this point break the sea off, that would otherwise come rolling up from the W. to the Flats or sand-banks, which for three leagues together, and a about a league and a half from the shore, run parallel with it, and are dry at low water. Lon. $1^{\circ} 22' 6''$ E. Lat. $51^{\circ} 8' 21''$ N.

FORELAND, SOUTH, a cape on the W. coast of North America, in Cook's river. Lon. $121. 20. W.$ Lat. $60. 50. N.$

FORELOCKS, in the sea-language, little flat wedges made of E.

with iron, used at the ends of bolts to keep them from flying out of their holes.

FORE-MAST OF A SHIP, a large round piece of timber, placed in her fore-part, or fore-castle, and carrying the fore-sail and fore-top-sail yards. Its length is usually eight-ninths of the main-mast, and the fore-top-gallant-mast is one-half the length of the fore-top.

FORE-MAST MEN, are those on board a ship that take in the top sails, sling the yards, furl the sails, bowse, trice, and take their turn at the helm, &c.

FORE-REACH, in the sea-language: a ship is said to fore-reach upon another, when both sailing together, one sails better, or out-goes the other.

FORESCHOK, in our old authors, signifies the same with forsaken, and is particularly used in one of our statutes for lands or tenements seised by the lord for want of services performed by his tenant, and quietly held by such lord above a year and a day, without any due course of law taken by the tenant for recovery thereof; here he does in presumption of law disavow or forsake all the rights he has thereto, for which reason those lands shall be called foreschoke.

FORESKIN, in anatomy. See **PREPUCE**.

FOREST, in geography, a huge wood; or, a large extent of ground covered with trees. The word is formed of the Latin *foresta*, which first occurs in the capitulars of Charlemagne, and which itself is derived from the German *frost*, signifying the same thing. Spelman derives it from the Latin *foresta restat*, by reason forests are out of towns. Others derive *foresta* from *feris*, q. d. *Foresta, quoad sit tuta statio ferarum*, as being a safe station or abode for wild beasts. The principal forests in this country are those of Sherwood, Windsor, the New Forest, that of Dean, on the north of the river Severn, and Epping Forest, in the county of Essex. There are, besides, several smaller forests, the total extent of which, together with those just enumerated, amounts to about 300,000 acres. The utility of forests, to a commercial nation, is very great; as, by the quantity of timber they afford, a considerable expence may be saved, which must otherwise be incurred by the importation of materials for ship-building. Independently of these considerations, forests of a moderate extent are a national ornament, especially if they do not occupy such lands as could be more usefully employed in agriculture. Formerly, England abounded with woods, and was celebrated for its lofty and majestic oak, which, however, of late years has become scarce. On the contrary, various large tracts of uncultivated ground might now be advantageously planted with larch, fir, and other trees; but, as these expensive undertakings are beyond the ability of private individuals, it is to be hoped that the commissioners of the land revenue will be able speedily to carry so patriotic a measure into effect.

FORESTS, in law, are waste grounds belonging to the king, replenished with all manner of beasts of chase or venery, which are under the king's protection, for the sake of his royal recreation and delight; and to that end, and for preservation of the king's game, there are particular laws, privileges, courts, and officers, belonging to the king's forests. 1 Black. 279. The forest-courts are, the courts of attachments, of regard, of swainmote, and of justice-seat. The court of attachments is to be held before the verderers of the forest, once in every forty days, to enquire of all offenders against the king's deer, or covert for the game, who may be attached by their bodies, if found in the very act of transgression, otherwise by their goods; and in this court the foresters are to bring in their attachment, or presentments of vert and venison: and the verderers are to receive the same, and to inroll them, and to certify them under their seals, to the court of justice-seat, or swainmote; for this court can only inquire of, but not convict, offenders. The court of regard or survey of dogs is to be holden every third year, for the lawing or expeditating of mastiffs, which is done by cutting off the claws of the fore-feet, to prevent them from running after deer. No other dogs than mastiffs were permitted to be kept within the king's forests, it being supposed that the keeping of these, and these only, was necessary for the defence of a man's house. The court of swainmote is to be holden before the verderers as judges, by the steward of the swainmote, thrice in every year, the swains or freeholders within the forest composing the jury. The jurisdiction of this court is, to enquire into the oppressions and grievances committed by the officers of the forest,

and to receive and try presentments certified from the court of attachments, against the offenders in vert and venison; and this court may not only enquire, but convict also, which conviction shall be certified to the court of justice-seat, under the seals of the jury, for this court cannot proceed to judgement. The court of justice-seat, is the principal court; which is held before the chief justice in eyre, or chief itinerant judge, or his deputy, to hear and determine all trespasses within the forest, and all claims of franchises, liberties, and privileges, and all pleas and causes whatsoever therein arising. It may also proceed to try presentments made in the inferior courts of the forest, and to give judgement upon the convictions that have been made in the swainmote courts. It may be held every third year. This court may fine and imprison, it being a court of record; and a writ of error lies to the court of king's bench. 1 Black. 289. 2 Black. 38. 3 Black. 71. But the forest-laws have long ago ceased to be put in execution. 1 Black. 289.

FORESTS, ANTIQUITY OF. Forests are of such antiquity in England, that, excepting the New Forest in Hampshire, erected by William the Conqueror, and Hampton Court, erected by Henry VIII. it is said, that there is no record or history which makes any certain mention of their erection, though they are mentioned by several writers and in several statutes. Ancient historians tell us, "that New forest was raised by the destruction of 22 parish-churches, and many villages, chapels, and manors, for the space of 30 miles together, which was attended with divers judgements on the posterity of William I. who erected it."

FOREST, BLACK, or SCHWARTZWALD, an extensive forest of Germany, in Suabia, on the right side of the Rhine, consisting chiefly of mountains, which run across the greatest part of Suabia from N. to S. and from E. to W. This forest lies chiefly between the late Helvetic republic, the Rhine, and the kingdom of Wurtemberg.

FOREST TOWNS, in geography, four towns of Germany, in Suabia, lying along the Rhine, and the confines of Switzerland, and subject to the house of Austria. Their names are Rhinefeld, Seckingen, Lausenbourg, and Waldshut.

FORE-STAFF, an instrument used at sea for taking the altitudes of heavenly bodies, so called, because the observer, in using it, turns his face towards the object; in contradistinction to the back-staff, where he turns his back to the object. The fore-staff, or cross-staff, represented in Plate LXX, fig. 12, consists of a straight square staff, A B, graduated like a line of tangents and four crosses or vanes, F F, E E, D D, C C, which slide thereon. The first and shortest of these vanes, F F, is called the ten cross, or vane, and belongs to that side of the instrument whereon the divisions begin at 3° and end at 10°. The next longer vane, E E, is called the thirty cross, belonging to that side where the divisions begin at 20° and end at 30°, called the thirty scale. The next vane, D D, is called the sixty cross, and belongs to that side where the divisions begin at 20° and end at 60°. The last and longest, C C, called the ninety-cross, belongs to the side whereon the divisions begin at 30° and end at 90°. The great use of this instrument is to take the height of the sun and stars, or the distance of two stars; and the 10, 30, 60, or 90, crosses, are to be used according as the altitude is greater or less; that is, if the altitude be less than 10°, the ten cross is to be used; if above ten, but less than thirty, the thirty cross is to be used, &c. For altitudes greater than 30°, this instrument is not so convenient as a quadrant or semicircle. To observe an altitude by this instrument, apply the flat end of the staff to your eye, and look at the upper end of the cross for the centre of the sun or star, and at the lower end for the horizon, as represented in fig. 13. If you see the sky instead of the horizon, slide the cross a little nearer the eye: and if you see the sea instead of the horizon, slide the cross farther from the eye: and thus continue moving till you see exactly the sun or star's centre by the top of the cross, and the horizon by the bottom thereof. Then the degrees and minutes, cut by the inner edge of the cross upon the side of the staff peculiar to the cross you use, give the altitude of the sun or star. If the meridian altitude be wanted, continue your observation as long as you find the altitude increase, still moving the cross nearer to the eye. By subtracting the meridian altitude thus found from 90°, you will have the zenith-distance. To work accurately, an allowance must be made for the height of the eye above the surface of the sea, viz. for one English foot, 1 minute; for 5 feet, 2½; for 10 feet, 3½; for 20 feet, 5; for 40 feet,

feet, 7, &c. These minutes subtracted from the altitude, and added to the zenith-distance observed, give the true altitude and zenith-distance. To observe the distance of two stars, or that of the moon from a star, apply the instrument to the eye, and looking to both ends of the cross, move it nearer or farther from the eye till you see the two stars, the one on the one end, and the other on the other end of the cross; then the degrees and minutes cut by the cross, on the side proper to the vane in use, give the star's distance.

FORE-STALLING, is the buying of, or bargaining for, corn, cattle, or other merchandize, in its passage to fairs, or markets, for sale, with an intent to dispose of them again at an advanced price. The punishment for this offence, on conviction by two or more witnesses is, for the first time, two months imprisonment, and forfeiture of the goods, or their value; for the second, the offender incurs an imprisonment of six months, and loses double the value of the articles; and, for the third offence, he is liable to imprisonment during the king's pleasure; to a forfeiture of all his property; and is to be sentenced to stand in the pillory. Severe, however, as these regulations appear, they have hitherto not been attended with the desired effect. Notwithstanding all the arguments and invectives that have been employed against this growing evil, in printed works, and in the courts of justice, we are persuaded that it will never be crushed, till national councils adopt proper and effectual measures for preventing this iniquitous practice.

FORESTERS, officers of the forest, appointed by the king's letters patent, and sworn to walk the forest at all hours, and watch over the vert and venison; also to make attachments and true presentments, of all trespasses committed within the forest. If a man comes into a forest by night, a forester cannot lawfully beat him before he makes some resistance; but in case such a person resists the forester, he may justify a battery. And a forester shall not be questioned for killing a trespasser that, after the peace cried to him, will not surrender himself, if it be not done on any former malice; though, where trespassers in a forest, &c. kill a person that opposes them, it is murder in all, because they were engaged in an unlawful act, and therefore malice is implied to the person killed.

FORETS, a department of France, formed out of the late province of Austrian Luxemburg. Luxemburg is the chief city.

FOREZ, a late province of France, bounded on the N. by Burgundy and Bourbonnois, E. by Lyonnais, S. by Velais and Vivarois, and W. by Auvergne. It now forms, with the Lyonnais, the department of Rhone and Loire.

FORFAR, ANGUS, or FORFAR-SHIRE, a county of Scotland. See **ANGUS**.

FORFAR, an ancient royal burgh of Scotland, capital of the county. It lies 14 miles W. of Montrose, and 14 N. of Dundee. Lon. 2. 54. W. Lat. 56. 35. N.

FORFEITURE, originally signifies a transgression or offence against some penal law. The word is formed of the base Latin *forisfactura*: whence *forisfactura* and *forfactura*, and the French *forfait*. *Forisfactura* comes of *forisfacere*; which, according to Isidore, signifies to hurt or offend; *facere contra rationem*; and which is not improbably derived of *foris*, out, and *facere*, to do, *q. d.* an action out of rule, or contrary to the rules. Borel will have *forfait* derived from the using of force or violence: Lobbineau in his glossary will have *forisfact* properly to signify a mulct or amend, not a forfeit; which last he derives from the base British *aforfed*, a penalty. But it is now more frequently used for the effect of such transgression; or the losing some right, privilege, estate, honour, office, or effects, in consequence thereof, than for the transgression itself. Forfeiture differs from confiscation, in that the former is more general; while confiscation is particularly applied to such things as become forfeited to the king's exchequer; and goods confiscated are said to be such as nobody claims. Forfeitures may be either in civil or criminal cases.

I. FORFEITURE IN CIVIL CASES. A man who has an estate for life or years, may forfeit it many ways, as well as by treason or felony; such as alienation, claiming a greater estate than he hath, or affirming the reversion to be in a stranger, &c. When a tenant in tail makes leases not warranted by statute; a copyholder commits waste, refuses to pay his rent, or do suit of court; and where an estate is granted upon condition, on non-performance whereof, &c. they will make a forfeiture. Entry for a forfeiture

ought to be by him who is next in reversion, or remainder, after the estate forfeited. As if the tenant for life or years commits a forfeiture, he who has the immediate reversion or remainder ought to enter, though he has the fee, or only an estate tail.

II. FORFEITURE IN CRIMINAL CASES, is two-fold; of real, and personal estates.

1. FORFEITURE OF PERSONAL ESTATES. The forfeiture of goods and chattels accrues in every one of the high kinds of offence; in high treason, or misprision thereof, petit treason, felonies of all sorts whether clergyable or not, self-murder, or felony de se, petty larceny, standing mute, &c. For flight also, on an accusation of treason, felony, or even petit larceny, whether the party be found guilty or acquitted, if the jury find the flight, the party shall forfeit his goods and chattels; for the very flight is an offence, carrying with it a strong presumption of guilt, and is at least an endeavour to elude and stifle the course of justice prescribed by the law. But the jury very seldom find the flight; forfeiture being looked upon, since the vast increase of personal property of late years, as too large a penalty for an offence to which a man is prompted by the natural love of liberty. There is a remarkable difference or two between the forfeiture of lands, and of goods and chattels. (1.) Lands are forfeited upon attainder, and not before; goods and chattels are forfeited by conviction. Because in many of the cases where goods are forfeited, there never is any attainder; which happens only where judgement of death or outlawry is given; therefore, in those cases, the forfeiture must be upon conviction, or not at all; and being necessarily upon conviction in those, it is so ordered in all other cases, for the law loves uniformity. (2.) The forfeiture of lands has relation to the time the fact was committed, so as to avoid all subsequent sales and incumbrances; but the forfeiture of goods and chattels has no relation backwards; so that those only which a man has at the time of conviction shall be forfeited. Therefore a traitor or felon may bona fide sell any of his chattels, real or personal, for the sustenance of himself and family between the fact and conviction; for personal property is of so fluctuating a nature, that it passes through many hands in a short time; and no buyer could be safe, if he were liable to return the goods which he had fairly bought, provided any of the prior vendors had committed a treason or felony. Yet if they be collusively and not bona fide parted with, merely to defraud the crown, the law (and particularly the statute 13 Eliz. c. 5.) will reach them; for they are all the while truly and substantially the goods of the offender; and as he, if acquitted, might recover them himself, as not parted with for a good consideration; so, in case he happens to be convicted, the law will recover them for the king.

2. FORFEITURE OF REAL ESTATES. By attainder in high treason, says Blackstone, a man forfeits to the king all his lands and tenements of inheritance, whether fee-simple or fee-tail; and all his rights of entry on lands and tenements, which he had at the time of the offence committed, or at any time afterwards, to be for ever vested in the crown; and also the profits of all lands and tenements, which he had in his own right for life or years, so long as such interest shall subsist. This forfeiture relates backwards to the time of the treason committed; so as to avoid all intermediate sales and incumbrances, but not those before the fact; and therefore a wife's jointure is not forfeitable for the treason of her husband; because settled upon her previous to the treason committed. But her dower is forfeited, by the express provision of statute 5 and 6 Edw. VI. c. 11. And yet the husband shall be tenant by the courtesy of the wife's lands, if the wife be attainted of treason; for that is not prohibited by the statute. But, though after attainder the forfeiture relates back to the time of the treason committed, yet it does not take effect unless an attainder be had, of which it is one of the fruits; and therefore, if a traitor dies before judgement pronounced, or is killed in open rebellion, or is hanged by martial law, it works no forfeiture of his lands: for he never was attainted of treason. But if the chief justice of the king's bench (the supreme coroner of all England) in person, upon the view of the body of him killed in open rebellion, records it and returns the record into his own court, both lands and goods shall be forfeited. The natural justice of forfeiture or confiscation of property, for treason is founded on this consideration: that he who hath thus violated the fundamental principles of government, and broken his part of the original contract between king and people,

ple, hath abandoned his connections with society, and hath no longer any right to those advantages which before belonged to him purely as a member of the community; among which social advantages, the right of transferring or transmitting property to others is one of the chief. Such forfeitures, moreover, whereby his posterity must suffer as well as himself, will help to restrain a man, not only by the sense of his duty, and dread of personal punishment, but also by his passions and natural affections; and will interest every dependent and relation he has to keep him from offending: according to that beautiful sentiment of Cicero, "*nec vero me fugit quam sit acerbum, parentum scelera filiorum panis lui: sed hoc præclare legibus comparatum est, ut caritas liberorum amiciores parentes reipublica redderet.*" And therefore Aulus Cascellius, a Roman lawyer in the time of the triumvirate, used to boast that he had two reasons for despising the power of the tyrants; his old age and his want of children: for children are pledged to the prince of the father's obedience. Yet many nations have thought, that this posthumous punishment savours of hardship to the innocent; especially for crimes that do not strike at the very root and foundation of society, as treason against the government expressly does. And therefore, although confiscations were very frequent in the times of the earlier emperors, yet Arcadius and Honorius, in every other instance but that of treason, thought it more just, *ibi esse penam, ubi et noxa est*; and ordered, that "*peccata suos teneant auctores, nec ulterius progrediatur metus quam reperiatur delictum.*" and Justinian also made a law to restrain the punishment of relations; which directs the forfeiture to go, except in the case of crimen majestatis, to the next of kin to the delinquent. On the other hand, the Macedonian laws extended even the capital punishment of treason, not only to the children, but to all the relations of the delinquent; and of course their estates must be also forfeited, as no man was left to inherit them. And in Germany, by the famous golden bull (copied almost verbatim, from Justinian's code), the lives of the sons of such as conspire to kill an elector are spared, as it is expressed, by the emperor's particular bounty. But they are deprived of all their effects and rights of succession, and are rendered incapable of any honour ecclesiastical and civil: to the end that, being always poor and necessitous, they may for ever be accompanied by the infamy of their father; may languish in continual indigence; and may find (says this merciless edict) their punishment in living, and their relief in dying." In England, forfeiture of lands and tenements to the crown for treason is by no means derived from the feudal policy, but was antecedent to the establishment of that system in this island; being transmitted from their Saxon ancestors, and forming a part of the ancient Scandinavian constitution. But in certain treasons relating to the coin (which seem rather a species of the crimen falsi than the crimen læsæ majestatis,) it is provided by some of the modern statutes which constitute the offence, that it shall work no forfeiture of lands, save only for the life of the offenders; and by all, that it shall not deprive the wife of her dower. And, in order to abolish such hereditary punishment entirely, it was enacted by statute 7 Ann. c. 21, that, after the decease of the late pretender, no attainder for treason should extend to the disinheriting of any heir, nor to the prejudice of any person, other than the traitor himself. By which the law of forfeitures for high treason would by this time have been at an end, had not a subsequent statute intervened to give them a longer duration.

FORFEX, in Roman antiquity, a way of drawing up an army in the form of a pair of shears. It was intended to receive the cuneus or wedge, if the enemy should make use of that figure. For when the forfex opened to admit the wedge, they had an opportunity of defeating their design, and cutting them in pieces.

FORFICULA, the **EAR-WIG**, in zoology, a genus of insects of the order coleoptera. Antennæ bristly; feelers unequal; elytra dimidiated; wings covered; tail forked. This genus of insects is one of the best known, the forceps at the extremity of their abdomen forming a very distinctive character. It is this seeming weapon that has occasioned those insects to be called forficula; and the formidable name of ear-wigs has been given them in English, from a notion that the insect frequently introduces itself into the ears, causing great pain and even death. Mr. Barbut, however, assures us, that the forceps which the ear-wig carries at his tail, and with which he seems provided for his defence, is not so formida-

ble as it at first appears, being destitute of strength sufficient to produce the least sensible impression. The larva differs very little from the perfect insect. Ear-wigs are very mischievous vermin in gardens, especially where carnations are preserved; for they are so fond of these flowers, that if care be not taken to prevent them, they will entirely destroy them, by eating off the sweet parts at the bottom of the leaves. To prevent which, most people have stands erected, which have a bason of earth or lead round each supporter, which is constantly kept filled with water. Others hang the hollow claws of crabs and lobsters upon sticks in divers parts of the garden into which those vermin get; and by often searching them, one will destroy them without much trouble, which will be of great service to the wall-fruit. This genus has eighteen species.

FORGE, properly signifies a little furnace, wherein smiths and other artificers of iron or steel, &c. heat their metals red-hot, to soften them, and render them more malleable and manageable on the anvil. An ordinary forge is nothing but a pair of bellows, the nozzle of which is directed upon a smooth area, on which coals are placed. The nozzle of a pair of bellows may be also directed to the bottom of any furnace, to excite the combustion of the coals placed there, by which a kind of forge is formed. In laboratories, there is generally a small furnace consisting of one cylindrical piece, open at top, which has at its lower side a hole for receiving the nozzle of a double bellows. This kind of forge furnace is very convenient for fusions, as the operation is quickly performed, and with few coals. In its lower part, two inches above the hole for receiving the nozzle of the bellows, may be placed an iron plate of the same diameter, supported upon two horizontal bars, and pierced near its circumference with four holes diametrically opposite to each other. By this disposition, the wind of the bellows, pushed forcibly under this plate, enters at these four holes; and thus the heat of the fire is equally distributed, and the crucible in the furnace is equally surrounded by it. This contrivance is used in the forge furnaces for melting copper, with this difference only, that, these furnaces are square, which is a matter of no consequence. As the wind of bellows strongly and rapidly excites the action of the fire, a forge is very convenient when a great heat is to be applied quickly: but it is not suitable when the heat is to be gradually increased. The forge, or blast of bellows, is used in several operations in small; as to fuse salts, metals, ores, &c. It is also much used in works in the grate, which require strong heat, without much management; and chiefly in the smelting of ores, and fusion of metallic matters.

FORGE, is also used for a large furnace, wherein iron ore, taken out of the mine, is melted down: or it is more properly applied to another kind of furnace, wherein the iron ore, melted down and separated in a former furnace, and then cast into sows and pigs, is heated and fused over again, and beaten afterwards with large hammers, and thus rendered more soft, pure, ductile, and fit for use.

FORGE, in the train of artillery, is generally called a travelling forge, and may not be improperly called a portable smith's shop; at this forge all manner of smith's work is made, and it can be used upon a march as well as in camp. Formerly they were very ill contrived, with two wheels only, and wooden supporters to prop the forge for working when in the park. Of late they are made with four wheels, which answers their purpose much better.

FORGE FOR RED-HOT BALLS, is a place where the balls are made red-hot before they are fired off: it is built about five or six feet below the surface of the ground, of strong brick-work, and an iron grate, upon which the balls are laid, with a very large fire under them.

FORGERY, in law, is the fraudulent imitation of a name, or alteration of a writing to the prejudice of another man's right. By statute 5 Eliz. c. 14, to forge or make, or knowingly to publish or give in evidence, any forged deed, court-roll, or will, with intent to affect the right of real property, either freehold or copyhold, is punished by a forfeiture to the party aggrieved of double costs and damages; by standing in the pillory, and having both his ears cut off, and his nostrils slit, and seared; by forfeiture to the crown of the profits of his lands, and by perpetual imprisonment. For any forgery relating to a term of years or annuity bond, obligation, acquittance, release, or discharge, of any debt, or demand of any personal chattels, the same forfeiture is given to the

the party grieved; and on the offender is inflicted the pillory, loss of one of his ears, and half a year's imprisonment: the second offence, in both cases, being felony without benefit of clergy. Besides this general act, a multitude of others, since the revolution, when paper credit was first established, have inflicted capital punishment on the forging, altering, or uttering, as true, when forged, of any bank bills or notes, or other securities; of bills of credit issued from the exchequer; of south-sea bonds, &c.; of lottery tickets or orders; of army or navy debentures; of East India bonds; of writings under the seal of the London or royal exchange assurance; of the hand of the receiver of the prebends, or of the accountant-general and certain other officers of the chancery; of a letter of attorney or other power to receive or transfer stock or annuities; and on the personating a proprietor thereof, to receive or transfer such annuities, stock, or dividends: also on the personating, or procuring to be personated, any seaman or other person, entitled to wages or other naval emoluments, or any of his personal representatives; and the taking, or procuring to be taken, any false oath in order to obtain a probate or letters of administration, in order to receive such payments; and the forging, or procuring to be forged, and likewise the uttering or publishing, as true, of any counterfeited seaman's will or power: to which may be added, though not strictly reducible to this head, the counterfeiting of Mediterranean passes, under the hands of the lords of the admiralty, to protect one from the piratical states of Barbary; the forging or imitating of any stamps to defraud the public revenue; and the forging of any marriage register or licence: all which are, by distinct acts of parliament, made felonies without benefit of clergy. By statutes 13 Geo. III. c. 52 and 59, forging or counterfeiting any stamp or mark, to denote the standard of gold and silver plate, and certain other offences of the like tendency, are punished with transportation for fourteen years. By statute 12 Geo. III. c. 48, certain frauds on the stamp duties, therein described, principally by using the same stamps more than once, are made single felony, and liable to transportation for seven years. And the same punishment is inflicted by statute 13 Geo. III. c. 38, on such as counterfeit the common seal of the corporation for manufacturing plate glass (thereby erected), or knowingly demand money of the company by virtue of any writing under such counterfeit seal. There are also two other general laws with regard to forgery; the one 2 Geo. II. c. 25, whereby the first offence in forging or procuring to be forged, acting or assisting therein, or uttering or publishing as true, any forged deed, will, bond, writing obligatory, bill of exchange, promissory note, indorsement, or assignment thereof, or any acquittance or receipt for money or goods, with intention to defraud any person (or corporation), is made felony without benefit of clergy. And by statute 7 Geo. II. c. 22, it is equally penal to forge, or cause to be forged, or utter as true, a counterfeit acceptance of a bill of exchange, or the number of any accountable receipt for any note, bill, or any other security for money, or any warrant or order for the payment of money, or delivery of goods. So that through the number of these general and special provisions, there is now hardly a case possible to be conceived, wherein forgery that tends to defraud, whether in the name of a real or fictitious person, is not made a capital crime.

FORGES, a town of France, in the department of the Lower Seine, famous for its medicinal springs, 60 miles N. W. of Paris.

FORGING, in law, the act of forgery, which see.

FORGING, in smithery, the beating or hammering of iron on the anvil, after having first made it red-hot in the forge, to extend it into various forms, and fashion it into works. See **FORGE**. There are two ways of forging and hammering iron. One is by the force of the hand, in which there are usually several persons employed, one of them turning the iron and hammering likewise, and the rest only hammering. The other is by the force of a water-mill, which raises and works several huge hammers beyond the force of man; under the strokes whereof the workmen present large lumps of iron, which are sustained at one end by the anvils, and at the other by iron chains fastened to the ceiling of the forge. See **MILL**. This last way of forging is only used in the largest works, as anchors for ships, &c. which usually weigh several thousand pounds. For light works, a single man holds, beats, and turns, with one hand, while he hammers with the other. Each purpose the work is designed for requires its proper heat; for if it be too cold, it will not feel the weight of the hammer, as the smiths call it, when it will not batter under the hammer; and if it

be too hot, it will red-sear, that is, break or crack under the hammer. The several degrees of heat the smiths give their iron are, 1. a blood-red heat; 2. a white flame heat; and 3. a sparkling or welding heat.

FORISFAMILIATE, or **FORISFAMILIATION**, in law. When a child, upon receiving a portion from his father, or otherwise, renounces his legal title to any further share of his father's succession, he is said to be forisfamiliarized.

FORK, [*furca*, Lat. *fjorch*, Welsh; *fourche*, Fr.] an instrument divided at the end into two or more points or prongs, used on many occasions.

FORKS, though now indispensable, did not come into use in England till the reign of James I, as we learn from a remarkable passage in Coryat; wherein he describes with no small solemnity, the manner of using them "in all parts of Italy;" and adds, "Hereupon I myself thought good to imitate the Italian fashion by this forked cutting of meat, not only while I was in Italy, but also in Germany, and oftentimes in England since I came home."

FORKS, in geography, the branches of a river, divided and projecting, like the prongs of a fork.

FORLI, a town of Italy, in the province of Romagna, 10 miles S. E. of Faenza, and 45 N. E. of Florence.

FORLI, a fertile and healthy territory of Romagna, of which the above town is the capital.

FORLIMPOPOLI, a town of Italy, in the province of Romagna.

FORLORN-HOPE, in the military art, signifies men detached from several regiments, or otherwise appointed, to make the first attack in day of battle, or at a siege, to storm the counterscarp, mount the breach, &c.

FORM, [*forma*, Lat.] denotes the external appearance or surface of a body, or the disposition of its parts, as to the length, breadth, and thickness.

FORM, in law, the rules established and requisite to be observed in legal proceedings. The formal part of the law, or method of proceeding, cannot be altered but by parliament; for if once these outworks were demolished, there would be an inlet to all manner of innovation in the body of the law itself.

FORM, among mechanics, a sort of mould whereon any thing is fashioned or wrought. Thus, the

1. **FORM, HATTER'S**, is a large block or piece of wood, of a cylindrical figure: the top thereof rounded, and the bottom quite flat. Its use is, to mould or fashion the crown of the hat, after the matter thereof has been beaten and fulled.

2. **FORM, PAPER-MAKER'S**, is the frame or mould wherein the sheets are fashioned. See **PAPER**.

3. **FORM, PRINTER'S**, an assemblage of letters, words, and lines, ranged in order, and so disposed into pages by the compositor; from which, by means of ink and a press, the printed sheets are drawn. Every form is enclosed in an iron chase, wherein it is firmly locked by a number of pieces of wood; some long and narrow, and others like wedges. There are two forms required for every sheet, one for each side; and each form consists of more or fewer pages, according to the size of the book.

FORM, in physics, denotes the manner of being peculiar to each body; or that which constitutes it such a particular body, and distinguishes it from every other. Mr. Harris uses the term form likewise in another sense, as an efficient animating principle; "These animating forms (says he) are of themselves no objects either of the ear or of the eye; but their nature or character is understood in this, that were they never to exert their proper energies on their proper subjects, the marble on which the sculptor exercises his art would remain for ever shapeless, and the harp from which the harper calls forth sounds would remain for ever silent;" that is, in plain language, the former would have no peculiar form and the latter no sound. Then why waste words and render language unintelligible, by such an ambiguous use of the word form? Philosophy, we humbly apprehend, can never be advanced by confounding cause and effect, as Mr. Harris seems to do in the following definition: "The animating form of a natural body is neither its organization nor its figure, nor any other of those inferior forms which make up the system of its visible qualities: but it is the power, which is yet able to produce, preserve, and employ these." If words conveying so very different and opposite ideas, as form and power, are to be thus used synonymously, there will soon be an end of all accuracy in philosophical language.

Philosophers

Philosophers generally allow two principles of bodies : matter, as the common basis or substratum of all ; and form, as that which specifies and distinguishes each ; and which, added to a quantity of common matter, determines or denominates it this or that ; wood, or fire, or ashes, &c. Substantial forms seem to have been first broached by the followers of Aristotle, who thought matter, under different modes or modifications, not sufficient to constitute different bodies ; but that something substantial was necessary to set them at a greater distance : and thus introduced substantial forms, on the footing of souls, which specify and distinguish animals. What led to this erroneous notion was the circumstances of life and death : For observing, that as soon as the soul was departed out of a man, all motion, respiration, nutrition, &c. immediately ceased, they concluded, that all these functions depended on the soul, and consequently that the soul was the form of the animal body, or that which constituted it such : that the soul was a substance, independent of matter, nobody doubted ; and hence the forms of other bodies were concluded equally substantial. But to this it is answered, that though the soul be that by which a man is man, and consequently is the form of the human body, as human ; yet it does not follow, that it is properly the form of this body of ours, as it is a body ; nor of the several parts thereof, considered as distinct from each other : For those several parts have their proper forms so closely connected with their matter, that it remains inseparable therefrom long after the soul has quitted the body : thus, flesh has the form of flesh, bone of bone, &c. long after the soul is removed, as well as before. The truth is, the body does not become incapable of performing its accustomed functions because the soul has deserted it ; but the soul takes its leave, because the body is not in a condition to perform its functions. The ancient and modern corpuscular philosophers, therefore, with the Cartesians, exclude the notion of substantial forms ; and shew, by many arguments, that the form is only the *modus*, or manner of the body it is inherent in. And as there are only three primary modes of matter, viz. figure, rest, and motion, with two others arising therefrom, viz. magnitude and situation, the form of all bodies they hold to consist therein ; and suppose the variations these modes are capable of, sufficient to present all the variety observable in bodies. Forms are usually distinguished into essential and accidental.

1. **FORMS, ACCIDENTAL**, are those really inherent in bodies, but in such a manner as that the body may exist in all its perfection without them. Such is whiteness in a wall, heat in water, a figure of a man in wax, &c.

2. **FORMS, ESSENTIAL**. Though the five modes above mentioned, generally taken, be adventitious ; yet to this or that body, to e.g. fire or water, they are essential : thus, it is accidental to iron, to have this or that magnitude, figure, or situation, since it might exist in different ones : yet to a knife or hammer, the figure, magnitude, and position of parts which constitute it a hammer or knife, are essential ; and they cannot exist or be conceived without them. Hence it is inferred, that though there be no substantial, there are essential, forms, whereby the several species of bodies become what they are, and are distinguished from all others.

FORM OF SYLLOGISMS, or **SYLLOGISTIC FORM**, among logicians, a just disposition both of the terms, in respect of predicate and subject, and of the propositions, in respect of quantity and quality : by which is only meant a disposition wherein the conclusion follows duly and legitimately from the two premises ; there being no form, where there is no conclusion. See **SYLLOGISM**, and **LOGIC**.

FORM, in theology, is said to be one of the essential parts of the sacraments ; being that which gives them their sacramental nature and efficacy, and consisting in certain words, which the priest pronounces in administering them.

FORM is also used, in a moral sense, for the manner of being or doing a thing according to rules : thus we say, a form of government, a form of argument, &c.

FORM, in carpentry, is used to denote the long seats or benches in the choirs of churches or in schools, for the priests, prebends, religious, or scholars, to sit on. At schools, the word form is frequently applied to what is otherwise termed a class.

FORMA, [Lat.] a form or shape. See **FORM**. In the life of St. William of Roschild, *forma* is used for a seat of an ecclesiastic in a choir.

FORMA PAUPERIS, is when a person has just cause of suit, but is so poor that he cannot defray the usual charges of suing at law or in equity ; in which case, on making oath that he is not worth five pounds in the world, on all his debts being paid, and producing a certificate from some lawyer that he has good cause of suit, the judge will admit him to sue in *forma pauperis* ; that is, without paying any fee to counsellors, attorneys, or clerk : the statute 11 Hen. VII. c. 12, having enacted, that counsel and attorneys, &c. shall be assigned to such poor persons gratis. Where it appears that any pauper has sold or contracted for the benefit of his suit, whilst it is depending in court, such cause shall be thenceforth totally dismissed ; and a person suing in *forma pauperis* shall not have a new trial granted him, but is to acquiesce in the judgement of the court.

FORMALITIES, in matter of law, are frequently used for the formulas themselves, or the rules prescribed for judiciary proceedings. In contracts of strict law, all the formalities must be strictly observed ; an omission of the least formality may ruin the whole convention.

FORMALITY, as defined in the schools, is any manner wherein a thing is conceived ; or a manner in any object, importing a relation to the understanding, whereby it may be distinguished from another object. Thus, animality and rationality are formalities.

FORMATION, in grammar, signifies the manner of forming one word from another : thus accountship is formed from accountant, and this last from account.

FORMEDON, in law, (*breve de forma donationis*), a writ that lies for a person who has a right to lands or tenements, by virtue of any entail, arising from the statute of Westm. 2 Ch. II. This writ is of three kinds, viz.

1. **FORMEDON IN DESCENDER** lies where a tenant in tail in feoff a stranger, or is disseised and dies, and the heir may bring this writ to recover the lands.

2. **FORMEDON IN REMAINDER** lies where a man gives lands, &c. to a person in tail, and, for default of issue of his body, the remainder to another in tail : here if the tenant in tail die without issue, and a stranger abates and enters into the land, he in remainder shall have this writ.

3. **FORMEDON IN REVERTER** lies where lands are entailed on certain persons and their issue, with remainder over for want of issue ; and, on that remainder failing, then to revert to the donor and his heirs : in this case, if the tenant in tail dies without issue, and also he in remainder, the donor and his heirs, to whom the reversion returns, may have this writ for the recovery of the estate, though the same be alienated, &c.

FORMERIE, a town of France, in the department of Oise, 9 miles W. of Grandvilliers.

FORMIA, or **FORMIE**, in ancient geography, a maritime town of the Adjected, or New Latium, on the S. E. of Cajeta ; now in ruins, near Mola.

FORMIANI, the people of Formia, who were admitted to the liberty of the city the very year in which Alexandria was built ; but not to the right of suffrage till long after the second Punic war.

FORMIC ACID. It has long been known that ants contain a strong acid, which they occasionally emit ; and which may be obtained from the ants either by simple distillation or by infusion of them in boiling water and subsequent distillation of as much of the water as can be brought over without burning the residue. This has now lost its rank as a separate acid, and it has been shewn by Fourcroy and Vauquelin to be a compound of the malic and acetic.

FORMICA, in natural history, the **ANT** or **EMMET**, a genus of insects of the order hymenoptera. Feelers four, unequal, with cylindrical articulations, placed at the tip of the lip, which is cylindrical and nearly membranaceous ; antennæ filiform ; a small erect scale between the thorax and abdomen ; females and neuters armed with a concealed sting ; males and females with wings, but neuters have no wings. According to Linnæus there are eighteen species. The insects of this genus live in large societies, somewhat in the manner of bees and wasps, and are like them divided into males, females, and neutrals, which latter constitute the great or general assortment, and appear to conduct the business of the nest, which is usually placed at a small distance from the surface in some slight elevation either prepared by the insects themselves,

or previously formed by some other animals, as moles, &c. They feed both on animal and vegetable substances, devouring the smaller kind of insects, caterpillars, &c. as well as fruits of different kinds. They are particularly attracted by sweets; and for this reason they ascend such trees as are infested with aphides, in order to obtain the saccharine substance discharged by those animals; and hence seems to have arisen the idea of their enmity against the genus aphid. Some species of ants are furnished with a sting, while others are destitute of that part. The largest of the European ants is the formica herculeana, or great wood-ant, of a chesnut-colour, with the abdomen measuring two lines or more in length. This species is chiefly found in dry woods of pine or fir, where it inhabits a large conical nest or hillock, composed of dry vegetable fragments, chiefly of fir-leaves: the nest is internally distributed into several paths or tubes, converging towards the central part, and opening externally: in the middle or centre reside the young, or larvæ, which are nursed by the neutral ants, and are occasionally brought to the surface, in order to be more within the influence of the air and sunshine for a certain time, after which they are again conveyed to the bottom or centre. When full-grown, they envelop themselves in oval, white, silken cases, in which they undergo their change into chrysalis, and at length emerge in their complete form. The males and females are winged, and the females are much larger than the males. The common or black ant, formica nigra Lin. is a well-known inhabitant of our fields and gardens, residing in great numbers beneath mole-hills and other elevated spots. It is of a brownish-black colour, and of a glossy or polished surface. Ants are very industrious in collecting and laying up hoards of wheat and other corn; and lest the corn should sprout by the moisture of the subterraneous cells, they gnaw off the end which would produce the blade. The ants are often seen pushing along grains of wheat or barley much larger than themselves. The stores thus obtained are for their evening repasts, and for their support during a rainy season, &c. About the beginning of August the males and females may be observed in the nests: these differ from the neutrals in being furnished with wings, and the female is far larger than the male, the body equalling in size that of the common window-fly, and the upper wings being very long and large. At this time of the year the males and females emigrate in vast numbers; sometimes flying at a considerable height, and sometimes creeping along the surface. It is not uncommon to see them enter houses at this period, attracted by sweets in particular, either moist or dry. After the breeding season the males live but a very short time, and the females return to their nests in order to deposit their eggs. During the winter this species, like the rest of the European ants, remains in a state of torpor, without laying up provisions for that season, as erroneously supposed; and during the spring emerges from its concealment, and recommences its labours. Ants feed both on animal and vegetable substances of various kinds. Their fondness for animal substances is often turned to good account by anatomists, who, when they wish to obtain the skeleton of any animal too small or delicate to admit of being prepared the usual way, dispose the animal in a proper position in a small box, with perforations in the lid, and deposit it in a large ant-hill; in consequence of which, after a certain space, the whole of the softer parts are eaten away by these insects, and the skeleton remains in its proper position. It is thus that very elegant skeletons of frogs, snakes, &c. may be obtained. The formica rufa is black; thorax compressed; and with legs ferruginous. See Plate LXXXVI.

FORMING A SIEGE, is the making lines of circumvallation to fortify the camp, and disposing things for the attack of a place in form.

FORMING A SQUADRON OR BATTALION is to range the soldiers in form of a squadron, &c.

FORMING THE LINE, is drawing up infantry, cavalry, and artillery, into line of battle.

FORMOSA, an island of the Pacific Ocean, about 100 miles E. of Canton in China, separated from the province of Fokien by a strait about 60 miles broad. It is subject to the Chinese; who, however knew not of its existence until 1430. It is about 85 leagues long, and 25 broad. This island presents extensive and fertile plains, watered by great number of rivulets that fall from the eastern mountains. The air is pure and wholesome, and the soil produces in abundance corn and rice, with most other grains, and Indian fruits; such as oranges, bananas, pine-apples, guavas, pa-

paws, cocoa-nuts; as well as many of Europe. Tobacco, sugar, pepper, camphire, and cinnamon, are also common. Horses, sheep, goats, and hogs, are very rare in this island. Domestic fowls, geese, and ducks, are in great plenty; pheasants also are sometimes seen; but monkeys and stags have multiplied so much, that they wander through the country in large flocks. The inhabitants rear a great number of oxen, which they use for riding, from a want of horses and mules. Formosa lies between 119° and 122° Lon. E. and between 22° 5' and 25° 28' Lat. N.

FORMOSA, an island in the Atlantic, near the coast of Africa, about 6 miles long, and 3 broad. The soil is fertile and covered with trees, but the island is deficient in good water. Lon. 14. 20. W. Lat. 11. 29. N.

FORMULA, or **FORMULARY**, a rule or model, or certain terms prescribed or decreed by authority, for the form and manner of an act, instrument, proceeding, or the like.

FORMULA, in church history and theology, signifies a profession of faith.

FORMULA, in medicine, imports the constitution of medicines, either simple or compound, both with respect to their prescription and consistence.

FORMULA, a theorem or general rule or expression for resolving certain particular cases of some problem, &c. So $\frac{s}{2} + \frac{d}{2}$

is a general formula for the greater of two quantities whose sum is

s and difference d ; and $\frac{s}{2} - \frac{d}{2}$ is the formula, or general value

for the less quantity. Again $\sqrt{ax - x^2}$ is the formula or general value of the ordinate to a circle, whose diameter is d , and absciss x .

FORNACALIA, or **FORNICALIA**, in Roman antiquity, a festival instituted by Numa, in honour of the goddess Fornax; wherein certain cakes were made, and offered in sacrifice before the ovens.

FORNAX, the goddess of ovens.

FORNICATION, [*fornicatio*, Lat. from the fornices in Rome, where the lewd women prostituted themselves for money.] Formerly court-leets had power to inquire of and punish fornication and adultery; in which courts the king had a fine assessed on the offenders, as appears by the book of Domesday. In 1650, not only incest and wilful adultery were made capital crimes, but also the repeated act of keeping a brothel, or committing fornication, was (upon a second conviction) made felony without benefit of clergy. But at the restoration, it was not thought proper to renew a law of such unfashionable rigour. And these offences have been ever since left to the feeble coercion of a spiritual court, according to the rules of the canon law; a law which has treated the offence of incontinence, nay, even adultery itself, with a great degree of tenderness and lenity; owing perhaps to the constrained celibacy of its first compilers. The temporal courts therefore take no cognizance even of the crime of adultery, otherwise than as a private injury. See **ADULTERY**. The evils of fornication, which too many wish to consider as no sin, may be judged of from the following particulars: 1. The malignity and moral quality of each crime is not to be estimated by the particular effect of one offence, or of one person's offending, but by the general tendency and consequence of crimes of the same nature. Let the libertine consider, what would be the consequence, if the same licentiousness in which he indulges were universal? or what should hinder its becoming universal, if it be innocent or allowable in him? 2. Fornication supposes prostitution; and by prostitution the victims of it are brought to almost certain misery. It is no small quantity of misery in the aggregate, which between want, disease, and insult, is suffered by those outcasts of human society who infest populous cities; the whole of which is a general consequence of fornication, and to the increase and continuance of which every act and instance of fornication contributes. 3. Fornication produces habits of ungovernable lewdness, which introduce the more aggravated crimes of seduction, adultery, violation, &c. The criminal indulgences between the sexes prepare an easy admission for every sin that seeks it: they are, in low life, usually the first stage in men's progress to the most desperate villanies; and in high life, to that lamented dissoluteness of principle, which manifests

manifests itself in a profligacy of public conduct, and a contempt of the obligations of religion and moral probity. 4. Fornication perpetuates a disease, which may be accounted one of the sorest maladies of human nature, and the effects of which are said to visit the constitutions of even distant generations. The passion being natural, proves that it was intended to be gratified; but under what restrictions, or whether without any, must be collected from different considerations. In the Scriptures, fornication is absolutely and peremptorily condemned. 'Out of the heart proceedeth evil thoughts, murders, adulteries, fornications, &c. these are the things which defile a man.' These are Christ's own words; and one word from him upon the subject is final. The apostles are more full upon this topic. One well-known passage in the Epistle to the Hebrews may suffice, because, admitting the authority by which the apostles wrote, it is decisive. 'Marriage and the bed undefiled is honourable amongst all men, but whoremongers and adulterers God will judge;' which was a great deal to say, at a time when it was not agreed even amongst philosophers that fornication was a crime. Mr. Paley adds the following just observations, in his "Moral and Political Philosophy," p. 246. "The Scriptures give no sanction to those austerities which have been since imposed upon the world under the name of Christ's religion, as the celibacy of the clergy, the praise of perpetual virginity, the prohibito concubitus cum gravida uxore; but with a just knowledge of, and regard to, the condition and interest of the human species, have provided in the marriage of one man with one woman an adequate gratification for the propensities of their nature, and have restrained them to that gratification. The avowed toleration, and in some countries the licensing, taxing, and regulating, of public brothels, has appeared to the people, an authorizing of fornication, and has contributed, with other causes, so far to vitiate the public opinion, that there is no practice of which the immorality is so little thought of, or acknowledged, although there are few in which it can more plainly be made out. The legislators who have patronized receptacles of prostitution ought to have foreseen this effect, as well as considered, that whatever facilitates fornication, diminishes marriages. And as to the usual apology for this relaxed discipline, the danger of greater enormities if access to prostitutes were too strictly watched and prohibited; it will be time enough to look to that, after the laws and the magistrates have done their utmost. The greatest vigilance of both will do no more, than oppose some bounds and some difficulties to this intercourse. And after all, these pretended fears are without foundation in experience. The men are in all respects the most virtuous in countries where the women are most chaste. If fornication be criminal, all those incentives which lead to it are accessaries to the crime; as lascivious conversation, whether expressed in obscene, or disguised under modest phrases; also wanton songs, pictures, books; the writing, publishing, and circulation of which, whether out of frolic or for some pitiful profit, is productive of so extensive a mischief from so mean a temptation, that few crimes within the reach of private wickedness have more to answer for, or less to plead in their excuse. Indecent conversation, and by parity of reason all the rest, are forbidden by St. Paul, Eph. iv. 29, 'Let no corrupt communication proceed out of your mouth;' and again, Col. iii. 8, 'Put filthy communications out of your mouth.' The invitation or voluntary admission of impure thoughts, or the suffering them to get possession of the imagination, falls within the same description, and is condemned by Christ, Matt. v. 28, 'Whosoever looketh on a woman to lust after her, hath committed adultery with her already in his heart.' Christ, by thus enjoining a regulation of the thought, strikes at the root of the evil."

FORNIX, in anatomy, part of the corpus callosum in the brain; so called, because of a distant resemblance it hath to the arches of ancient vaults when viewed in a particular manner.

FORSKOHLEA, in botany, a genus of the pentagynia order, and decandria class. Calyx four or five-leaved, longer than the corolla; petals ten, roundish before, with a linear base. There are three species.

FORSTER, JOHN REINHOLD, a celebrated naturalist, was born in Prussia in 1729. He made, when young, a great progress in the learned and modern languages. In 1748 he entered the university of Halle, where he studied divinity: from thence he removed to Dantzic, and commenced preacher. He afterwards

went to Russia, in expectation of considerable preferment; but being disappointed, he proceeded to England, where for some time he was tutor in the French and German languages at Warrington. In 1772 he accompanied Captain Cook on his voyage round the World. He returned to England in 1775, and was honoured by the university of Oxford with the degree of LL. D. Having published, contrary to the engagement entered into with government, a botanical account of plants discovered in this voyage, he was treated with such coolness, that he quitted England and went to Halle, where he was made professor of natural history. He died in 1798. He was the author of Observations made in a Voyage round the World; History of Voyages and Discoveries in the North; on the Byssus of the Ancients; several Papers in the Philosophical Transactions, &c.

FORSTA, a town of Lusatia, on the Neiss, 54 miles N. N. E. of Dresden.

FORSTERA, in botany, a genus of the diandria order, and gynandria class of plants. Perianthium double; exterior one beneath, three-leaved; interior one above, six-cleft; corolla tubular.

FORSTER'S HARBOUR, a bay in Hudson's Strait, Hudson's Bay. Lon. 73. 30. W. Lat. 62. 18. N.

FORT, in the military art, a small fortified place, environed on all sides with a moat, rampart, and parapet. Its use is to secure some high ground, or the passage of a river, to make good an advantageous post, to defend the lines and quarters of a siege, &c. Forts are made of different figures and extents, according as the ground requires. Some are fortified with bastions, others with demi-bastions. Some again are in form of a square, others of a pentagon. A fort differs from a citadel, as this last is built to command some town.

FORTALICE, in Scots law, signified anciently a small place of strength, originally built for the defence of the country; and which on that account was formerly reckoned inter regalia, and did not go along with the lands upon which it was situated, without a special grant from the crown. Now, fortalices are carried by a general grant of the lands; and the word is become synonymous with manor-place, messuage, &c.

FORTESCUE, Sir JOHN, lord high chancellor of England, under Henry VI. was descended from an ancient family in Devonshire. He studied the municipal law in Lincoln's Inn, of which he was made a governor, in the fourth and seventh years of Henry VI. In 1430, he was made a serjeant at law, and, in 1441, king's serjeant. In 1442 he was made lord chief justice of the king's bench; and afterwards lord high chancellor. During the reign of Edward IV. he was many years in exile with Queen Margaret and Prince Edward her son. When they returned to England, Sir John Fortescue accompanied them, but soon after the decisive battle of Tewksbury, he was thrown into prison and attainted, with other Lancastrians; but was pardoned by Edward IV. He wrote, 1. A Commentary on the Politic Laws of England; to one edition of which Mr. Selden wrote notes. 2. The difference between an absolute and a limited Monarchy, as it more particularly regards the English Constitution (which was published, with some remarks, by John Fortescue, afterwards Lord Fortescue, in 8vo. in 1714; and a second edition was published, with amendments, in 1719;) and several works which still remain in MS. He died, near 90 years of age, and was buried in the parish-church of Ebburton, where a monument was erected to his memory in 1677.

FORTH, in geography, one of the finest rivers in Scotland. It takes its rise near the bottom of Lomond hills; and running from W. to E. receives in its passage many considerable streams, deriving their waters from the eminences in the midland counties of North Britain. Below Alloa the river expands itself to a great breadth between the counties of Lothian and Fife, till at Queensberry it is contracted by promontories shooting into it from both coasts; so that, from being four or five miles broad, it is not above two miles.

FORTH AND CLYDE NAVIGATION. By these rivers, Scotland is almost divided into two parts. The Forth falls into the E. sea below Edinburgh, and the Clyde falls into the Atlantic Ocean, below Glasgow, and the neck of land between them amounting scarcely to 24 miles, gave rise to the idea of a junction, so as to open a communication across the kingdom, an object of vast utility; and which was at last happily completed, on the 28th July, 1790.

FORTIFICATION.

FORTIFICATION, may be defined the science of military architecture; and when applied to a city, town, or other place, it consists in the art of putting any of these in such a posture of preparation by means of ramparts, parapets, ditches, and outworks, that each individual part defends, and is defended by; some other parts, so that a small number of men within may be able to defend themselves, for a considerable time, against the assaults of a numerous army without. The origin of fortification is doubtless to be ascribed to that rapacious principle, which has influenced too many of mankind in all ages and nations, to invade the rights and properties of those whom they considered as weak or defenceless. In the first ages of the world, men were dispersed over the earth in separate families, as is recorded in the patriarchal histories of the Jews and Scythians, who wandered from place to place, in search of pasture for their cattle. These families became so numerous as to form large communities, which settled all together in one place; from whence villages and towns had their origin: but they found it necessary, for the common security, to surround those towns with walls and ditches, to prevent all violences and sudden surprises from their neighbours. This was sufficient for some time, till offensive weapons were invented, and conquering became a fashion. Then walls with loop-holes were made at proper distances, in order to screen the defenders against the arrows of the assailants: but finding that, as soon as the enemy got once close to the walls, they could from no part be discovered or repulsed; for this reason they added square towers at proper distances from each other, so that every part of the wall might be defended by the adjacent sides of the towers. However, this manner of the inclosing of towns was found to be imperfect, because there remained still one of the faces of the towers which fronted the field that could not be seen from any other part, and therefore could not be defended. To remedy this, they made the towers round instead of square, imagining this figure to be the strongest to resist the battering engines, as well as to be better defended from the other parts of the wall. Notwithstanding the superiority of this method above the former, there still remained a part of these towers unseen and incapable of being defended; which made them change the figure of the towers again; *i. e.* they made them square as before; but, instead of presenting a face to the field as formerly, they presented an angle; and thus they effectually found out such a disposition of their works, that no part could be attacked without being seen or defended from some other part. This last method was long in use, and would in all probability have continued to this day, if gun-powder had not been invented: but the violence of the guns and mortars soon convinced the world, that such towers and walls were but a weak defence against these thundering engines; and that, as the nature of the attack was entirely changed, it was also necessary to change the mode of defence. Ramparts were therefore added to the walls; the towers enlarged into bastions, and all sorts of outworks have been since added; such as ravelins, counterguards, horn and crown works, and others of the like nature, to render the defence in some measure equivalent to the attack. But in spite of all the improvements which have been made in the art of fortifying, since the invention of gunpowder, that of attacking is still superior to it: engineers have tried in vain to render the advantages of fortification equal to those of the attack; the superiority of the besiegers' fire, together with the greater number of men, generally obliges the besieged to submit sooner or later. The greatest improvement made in the art of attacking happened in 1697, when M. Vauban first made use of ricochet firing at the siege of Ath, whereby the besieged placed behind the parapets were as much exposed to the fire of the besiegers as if there had been no parapets; whereas, before, they had been secure as long as the parapet was not demolished: and the worst is, that there can be no remedy found to prevent this enfilading; without falling into inconveniences almost as bad as those which we endeavour to avoid.

Definitions. 1. In the plan and profile, Plate LXXIII. fig. 1, the part N C D E F represents a bank of earth called the parapet, its use is to cover the troops from the fire of the enemy. 2. The part D E is called the talus or plunge, and is a little sloping toward the further side; it does not rise perpendicularly but slopes on each side as represented by C D and E F. 3. When the height of the parapet exceeds $4\frac{1}{2}$ feet which is generally the case, a part A B C is raised to elevate the men sufficiently to fire over the parapet; this is called the banquette or foot-bank, it rises to the flat part B C by a gentle slope A B; sometimes there are two banquettes. 4. H I represents the ditch behind the parapet, having the slope G H, towards the parapet, called the scarp, and I K on the opposite side called the counterscarp. 5. The flat part F G is called berme, and serves to lodge the loose earth that may fall from the parapet. 6. K L represents the glacis, which is generally in a line with the talus D E. 7. In Plate LXXIV. fig. 1, the part F E A L N is called the bastion. 8. A E, A L, the faces of the bastion. 9. E F, L N, the flanks. 10. F G, the curtain. 11. F N, the gorge of the bastion. 12. A G, B F, the lines of defence. 13. A B, the exterior side of the polygon. 14. C D, the perpendicular. 15. Any line which divides a work into two equal parts is called the capital of that work. 16. *a, b, c*, the counterscarp of the ditch. 17. A, M, the flanked angles. 18. H, E, L, the angles of the shoulder, or shoulder only. 19. G, F, N, the angles of the flank. 20. Any angle whose point turns from the place is called salient angle, such as A, M: and any angle whose point turns towards the place, re-entering angle, such as *b, F, N*. 21. If there be drawn two lines parallel to the principal or outline, the one at three toises distance, and the other at eight from it, then the space *y x* included between the principal one and that farthest distant is called the rampart. And the space *x*, contained by the principal line and that near to it, and which is generally stained black, is called the parapet. There is a fine line drawn within four feet of the parapet, which expresses the step called banquette. All works have a parapet of three toises thick, and a rampart of from 8 to 10, besides their slopes. The rampart is elevated more or less above the level of the place, from 10 to 20 feet, according to the nature of the ground, and the particular constructions of engineers. 22. The body of the place is all that which is contained within this first rampart; for which reason it is often said to construct the body of the place: which means, properly, the construction of the bastions and curtains. 23. All the works which are constructed beyond the ditch, before the body of the place, are called outworks.

GENERAL PRINCIPLES, OR MAXIMS.

1. The plan of every place that is to be fortified, ought first to be circumscribed with one of the most convenient polygonal figures, that can be fitted to that place, and this polygon is to be fortified.
2. The more regular the circumscribing polygon is, the better.
3. It is a disadvantage, to be necessitated to extend the works about a fortress.
4. Every side of the polygon, as much as is possible, should be equally fortified, that the enemy may not have it in his choice to attack a part more weak than the rest.
5. All works ought as much as possible to be easy to build, hard to destroy, and not difficult to be repaired.
6. The works about a fortress should be so contrived, as to cover the defendants, discover the approaches to the enemy, and adapted to the common weapons of defence.
7. Each work should be defended from as many as may be and liable to be attacked from as few places as possible.
8. These works, made to defend one another, should be sufficiently large to contain the troops and cannon necessary for that defence.
9. Works which are to flank one another ought not to be at a greater distance than the point bank flight of a musket-shot.
10. The works farthest distant from the body of the place should

should be lowest, that they may be commanded by those that are nearer.

11. None of the works should, if it can be helped, be beyond the point bank reach of the cannon within the town.

12. Wet ditches are preferable for small places, dry ones for large places.

13. Bastions with large flanks and large gorges are much esteemed.

14. The flanked angles of bastions should not be much less than a right one, but are better when obtuse not exceeding 120 or 130 degrees.

15. The faces of bastions should in length not differ much from 100 yards.

16. A curtain should not be much longer than 180 yards, nor much shorter than 100 yards.

17. The angle of the curtain should be between the limits of 90 and 100 degrees.

The art of fortification is divided into two parts; regular and irregular.

OF REGULAR FORTIFICATION.

Regular Fortification is that built in a regular polygon, the sides and angles of which are all equal, being commonly about a musket-shot from each other. Although authors agree as to the general form in the present manner of fortifying, yet they mostly differ in particular constructions of the parts. As it would be superfluous to treat of all the different methods hitherto proposed, we shall explain those only which are most esteemed by the best judges, and have been most generally practised.

CONSTRUCTION OF THE MEAN FORTIFICATION, ACCORDING TO M. VAUBAN'S METHOD.

Vauban's method is divided into little, mean, and great; the

little is chiefly used in the construction of citadels, the mean in that of all sorts of towns, and the great in particular cases only. We shall give the construction of the mean, as being most useful; and refer the reader to the following table, for those dimensions which are different in these several fortifications. Inscribe in a circle a polygon of as many sides as the fortification is designed to have fronts; let AB, fig. 1. Plate LXXIV, be one of the sides of half a hexagon, which bisect by the perpendicular CD; divide half of it AC into nine equal parts, and one of these into 10 others; then these divisions will serve as a scale to construct all the parts of the fortification, and each of them is supposed to be a toise or fathom, that is, six French feet, or somewhat more than $5\frac{1}{2}$ English feet; and therefore the whole side AB is supposed to be 180 toises. As the dividing of a line into so many equal parts is very troublesome, it is much easier to have a scale of equal parts by which the works may be constructed. If therefore, in this case, the radius is taken equal to 180 toises, and the circle described with that radius being divided into six equal parts, or the radius being carried six times round, we will have an hexagon inscribed; AB being bisected by the perpendicular CD, as before, set off 30 toises from C to D, and draw the indefinite lines ADG, BDF; in which take the parts AE, BH, each equal to 50 toises; from the centre E describe an arc through the point H, meeting AD in G, and from the centre H describe an arc through the point E, meeting BD in F; or which is the same, make each of the lines EG, HF, equal to the distance EH; then the lines joining the points A, E, F, G, H, B, will be the principal or outline of the front. If the same construction be performed on the other sides of the polygon, we will have the principal or outline of the whole fortification. If, with a radius of 20 toises, there be described circular arcs, from the angular points B, A, M, T, and lines are drawn from the opposite angles, E, H, &c. so as to touch these arcs, their parts *a, b, c*, &c. together with these arcs, will represent the outline of the ditch.

TABLE OF DIMENSIONS.

	Forts.						Little Fortification.				Mean.		Great.	
Sides of Polygons,.....	80	90	100	110	120	130	140	150	160	170	180	190	200	260
Perpendiculars,.....	10	11	12 $\frac{1}{2}$	14	15	16	20	21	23	25	30	31	25	22
Faces of Bastions,.....	22	25	28	30	33	35	40	42	45	47	50	35	55	60
Capital of Ravelin,.....	25	28	30	35	38	40	45	50	50	52	55	55	60	50

In the first vertical column are the numbers expressing the lengths of the exterior sides from 80 to 260. In the second, the perpendiculars answering to these sides. In the third, the lengths of the faces of bastions; and in the fourth, the lengths of the capitals of the ravelins. The forts are mostly, if not always, squares: for which reason, the perpendiculars are made one-eighth of the exterior sides; because if they were more, the gorges of the bastions would become too narrow. The little fortification is chiefly designed for citadels, which are commonly pentagons; the perpendiculars are made one-seventh of the exterior side: the mean is used in all kinds of fortifications, from an hexagon upwards to any number of sides; and the great is seldom used but in an irregular fortification, where there are some sides that cannot be made less without much expence; or in a town which lies near a great river, where the side next the river is made from 200 to 260 toises: and as that side is less exposed to be attacked than any other, the perpendicular is made shorter, which saves much expence. The faces of the bastions are all two-sevenths of the exterior sides, or nearly so, because the fractions are neglected. In general, in all squares the perpendicular is one-eighth of the exterior side, and all pentagons one-seventh, and in all the rest upward one-sixth.

OF THE CONSTRUCTION OF ORILLONS AND RETIRED FLANKS.

Describe the front MPQRST as before, and divide the flank into three equal parts, of which suppose *Sr* to be one; from the opposite flanked angle *M* draw a line *Mr*, in which take the part *mr* of five toises; take likewise *Rn* in the line of defence *MR*,

produced, equal to five toises, and join *nm*, upon which as a base describe the equilateral triangle *n p m*, and from the angle *p*, opposite to the base as centre, is described the circular flank *n m*. And if *Sr* be bisected by a perpendicular, and another be erected upon the face *ST*, at *S*; the intersection of these two perpendiculars will be the centre of the arc which forms the orillon. The orillons are very useful in covering the retired flanks, which cannot be seen but directly in the front; and as these orillons are round, they cannot be so easily destroyed as they would be if they were of any other figure.

CONSTRUCTION OF RAVELINS OR HALF-MOONS.

Fig. 1. No. 1. Set off 55 toises, from the re-entering angle *O* of the counterscarp, on the capital *OL*, or on the perpendicular produced; and from the point *L* draw lines to the shoulders *AB*; whose parts *LM*, *LN*, terminated by the counterscarp, will be the faces, and *MO*, *ON*, the semi-gorges of the ravelin required. This is Mr. Vauban's method of constructing ravelins, according to some authors: and others will have the faces of the ravelin to terminate on those of the bastions within three toises of the shoulders; which seems to be the best way, for these ravelins cover the flanks much better than the others. The ditch before the ravelin is 12 toises, its counterscarp parallel to the faces of the ravelins; and is made in a circular arc, before the salient angle; as likewise all ditches are in general. When the ravelins are made with flanks, as in fig. 2, the faces should terminate on those of the bastions, at least five toises from the shoulders. The flanks are made by setting off 10 toises from the extremities of the faces, from *f* to *h*, and from

from *m* to *l*; and from the points *h*, *l*, the flanks *hk*, *lp*, are drawn parallel to the capital LO of the ravelin. There are sometimes redoubts made in the ravelin, such as in fig. 1. No. 1. which is done by setting off 16 toises from the extremities of the faces on the semi-gorges from *N* to *b*, and from *M* to *a*; and from the points *b*, *a*, the faces are drawn parallel to those of the ravelin; the ditch before the redoubt is six toises, and its counterscarp parallel to the faces.

CONSTRUCTION OF TENAILLES.

A *tenaille* is a work made in the ditch before the curtains, the parapet is only two or three feet higher than the level ground of the ravelin. There are three different sorts; the first are those, as in fig. 3, which are made in the direction of the lines of defence, leaving a passage of three toises between their extremities and the flanks of the bastions, as likewise another of two in the middle for a bridge of communication to the ravelin. The second sort are those, as in fig. 4. Their faces are in the lines of defence, and 16 toises long, besides the passage of three toises between them and the flanks of the bastion; their flanks are found by describing arcs from one shoulder of the *tenaille* as centre through the other, or on which are set 10 toises for the flanks desired. The third sort are those as in fig. 5. Their faces are 16 toises, as in the second sort, and the flanks are parallel to those of the bastions. The use of *tenailles* in general, is to defend the bottom of the ditch by a grazing fire, as likewise the level ground of the ravelin, and especially the ditch before the redoubt within the ravelin, which can be defended from no where else so well, as from them. The first sort do not defend the ditch so well, as the others, as being too oblique a defence; but as they are not subject to be enfiladed, M. Vauban has generally preferred them in the fortifying of places, as may be seen in the citadel of Lille, Landau, New Brisac, and in many other places. The second sort defend the ditch much better than the first, and add a low flank to those of the bastions; but as these flanks are liable to be enfiladed, they have not been much put in practice. This defect might however be remedied, by making them so as to be covered by the extremities of the parapets of the opposite ravelins, or by some other work. As to the third sort, they have the same advantage as the second, and are likewise liable to the same objections; for which reason, they may be used with the same precautions which have been mentioned in the second. *Tenailles* are esteemed so necessary, that there is hardly a place fortified without them; and with reason: For when the ditch is dry, the part behind the *tenailles* serves as a place of arms, from which the troops may sally, and destroy the works of the enemy and the ditch, oppose their descent, and retire with safety; and the communication from the body of the place to the ravelin becomes easy and secure, which is a great advantage; for by that means the ravelin may be a much better defence, as it can be supplied with troops and necessaries at any time. And if the ditch is wet, they serve as harbours for boats, which may carry out armed men to oppose the passage over the ditch whenever they please; and the communication from the *tenailles* to the ravelin, becomes likewise much easier than it would be without them.

CONSTRUCTION OF LUNETTES.

Fig. 1. No. 2. Lunettes are placed on both sides of the ravelin, such as B, to increase the strength of a place: they are constructed, by bisecting the faces of the ravelin with the perpendicular LN; on which is set off 30 toises from the counterscarp of the ditch, for one of its faces; the other face, PN, is found by making the semigorge, TP, of 25 toises; the ditch before the lunette is 12 toises, the parapet three, and the rampart eight, as in the ravelin. There is sometimes another work made to cover the salient angle of the ravelin, such as A, called *bonnet*, whose faces are parallel to those of the ravelin, and when produced, bisect those of the lunettes; the ditch before is 10 toises. There are likewise lunettes, such as D in fig. 6, whose faces are drawn perpendicular to those of the ravelin, within a third part from the salient angle; and their semi-gorges are only 20 toises. These kinds of works may make a good defence, and cost no very great expence; for as they are so near the ravelin, the communication with it is very easy, and one cannot well be maintained till they are all three taken.

CONSTRUCTION OF TENAILLONS.

Fig. 1. No. 3. Produce the faces of the ravelin beyond the

counterscarp of the ditch, at a distance MN of 30 toises, and take on the counterscarp of the great ditch 15 toises from the re-entering angle *q* to *p*, and draw Np; then pNMq will be the *tenailles* required; its ditch is 12 toises, that is, the same as that of the ravelin. Sometimes a retired battery is made in the front of the *tenailles*, as in B; this battery is 10 toises from the front to which it is parallel, and 15 toises long. Retrenchments are commonly made in the *tenailles*, such as O; their parapets are parallel to the fronts MN, and bisect the side pN; the ditch before the retrenchment is three toises; and there is a banquette before the parapet next to the ditch of about eight feet, called *berin*; which serves to prevent the earth of the parapet (which seldom has any revetment) from falling into the ditch. The ravelin, before which *tenailles* are constructed, must have its salient angle much greater than the former construction makes them; otherwise the salient angles of the *tenailles* become too acute; for which reason we made the capital of this ravelin 45 toises, and the faces terminate within three toises of the shoulders.

CONSTRUCTION OF COUNTER-GUARDS.

When the counterguard is placed before the ravelin, fig. 7, set off 40 toises on the capital of the ravelin from the salient angle A to the salient angle B, of the counterguard; and 10 from C to D; on the counterscarp of the ditch. When the counterguard is before the bastion, such as in fig. 8, its salient angle F is 50 toises from the salient angle E of the bastion, and the breadth near the ditch of the ravelin 10 toises as before. The ditch before the counterguards is 12 toises, and its counterscarp parallel to the faces. Counterguards are made before the ravelin on some particular occasions only; but are frequently constructed before the bastions, as covering the flanks wonderfully well. Some authors, as Mr. Blondel and Mr. Coehorn, will have them much narrower than they are here.

CONSTRUCTION OF HORN-WORKS.

Fig. 1. No. 4. Produce the capital of the ravelin beyond the salient angle A, at a distance AB of about 80 toises; draw DBE at right angles to AB; in which take BD, BE, each equal to 55 toises; and on the exterior side DE, trace a front of a polygon in the same manner as that of the body of the place, making the perpendicular BF 10 toises, and the faces 30. The branches Da, Ed, of the horn-work, when produced, terminate on the faces of the bastions, within five toises of the shoulders. The ditch of the horn-work is 12 toises, and its counterscarp parallel to the branches; and in the front terminates at the shoulders, in the same manner as the great ditch before the bastions. The capital of the ravelin before the front of the horn-work is 35 toises, and the faces terminate on the shoulders, or rather two or three toises beyond them: and the ditch before the ravelin is eight toises. Retrenchments are sometimes made within the horn-works, such as S, S; which are constructed by erecting perpendiculars to the faces of the ravelins, within 25 toises of their extremities. This retrenchment, like all others, has a parapet turfed only with a berm of eight feet before it; as likewise a ditch from three to five toises broad. When a horn-work is made before the bastion, the distance, No. 5, of the front from the salient angle of the bastion is 100 toises, and the branches terminate on the faces of the adjacent ravelins within five toises from their extremities; all the rest is the same as before.

CONSTRUCTION OF CROWN-WORKS.

From the salient angle, A, fig. 9, of the ravelin, as a centre, describe an arc of a circle with a radius of about 120 toises, cutting the capital of the ravelin produced at C; from the point C, set off the chords CB, CF, each of them equal to 110 toises; and on each of which, as an exterior side, construct a front of polygon of the same dimensions as in the horn-work; that is, the perpendicular should be 18 toises, the faces 30, and the branches terminate on the faces of the bastions within 25 toises of the shoulders. The ditch is 12 toises, the capital of the ravelins 35, and its ditch 8; that is, the same as in the horn-work. Sometimes the crown-work is made before the bastion, as in fig. 10. The arc is described from the salient angle A of the bastion, with a radius of 120 toises, as before; and the branches terminate on the faces of the adjacent ravelins within 25 toises of their extremities: the rest of the dimensions and constructions are the same as before. Horn-works, as well as crown-works, are never made but when a large spot of ground

ground falls beyond the fortification, which might be advantageous to an enemy in a siege, or to cover some gate or entrance into a town.

CONSTRUCTION OF COVERT-WAYS AND GLACIS.

Although we have not hitherto mentioned the covert-way, nevertheless all fortifications whatsoever have one; for they are esteemed to be one of the most essential parts of a modern fortification; and it is certain, the taking of the covert-way, when it is in good condition and well defended, is generally the most bloody action of the siege. After having constructed the body of the place, and all the outworks which are thought necessary, lines are drawn parallel to the utmost counterscarp of the ditches, at six toises distance from it; and the space mn , $m n$, Plate LXXV, fig. 1, included between that line and the counterscarp, will be the covert-way required. There is in every re-entering angle of the counterscarp a place of arms, m : which is found by setting off 20 toises from the re-entering angle a , on both sides from a to b , and from a to c ; and from the points b, c , as centres, arcs are described with a radius of 25 toises, so as to intersect each other in d ; then the lines drawn from this intersection to the point b, c , will be the faces of the places of arms. If lines are drawn parallel to the lines which terminate the covert-way, and the places of arms, at 20 toises distant from them, the space x, x, z , between these lines and those which terminate the covert-way, will be the glacis. At the extremities of the places of arms, are traverses made, such as r , which serve to inclose them; these traverses are three toises thick, and as long as the covert-way is broad, and a passage is cut in the glacis round them, of about six or eight feet, in order to have a free communication with the rest of the covert-way. There are also traverses of the same dimensions before every salient angle of the bastion and out-works, and are in the same direction as the faces of those works produced; and the thickness lies at the same side as the parapets. The passages round these last traverses are likewise from six to eight feet wide. In each place of arms are two sally-ports z, z , which are 10 or 12 feet wide, for the troops to sally out; in time of a siege they are shut up, with barriers of gates.

CONSTRUCTION OF ARROWS AND DETACHED REDOUBTS.

An arrow is a work made before the salient angles of the glacis, such as A , fig. 1. It is composed of a parapet of three toises thick, and 40 long; and the ditch before it five toises, terminating in a slope at both ends. The communication from the covert-way into these arrows is four or five toises wide; and there is a traverse, r , at the entrance, of three toises thick, with a passage of six or eight feet round it. A detached redoubt is a kind of work much like a ravelin, with flanks placed beyond the glacis; such as B ; they are made to occupy some spot of ground which might be advantageous to the besiegers; likewise to oblige the enemy to open their trenches farther off than they would do otherwise. Their distance from the covert-way ought not to exceed 120 toises, that it may be defended by musket-shot from thence. The gorge ab is 40 toises; the flanks ac, bf , which are perpendicular to the gorge, 10; and the faces cd, fd , 30: the ditch before it is six toises, ending in slopes at both ends; the covert-way four; the branches of the covert-way 42 toises long, or thereabouts; the faces of the places of arms y, y , which are perpendicular to the branches, 10; and the other, which is parallel to them, 14. The communication from the covert-way into the redoubt, is five or six toises wide; a traverse is made just at the entrance, and another in the middle when it is pretty long. The parapets of this communication terminate in a slope or glacis. If these redoubts are above 50 toises distant from the covert-way, the besiegers carry their trenches round, and enter through the gorge; by which means the troops that are in them are made prisoners of war, if they do not retire betimes; to prevent which, some other outworks should be made to support them.

CONSTRUCTION OF SECOND DITCHES AND COVERT-WAYS.

Plate LXXV, fig. 2. When the ground is low, and water to be found, there is often a ditch about 10 or 12 toises made round the glacis; and opposite to the places of arms are constructed lunettes, beyond the ditch: such as D , whose breadth on the counterscarp of the ditch is 10 toises, from b to a and from c to d ; and the faces $a L, d L$, are parallel to those of the places of arms; the ditch be-

fore them is from eight to ten toises wide. The second covert-way is four toises, the semi-gorges of the places of arms, m , about 15, and the faces perpendicular to the counterscarp; the second glacis is from 15 to 18 toises broad. This second covert-way has traverses every where, in the same manner as the first.

CONSTRUCTION OF PROFILES.

A PROFILE is the representation of a vertical section of a work; it serves to shew those dimensions which cannot be represented in plans, and is necessary in the building of a fortification. Profiles are generally constructed upon 30 feet to an inch. It would be endless to describe all their particular dimensions; we shall therefore lay down the principal rules only, given by M. Vaudan, on this subject. Every work ought to be at least six feet higher than that before it, so that it may command those before it; that is, that the garrison may fire from all the works at the same time, with great and small arms, at the besiegers in their approaches. Notwithstanding this specious pretence, several authors object against it. For, say they, if you can discover the enemy from all the works, they can discover, by the same reason, all the works from their batteries; so that they may destroy them without being obliged to change their situation, and thereby dismount all the guns of the place before they come near it. But if all the works were of the same height, those within cannot be destroyed, till such time as those before them are taken: guns might be placed in the covert-way and outworks to obstruct the enemy's approach; and when they come near the place, they might be transported into the inner works: and as the body of the place would be much lower, the expence would be considerably diminished. But when works are low, they are easily enfiladed by the ricochet batteries, which is a kind of firing with a small quantity of powder, by giving the gun an elevation of 10 or 12 degrees: this might, however, be partly prevented, by making the parapets near the salient angles, for the space of eight toises on each side, five or six feet higher than the rest of the works. 2. The covert-way should be lower than the level ground, otherwise the body of the place must be raised very high, especially where there are several outworks: this is to be understood only when the works exceed each other in height, otherwise it need not be below the level. 3. The bases of all inward slopes of earth should be at least equal to the height, if not more. 4. The bases of all outward slopes of earth, two-thirds of their heights. 5. The slopes of all walls or revetments should be one-fifth of their height; or one-sixth might perhaps be sufficient; the height of a wall is estimated from the bottom of the ditch, and not from the beginning of its foundation. 6. The slopes of all parapets and traverses are one-sixth of their breadth; that is, three feet towards the field; or the inside, where the banquettes should be three feet higher than the outside. 7. When the revetment of a rampart goes quite up to the top, four feet of the upper part is a vertical wall of three feet thick, with a square stone at the top of it projecting six inches; and a circular one below, or where the slope begins, of eight or ten inches diameter: they go quite round the rampart, and the circular projection is called the cordon. Where the straight part of the wall ends and the slope begins, the wall is always made five feet thick; and the counterforts or buttresses reach no higher than that place. 8. When the rampart is partly walled and partly turfed, then one-fifth of the height which is turfed must be added to five feet, to get the thickness of the wall above. And having the thickness of any wall above, by adding one-fifth of its height from the bottom of the ditch, the sum will be the thickness of the wall at the bottom; but if a sixth part is only taken for the slope, then a sixth part must be added. For instance, suppose a rampart of 30 feet high from the bottom of the ditch, and that 10 of these are to be turfed, then the fifth part of 10, which is 2, added to 5, gives 7 for the wall above; and as this wall is 20 feet high, the fifth of which added is 4, and 4 to the thickness 7 above, gives 11 for the thickness near the foundation. In fig. 1, Plate LXXIII, AL represents the horizontal line of a profile, in which the principal elevations and depressions are exhibited as explained in the definitions; fig. 2, 3, and 4 represent, in military perspective, the profiles of the body of a place, the ravelin and covert-way; which gives a clear idea of what is meant by a profile, and from which those of all other works may be easily conceived.

OF IRREGULAR FORTIFICATION.

IRREGULAR FORTIFICATION is that where the sides and angles are not uniform, equidistant, or equal; owing to the irregularity of the ground, hills, valleys, rivers, and the like. The most essential principle in fortification consists in making all the fronts of a place equally strong, so that the enemy may find no advantage in attacking either of the sides. This can happen no otherwise in a regular fortification situated in a plain or even ground: but as there are but few places which are not irregular either in their works or situations, and the nature of the ground may be such as makes it impracticable to build them regular without too great expence; it is so much the more necessary to shew in what consists the strength or weakness of a town irregularly fortified, so that the weakest part may be made stronger by additional outworks; as likewise, if such a place is to be attacked, to know, which is the strongest or weakest part.

CONSTRUCTION OF AN IRREGULAR PLACE IN AN OPEN COUNTRY.

If the place to be fortified is an old town inclosed by a wall or rampart, as it most frequently happens, the engineer is to consider well all the different circumstances of the figure, situation, and nature, of the ground; and to regulate his plan accordingly, so as to avoid the disadvantages and gain all the advantages possible; he should examine, whether by cutting off some parts of the old wall or rampart, and taking in some ground, the place can be reduced into a regular form, or nearly so; for if that can be done without increasing the expence considerably, it should by no means be omitted. Old towns have often towers placed from distance to distance, as Douay, Tournay, and many other places, which are generally made use of, and meaded when it may be done. If there be a rampart without bastions or towers, it must be well considered whether bastions may not be added, or if it is not better to make only some outworks; if the ditch about this rampart is not too wide and deep, it would be advantageous to make detached bastions; otherwise ravelins and counterguards must be constructed. Special care must be taken to make all the sides of the polygon as nearly equal as possible, and that the length of the lines of defence do not exceed the reach of a musket-shot; but if that cannot be done, those sides which are on the narrowest part should be made the longest. If some of the sides be inaccessible or of very difficult approach, either on account of some precipice, marshy ground, or inundation, they may be made much longer than the others which are easy of access, and the flanks need not be so large as the rest; by doing so some expence will be saved, which may be used in making the other sides stronger by adding more outworks. There are few situations but what are more advantageous in some parts than in others; it is therefore the business of an engineer to distinguish them, and to render those sides strong by art which are not so by nature. If the situation be low and watery, lunettes or tenailions, and such other small outworks, should be constructed; because they are not of any great expence, and may make a very good defence. But if one side of the place only be low, and running water is to be had, a second ditch and covert-way with lunettes may be made, by observing, that if the first glacis is made to slope, so as to become even with the level of the water in the second ditch; or if the water can be swelled by means of dykes or sluices, so as to overflow the best part of the glacis, it should be done: for by doing this these works will be able to make very good defence, since the besiegers will find it a difficult matter to lodge themselves upon this glacis; which cannot be done but within a few toises of the first covert-way, where the besieged are ready to receive them, and to destroy their works with great advantage; whereas the enemy cannot support their workmen but from the second covert-way, which is too far off to be of any great service to them. But if the situation be dry, without any water about it, caponiers should be made in the great ditch, from the curtains to the ravelin, and batteries raised in the entrance of the ditch before the ravelin, whose parapet must slope off into a glacis, so as to afford no cover for the enemy behind them. Arrows and detached redoubts are likewise very proper to be used in such a case; and sometimes horn or crown works, if it should be thought convenient; but these works should never be constructed without an absolute necessity, either to oc-

cupy a spot of ground which might be advantageous to the enemy, or to cover some gate or entrance in the town; for they are of great expence, and their defence seems not to be answerable to it. Most of the places in Flanders are fortified with horn-works, such as Ypres, Fournay, Lille, and others. If the place to be fortified is new, and the situation will not admit of a regular construction, particular care must be taken in choosing such a spot of ground as is most advantageous, and least liable to any disadvantages either in the building or in maintaining it. All hills or rising grounds should be avoided, which might command any part of the works; marshy grounds, because such situations are unwholesome; or lakes and standing waters for the same reason, excepting a lake is or may be made navigable. Good water should be had either within the place or near it, for it is absolutely necessary for men and cattle: the air should be wholesome; otherwise the continual sickness that may reign in such a place might prevent people from coming to live in it, and the garrison would not be in a condition to defend themselves as they ought to do. In short, all the different circumstances attending such an undertaking should be maturely considered before a resolution is taken to fortify any place. When a situation is fixed upon, the next thing to be considered is, the bigness of the town and the number of its outworks; which must absolutely depend upon the consequence such a place is of to a nation. If it is only to guard a pass or entrance into a country, it need not be so large: but if it is to be a place either to promote or to protect trade, it should be large and commodious; the streets should be wide, and the buildings regular and convenient. As to what regards the fortification, its construction should depend on the nature of the situation, and the number of works on the funds or expence a prince or nation will be at; which, however, ought to be according to the benefit arising from such a place: for as such undertakings are of very great expence, an engineer cannot be too sparing in his works; on the contrary, the greatest economy should be used both in regard to the number of works and to their construction. The body of the place may have revetments quite up to the top, or only in part, and the rest turfed; but as to the outworks they should have half-revetments, or they may be made with turf only; as being not so necessary to prevent the place from being surprised, which may nevertheless make a good defence. Plate LXXIII. fig. 5, is the plan of an octagon, one-half of which is similar and equal to the other half. The exterior sides are each 180 toises, and the works are constructed according to our method; but because the sides AB, EF, are weaker than the rest, we have added tenailles, redoubts in the ravelins, and lunettes, to render them nearly equal in strength with the others; and if counter-guards were made before the bastions A and B, it would effectually secure that front. Instead of lunettes, any other works may be made, as may be thought convenient and according to the nature of the ground. If it should be judged necessary to add other outworks to the ravelins all round the place, care must be taken to add likewise more to the fronts AB, EF, in order to render the advantages and disadvantages of attacking on either side equal.

CONSTRUCTION OF AN IRREGULAR FORTIFICATION ON A HILL OR ROCK.

In the construction of such places, care must be taken that no neighbouring hill commands any part of the works. The town should always be built on the highest part; but if it should be thought more convenient to place it lower, then the upper part must be fortified with a fort. The situation should be made as nearly level as possible, by removing the earth from some places to fill up others; and if it cannot well be levelled without extraordinary expence, works must be made on the highest part, so as to command and protect the lower. The works ought to occupy all the upper part of the hill; but if it should be too extensive to be all inclosed, or so irregular as not to be fortified without great inconvenience, the parts which fall without should be fortified with some detached works, and a communication with the place must be made either above or below the ground. There should be no cavity or hollow roads within cannon-shot round about the place, where the enemy might be able to approach under cover. If there be a spring near the top of the hill, it should be inclosed in the fortification; or if that cannot be done, by some work or other; for there is nothing more necessary, and at the same time

6 H.

more scarce, in such situations, than water for which reason they cannot be too much care taken to provide it: several cisterns should be made to receive the rain-water, and to preserve it; wells should be dug likewise, though ever so deep, the water of which will serve for common use. Fortified towns built on hills or rocks should never be large; for their use is generally to guard passes or inlets into a country, as they are seldom useful in traffic; and it is a difficult matter to provide for a large garrison in such situations, neither should any such place be built without some very material reasons: but when it is absolutely necessary, great care and precaution should be taken to render the works as perfect as the situation will admit of, and at the same time to be as frugal in the expence as possible.

CONSTRUCTION OF IRREGULAR FORTIFICATIONS NEAR RIVERS, LAKES, OR THE SEA.

As the intent of building these kinds of places is chiefly to facilitate and protect trade, they are of more importance than any other kind, especially in maritime countries, where the principal strength and power of the state depends on them: for which reason we shall treat of this construction the more largely. The first thing to be considered is their situation, which ought to be such as to afford a good harbour for shipping, or a safe and easy entrance in stormy weather; but as it is hardly possible to find any harbour, where ships may go in and lie secure with all winds, care should be taken to make them safe to enter with those winds which are most dangerous: but it is not sufficient that the harbour is safe against stormy weather; it should likewise be so against an enemy both by land and water; for it often happens that ships are destroyed where it was imagined they were secure, which is of too great consequence not to be provided against; for which reason, forts or batteries must be built in the most convenient places, to prevent the enemy's ships from coming too near, so as to be able to cannonade those in the harbour, or fling shells amongst them; and if there is any danger of an enemy's approach by land, high ramparts and edifices must be built, so as to cover them. When a river is pretty large, and it is not convenient to make a harbour without great expence, the ships may ride along the shore; which, for that reason, must be made accessible for ships of burden: this may be done by advancing the quay into the river if the water is too shallow, or by digging the river sufficiently deep for that purpose. And to prevent an enemy from coming up to the river, forts must be built on both sides, especially when there are any turnings or windings. Antwerp is such a place: for the Scheld is sufficiently deep to carry ships of great burden, which may come quite near the town-wall; and several forts are built below it on both sides, so that it would not be an easy matter for an enemy to come up the river. When the river is small, so that no ships of burden can come through it, it is sufficient to make it run through some of the works, where proper landing places are contrived, from whence the goods may be carried into the place; as at Sarre-Louis, where a horn-work is built beyond the Sarre, in the George of which the goods are landed. If the breadth of the river do not exceed 200 yards, it commonly passes through the middle of the town, and proper quays are made on each side; in such a case, the fortification is so contrived, as that the river passes through the curtain, in order to have a bastion on each side to

defend the coming in and going out. When M. Vauban fortified near rivers, he made always the exterior side near the water much longer than any of the others; such as Huningen on the Rhine, and Sarre-Louis on the Sarre; but for what reason he fortified these places in that manner, has not been told by any author. But it is plain that the sides which terminate at the river are the weakest; because the besiegers' trenches being secured by the river, they may draw most of their troops off, and act therefore with more vigour and strength on the other side: besides, as the strength of a side increases in proportion as the angle of the polygon is greater, by making the side next the river longer, the angles at its extremities become wider, and consequently the adjacent sides stronger. There are other advantages, besides those mentioned, which arise from the lengthening of that side; for if the river is deep so as not to be fordable, that side is not liable to be attacked; and by increasing its length, the capacity of the place increases much more in proportion to the expence, than if more sides were made; the centre of the place will be likewise nearer the river, which makes it more convenient for transporting the goods from the water-side to any part of the town. To illustrate this method of M. Vauban's, we have given the plan of Huningen. See Plate LXXIII. fig. 6. This place was built for the sake of having a bridge over the Rhine, for which reason he made it only a pentagon; the side AB next to the river is 200 toises, and each of the others but 180. About the space abc , which lies before the front AB, is a stone-wall; and the passages are shut up with sluices, to retain the water in the ditches in the dry seasons: and to prevent an enemy from destroying the sluice near the point c , whereby the water would run out and leave the ditches dry, the redoubt y was built in the little island hard by, in order to cover that sluice; without which precaution the place might be insulted from the river-side, where the water is shallow in dry seasons. The hornwork K beyond the Rhine was built to cover the bridge; but as this work cannot be well defended, across the river, the hornwork H was made to support the other. Before finishing the description of this plan, we shall shew how to find the long side AB. After having inscribed the two sides GE, GF, in a circle, draw the diameter CD, parallel to the line joining the points EF. On this diameter set off 100 toises on each side of the centre; from these points draw two indefinite perpendiculars to the diameter: then if from the points EF, as centres, two arcs are described with a radius of 180 toises, their intersections A and B with the said perpendiculars, will determine the long side AB, as likewise the other two FB and EA. In like manner may be found the long or short side of any polygon whatsoever. When a town near a river is to be fortified for the safety of commerce, particular care should be taken in leaving a good space between the houses and the water-side, to have a key or landing-place for goods brought by water; it should also be contrived to have proper places for ships and boats to lie secure in stormy weather, and in time of a siege; and as water-carriage is very advantageous for transporting goods from one place to another, as well as for bringing the necessary materials, not only for building the fortifications but also the place itself, the expences will be lessened considerably when this convenience can be had; for which reason, places should never be built any where else but near rivers, lakes, or the sea; excepting in extraordinary cases, where these advantages cannot be obtained.

FORTINS, FORTELETS, or FIELD-FORTS, are little forts, whose flanked angles are generally 120 fathoms distant from one another. The extent and figure of fortins are different, according to the situation and nature of the ground; some having whole bastions, and others demi-bastions. They are used only for a time, either to defend the lines of circumvallation, or to guard some passage or dangerous post.

FORTISSIMO, in music, sometimes denoted by FFF, or *fff*, signifies to sing or play very loud or strong.

FORTITUDE, is generally considered as the same with courage, but in a more accurate view they are clearly distinguishable: Courage may be a virtue or vice, according to circumstances:

fortitude is always a virtue: we speak of desperate courage, but not of desperate fortitude. A contempt or neglect of danger, without regard to consequences, may be called courage; and this some brutes have as well as we: in them it is the effect of natural instinct chiefly; in man it depends partly on habit, partly on strength of nerves, and partly on want of consideration. But fortitude is the virtue of a rational and considerate mind, and is founded in a sense of honour and a regard to duty. There may be courage in fighting a duel: though that folly is more frequently the effect of cowardice: there may be courage in an act of piracy or robbery: but there can be no fortitude in perpetrating a crime. Fortitude implies a love of equity and of public good; for, as

Plato

MISCELLANIES.

Gores for Globes

W. R. Newman 1854

Plato and Cicero observe, courage exerted for a selfish purpose, or without a regard to justice, ought to be called audacity rather than fortitude. This virtue takes different names, according as it acts in opposition to different sorts of evil; but some of those names are applied with considerable latitude. With respect to danger in general, fortitude may be termed intrepidity; with respect to the dangers of war, valour; with respect to pain of body or distress of mind, patience; with respect to labour, activity; with respect to injury, forbearance; with respect to our condition in general, magnanimity. The motives to fortitude are many and powerful. This virtue tends greatly to the happiness of the individual, by giving composure and presence of mind, and keeping the other passions in due subordination. To public good it is essential; for without it, the independence and liberty of nations would be impossible. It gives to a character that elevation which poets, orators, and historians, have in all ages vied with one another to celebrate. Nothing so effectually inspires it as rational piety; the fear of God is the best security against every other fear. A true estimate of human life; its shortness and uncertainty; the numberless evils and temptations to which by a long continuance in this world we must unavoidably be exposed; with many similar considerations which Christianity affords, and especially the assurances of the Divine favour, are the only certain foundations of genuine fortitude in all exigencies.

FORTROSE, a town of Scotland in Ross-shire, on the Frith of Moray, nearly opposite to Fort George, 10 miles N. E. of Inverness.

FORTUNA, a goddess worshipped with great devotion by the ancient Greeks and Romans; who believed her to preside over human affairs, and to distribute wealth and honour at her pleasure. See **FORTUNE**.

FORTUNATE ISLANDS, in ancient geography, certain islands, concerning the situation of which authors are not agreed; famous in the mythology, for the golden apples of the Hesperides. The common opinion is, that they are the Canary Islands.

FORTUNE, [τοχμή], a name which among the ancients seems to have denoted a principle of fortuity, whereby things came to pass, without being necessitated thereto: but what and whence that principle is, they do not seem to have ever precisely thought. Hence their philosophers often intimate, that men only framed the phantom Fortune to hide their ignorance; and that they call Fortune whatever befalls a man without his knowing for what purpose. Hence Juvenal (Sat. x. ver. 366,) affirms, they were men who made a deity of Fortune: and Mr. Spence says, that he has seen an ancient gem, in which Cybele, the mother of the gods, is represented as turning away her head from Fortune, in attitude of disowning and rejecting her; (Polymetis, p. 150, 154, &c.) In the opinion of the heathens, therefore, fortune was only the arrival of things in a sudden and unexpected manner, without any apparent cause or reason: so that the philosophical sense of the word coincides with what is vulgarly called chance. But in religion it had a farther force; altars and temples in great numbers were consecrated to Fortune, as a deity. This intimates, that the heathens had personified, and even deified, Chance; and conceived her as a sort of goddess, who disposed of the fate of men at her pleasure. Hence that innovation of Horace, *O diva, gratum quæ regis Antium*, in the 35th ode of the first book, where he recommends Augustus, then preparing for a visit to Britain, to her protection. From these different sentiments it may be inferred, that the ancients at one time took Fortune for a peremptory cause, bent upon doing good to some, and persecuting others; and at others for a blind inconstant cause, without any view or determination at all. If then the word fortune had no certain idea in the mouth of those who erected altars to her, much less can it be ascertained what it denotes in the minds of those who now use the word in their writings. Horace paints Fortune preceded by Necessity, holding nails and wedges in her hands, with a cramp-iron and melted lead to fasten it; rarely accompanied with Fidelity, unless when she abandons a family; for in that case Fidelity never fails to depart with her, as well as friends. She is disrespectfully spoken of by most of the Roman writers, and represented as blind, inconstant, unjust, and delighting in mischief. The most celebrated temple of Fortune was at Præneste. Statius speaks of several Fortunes there, and calls them the Prænestinae sorores. Lib. i. Sylv. iii. ver. 80.

FORTUNE ISLAND, or **GOOD FORTUNE ISLAND**, an isle in the Indian sea, S. W. of Sumatra. Lon. 20. 25. E. Lat. 1. 35. S.

FORTUNETELLER, one who cheats common people, by pretending to the knowledge of futurity. Fortune-tellers are to be punished with a year's imprisonment, and standing four times on the pillory. Stat. 9 Geo. II. cap. 5.

FORTY-DAYS COURT, the court of attachment or woodmote, held before the verderors of the forest once every 40 days, to inquire concerning all offenders against vert and venison. See **ATTACHMENT**.

FORUM, in Roman antiquity, was a public place within the city, where causes were judicially tried, and orations delivered to the people.

FORUM was also used for a place of traffic, answering to our market-place. These were generally called *fora venalia*; in contradistinction to the former, which were called *fora civilia*. The Grecian *Αγορα* exactly correspond with the Roman *fora*, being places where courts and markets were held. At Athens they had many *fora*, but the chief of them were the old and the new.

FORUM is also used among casuists, &c. for jurisdiction; as, *In foro legis*, &c. The following metaphorical uses of the word are also common in the Classics, as Cicero, Suetonius, Florus, &c.

1. **FORUM AGERE**, denoted the bringing on causes out of Rome, in a Roman province; signifying the same with *agere conventum*.

2. **FORUM INDICERE**, was the act of the prator appointing the place in Rome where causes were to be tried.

FORUM, in ancient geography, prefixed to a proper name, denoted a market-town or borough.

FORUM APPII, a town of the Volsci, in Latium, on the Via Appia, a little beyond the *Tres Tabernæ*; mentioned by St. Luke, as well as by Cicero.

FORUM DOMITII, a town of Gallia Narbonensis; now Frontignan, or Frontigniac, in Languedoc.

FORUM FULVII, a town of Liguria, surnamed *Valentinum*; from which it is conjectured that it is now Valenza in the duchy of Milan.

FORUM TIBERII, a town of Gallia Belgica, on the left or W. side of the Rhine: Now called *Kaysersbuhl*.

FORUM VULCANI, the *Campi Phlegræi* of Pliny: a place in Campania, near Puteoli, and distant from it two miles towards Naples. It is now called *Solfatara*.

FOS, a marquisate of Italy, in Tuscany.

FOS DI NOVA, the capital of the above marquisate: four miles E. of Sarzana.

FOSS, in fortification, a hollow place, commonly full of water, lying between the scarp and counterscarp, below the rampart; and turning round a fortified place or a post that is to be defended.

FOSSA, in our ancient customs, was used to signify a ditch full of water, wherein women, convicted of felony, were drowned.

FOSS-WAY, one of the four principal high-ways of England, that anciently led through the kingdom; supposed to be made by the Romans, having a ditch upon one side.

FOSSANO, a town of Italy in Piedmont, seated on the Stura; famed for its medicinal springs; whence its ancient name *Fons Sanus*, since corrupted into its modern one. It lies five miles E. of Savigliano.

FOSSARH, in antiquity, officers in the eastern church, whose business was to inter the dead.

FOSSE, in geography, a town of Germany, in Westphalia, lately in the bishopric of Liege. It is seven miles W. of Namur.

FOSSE, the name of two rivers of England; viz. 1. in Lancashire, running into *Leven Sands*: 2. in Yorkshire, running into the *Ouse* near York.

FOSSIL, [*fossilis*, Lat. *fossile*, Fr.] in natural history, denotes in general all things dug out of the earth: whether they be natives thereof, as metals, stones, salts, earths, and other minerals; or extraneous, reposit in the bowels of the earth by some extraordinary means, as earthquakes, the deluge, &c. See **METAL**, **STONE**, **SHELL**, &c.

FOSSOMBRONE, a town of Italy, in the duchy of Urbino, 16 miles S. W. of Pesaro.

FOSTER, JAMES, D. D. a most distinguished and popular dissenting minister, born at Exeter in 1697. He began to preach in 1718; and strong disputes arising soon after, among the dissenters, concerning the Trinity and subscription to tests, his judgement determining him to the obnoxious opinions, the clamour grew loud

loud against him, and occasioned more than one removal. His talents were hid among obscure country congregations, until 1724; when he was chosen to succeed Dr. Gale in Barbican, where he laboured as pastor above 20 years. The Sunday evening lecture, begun in the Old Jury meeting-house in 1728, which he conducted with uncommon applause for more than twenty years, indisputably shewed his abilities as a preacher. Persons of all persuasions and ranks in life flocked to hear him: and Mr. Pope has honoured him with a commendatory couplet to his satires; which, however, his commentator laboured to destroy the intention of, by a frivolous note. In 1746 he attended Lord Kilmarnock, at his execution on Tower-hill; an office which his friends thought had made too deep an impression on his sympathizing spirit, as his vivacity abated from that time. He died in 1753; after having published several valuable compositions and sermons; particularly, 1. A Defence of Christianity, against Tindal's Christianity as old as the Creation. 2. An Essay on Fundamentals. 3. Four volumes of Sermons. 4. Discourses on Natural Religion and Social Virtue, in 4to.

FOSTER, SAMUEL, an ingenious mathematician of the 17th century, and astronomical professor in Gresham college, was one of that learned association which met for cultivating the new philosophy, during the political confusions, and which Charles II. established into the Royal Society. He died, however, in 1652, before this incorporation took place: but wrote several mathematical and astronomical treatises.

FOTHERGILL, JOHN, an eminent physician, born in 1712 at Car End in Yorkshire of reputable parents who were quakers. He took his doctor's degree at Edinburgh, in 1736. In the same year he became a pupil in St. Thomas's hospital, and in 1740 went abroad. On his return he settled in London: and in 1748 acquired a great reputation, by a tract, intitled, an Account of the Sore Throat attended with Ulcers. This disease was at that time very prevalent and fatal. In 1754 he became a member of the Edinburgh College of Physicians; and in 1763 a fellow of the Royal Society. When the differences broke out between this country and the American colonies, he laboured much to prevent hostilities, and had conferences with Dr. Franklin for that purpose. Dr. Fothergill was a man of amiable manners, a skilful physician, a great encourager of learning, and an excellent botanist. He died in 1780. His works have been printed in 3 vols. 8vo. with his life prefixed. He was at the expence of printing Purver's translation of the Bible, and an edition of Percy's Key to the New Testament, for a seminary of Quakers in Yorkshire. His brother Samuel was a considerable preacher among the Quakers, and died in 1773.

FOTHERGILLA, in botany, a genus of the polyandria digynia class and order. Calyx ament, ovate; scales one-flowered; corolla calyx-form, one-petaled, five-cleft. There is but one species.

FOTHERING, a peculiar method of endeavouring to stop a leak in the bottom of a ship while she is afloat, either under sail or at anchor. A basket is filled with ashes, cinders, and chopped rope-yarns, and loosely covered with a piece of canvas; to this is fastened a long pole, by which it is plunged repeatedly into the water, as close as possible to the place where the leak is conjectured to lie. The oakum or chopped rope-yarns being thus gradually shaken through the twigs, or over the top of the basket, are frequently sucked into the hole along with the water, so that the leak becomes immediately choked; and the future entrance of the water is thereby prevented.

FOTHERINGAY, a town of Northamptonshire, about four miles from Staneford, situated on the Avon.

FOUAN, a town of Asia, in Corea.

FOU-CHAN, a town of China, in the province of Chang-tong; 25 miles S. E. of Teng-tcheon.

FOUCHARMONT, a town of France, in the department of the Lower Seine; nineteen and an half miles S. of Dieppe, and three N. E. of Neufchatel.

FOUE, a large town of Egypt on the Nile, 25 miles S. of Rosetta, and 40 E. of Alexandria.

FOUESNANT, a town of France, in the department of Finistère, seven and a half miles S. of Quimper.

FOUGADE, [French,] in the art of war, a sort of little mine in the manner of a well, scarce more than ten feet wide, and twenty deep, dug under some work of fortification, and charged with barrels or sacks of gunpowder to blow it up, and covered over with earth.

FOUGERES, a town of France, in the department of Maine and Loire. It is 24 miles N. E. of Rennes.

FOUL, in sea-language, is used when a ship has been long untrimmed, so that the grass weeds, or branches, grow on her sides under water. It is also used for the running of one ship against another. This happens sometimes by the violence of the wind, and sometimes by the carelessness of the people on board, to ships in the same convoy, and to ships in port by means of others coming in. The damages occasioned by running foul, are of the nature of those in which both parties must bear a share. They are usually made half to fall upon the sufferer, and half upon the vessel which did the injury; but in cases where it is evidently the fault of the master of the vessel, he alone is to bear the damage.

FOUL, in husbandry, a disease in cattle, proceeding from blood, and a waterish rheum that falls down into the legs, and makes them swell.

FOUL WATER. A ship is said to make foul water, when, being under sail, she comes into such shoal-water, that though her keel do not touch the ground, yet it comes so near it, that the motion of the water under her raises the mud from the bottom.

FOULA, or FOUL ISLAND, one of the Shetland isles, lying between six and seven leagues W. from the main land.

FOULNESS, in geography, an island of England the S. E. coast of Essex, six miles E. of Rochford.

FOULNEY, an island on the coast of Lancashire, S. W. of the Sands.

FOULOU-SOUSOU, a town of Chinese Tartary, on the Saghalien, nine miles N. E. of Telden.

FOULSHAM, a town of Norfolk, 16 miles N. W. of Norwich.

FOUNDATION, in architecture, is that part of a building which is under ground. See ARCHITECTURE and BUILDING.

FOUNDATION, denotes also a donation or legacy, either in money or lands, for the maintenance and support of some community, hospital, school, &c.

FOUNDER, in a general sense, the person who lays a foundation, or endows a church, school, religious-house, or other charitable institution. The founder of a church may preserve to himself the right of patronage, or presentation to the living.

FOUNDER, also implies, an artists who cast metals, in various forms, for different uses, as guns, bells, statues, printing characters, candle-sticks, buckles, &c. whence they are denominated gun-founders, bell-founders, figure-founders, letter-founders, founders of small works, &c. See FOUNDRY.

FOUNDER, in glass-making, a term appropriated to the green glass, and is the person there who in the same office in the white-glass-making is called conciator.

FOUNDER, [*fondre*, Fr.] in sea-language is used, when a ship, by an extraordinary leak, or by a great sea breaking in upon her, is so filled with water, that she cannot be freed of it; so that she can neither veer nor steer, but lie like a log; and not being able to swim long, will at last sink.

FOUNDERED FEET. See FARRIERY.

FOUNDERY, a place where figures are formed of melted metal; a casting-house.

FOUNDERY, or FOUNDRY, signifies also the art of casting all sorts of metals into different forms.

FOUNDERY OF BELLS. The metal, it is to be observed, is different for bells from what is for statues; there being no tin in the latter; but there is one-fifth, and sometimes more, in the bell-metal. The dimensions of the core and the wax for bells, if a ring of bells especially, are not left to chance, but must be measured on a scale, or diapason, which gives the height, aperture, and thickness, necessary for the several tones required. It is on the wax that the several mouldings and other ornaments and inscriptions, to be represented in relievio on the outside of the bell, are formed; the clapper or tongue is not properly a part of the bell, but is furnished from other hands. In Europe, it is usually of iron, with a large knob at the extremity; and is suspended in the middle of the bell. In China, it is only a huge wooden mallet, struck by force of arm against the bell; whence they can have but little of that consonancy so much admired in some of our rings of bells. The Chinese have an extraordinary way of increasing the sound of their bells, viz. by leaving a hole under the cannon; which our bell-founders would reckon a defect. The proportions of our bells differ very much from those of the Chinese, as well as their sizes.

In ours, the modern proportions are, to make the diameter 15 times the thickness of the brim, and the height 12 times. The parts of a bell are, 1. The sounding bow, terminated by an inferior circle, which grows thinner and thinner. 2. The brim or that part of a bell whereon the clapper strikes, and which is thicker than the rest. 3. The outward sinking of the middle of the bell, or the point under which it grows wider to the brim. 4. The waist or furniture, and the part that grows wider and thicker quite to the brim. 5. The upper vase, or that part which is above the waist. 6. The pallet which supports the staple of the clapper within. 7. The bent and hollow branches of metal uniting with the cannons, to receive the iron keys, whereby the bell is hung up to the beam, which is its support and counterpoise, when rung out. The business of bell-foundry is reducible to three particulars. 1. The proportion of a bell. 2. The forming of the mould. And, 3. The melting of the metal. There are two kinds of proportions, viz. the simple and the relative; the former are those proportions only that are between the several parts of a bell to render it sonorous; the relative proportions establish a requisite harmony between several bells. The method of forming the profile of a bell, previous to its being cast, in which the proportion of the several parts may be seen, is as follows: the thickness of the brim, Cr, Plate LXX. fig. 14, is the foundation of every other measure, and is divided into three equal parts. First, draw the line HD, which represents the diameter of the bell; bisect it in F, and erect the perpendicular Ff; let DF and HF be also bisected in E and G, and two other perpendiculars Ee, Ga, be erected at E and G: GE will be the diameter of the top or upper vase, i. e. the diameter of the top will be half that of the bell; and it will, therefore, be the diameter of a bell which will sound an octave to the other. Divide the diameter of the bell, or the line HD, into 15 equal parts, and one of these will give Cr, the thickness of the brim; divide again each of these 15 equal parts into three other equal parts, and then form a scale. From this scale take 12 of the larger divisions or two-15ths of the whole scale in the compass, and setting one leg in D describe an arc to cut the line Ee in N; draw ND, and divide this line into 12 equal parts; at the point I erect the perpendicular IC = 10, and CI will be the thickness of the brim = one-15th of the diameter: draw the line CD; bisect DN; and at the point of the bisection 6 erect the perpendicular GK = $\frac{1}{2}$ of the larger divisions on the scale. With an opening of the compass equal to twice the length of the scale or 30 brims, setting one leg in N, describe an arc of a circle, and with the same leg in K and the same opening, describe another arc to intersect the former; on this point of intersection as a centre, and with a radius equal to 30 brims, describe the arc NK; in 6 K produced take KB = $\frac{2}{3}$ of the larger measure of the scale or $\frac{2}{3}$ of the brim, and on the same centre with the radius 30 $\frac{2}{3}$ brims describe an arc AB parallel to NK. For the arc BC, take 12 divisions of the scale or 12 brims in the compass; find a centre, and from that centre, with this opening, describe the arc BC, in the same manner as NK or AB were described. There are various ways of describing the arc Kp; some describe it on a centre at the distance of nine brims from the points p and K; others, as it is done in the figure, on a centre at the distance only of seven brims from those points. But it is necessary first to find the point p, and to determine the rounding of the bell p l. For this purpose, on the point C as a centre, and with the radius C I, describe the arc I p n; bisect the part I, 2, of the line Dn, and erecting the perpendicular p m, this perpendicular will cut the arc I p n in m, which terminates the rounding I p. Some founders make the bendings K a third of a brim lower than the middle of the line DN; others make the part C I D more acute, and instead of making C I perpendicular to DN at I, draw it one-sixth of a brim higher, making it still equal to one brim; so that the line I D is longer than the brim G I. In order to trace out the top-part Na, take in the compass eight divisions of the scale or eight brims, and on the points N and D as centres, describe arcs to intersect each other in 8; on this point 8, with a radius of eight brims, describe the arc N b; this arc will be the exterior curve of the top or crown: on the same point 8 as a centre, and with a radius equal to $7\frac{2}{3}$ brims, describe the arc A e, and this will be the interior curve of the crown, and its whole thickness will be one-third of the brim. As the point 8 does not fall in the axis of the bell, a centre M may be found in the axis by describing, with the interval of 8 brims from the centres D and H, arcs which will intersect in M;

and this point may be made the centre of the inner and outer curves of the crown as before. The thickness of the cap, which strengthens the crown at Q, is about one-third of the thickness of the brim; and the hollow branches or ears about one-sixth of the diameter of the bell. The height of the bell is in proportion to its diameter as 12 to 15, or in the proportion of the fundamental sound to its third major: whence it follows that the sound of a bell is principally composed of the sound of its extremity or brim, as a fundamental of the sound of the crown which is an octave to it, and of that of the height which is a third. The particulars necessary for making the mould of a bell are, 1. The earth: the most cohesive is the best: it must be well ground and sifted, to prevent any chinks. 2. Brick-stone; which must be used for the mine, mould, or core, and for the furnace. 3. Horse-dung, hair, and hemp, mixed with the earth, to render the cement more binding. 4. The wax for inscriptions, coats of arms, &c. 5. The tallow equally mixed with the wax, in order to put a slight lay of it upon the outer mould, before any letters are applied to it. 6. The coals to dry the mould. For making the mould, they have a scaffold consisting of four boards, ranged upon tressels. Upon this they carry the earth, grossly diluted, to mix it with horse-dung, beating the whole with a large spatula. The compasses of construction are the chief instrument for making the mould: They consist of two different legs joined by a third piece. And last of all, the founders' shelves, on which are the engravings of the letters, cartridges, coats of arms, &c. They first dig a hole of a sufficient depth to contain the mould of the bell, together with the case or cannon, under ground; and about six inches lower than the terreplain, where the work is performed. The hole must be wide enough for a free passage between the mould and walls of the hole, or between one mould and another, when several bells are to be cast. At the centre of the hole is a stake erected, that is strongly fastened in the ground. This supports an iron peg, on which the pivot of the second branch of the compasses turns. The stake is encompassed with a solid brick work, perfectly round, about half a foot high, and of the proposed bell's diameter. This they call a mill-stone. The parts of the mould are, the core, the model of the bell, and the shell. When the outer surface of the core is formed, they begin to raise the core, which is made of bricks that are laid in courses of equal height upon a lay of plain earth. At the laying of each brick, they bring near it the branches of the compasses, on which the curve of the core is shaped, so as that there may remain between it and the curve the distance of a line, to be afterwards filled up with layers of cement. The work is continued to the top, only leaving an opening for the coals to bake the core. This work is covered with a layer of cement, made of earth and horse-dung; on which they move the compasses of construction, to make it of an even smoothness every where. The first layer being finished, they put the fire to the core, by filling it half with coals, through an opening that is kept shut during the baking, with a cake of earth that has been separately baked. The first fire consumes the stake, and the fire is left in the core half, or sometimes a whole day: the first layer being thoroughly dry, they cover it with a second, third, and fourth; each being smoothed by the board of the compasses, and thoroughly dried before they proceed to another. The core being completed, they take the compasses to pieces, with intent to cut off the thickness of the model, and the compasses are immediately put in their place to begin a second piece of the mould. It consists of a mixture of earth and hair, applied with the hand on the core, in several cakes that close together. This work is finished by several layers of a thinner cement of the same matter, smoothed by the compasses, and thoroughly dried before another is laid on. The first layer of the model is a mixture of wax and grease spread over the whole. After which are applied the inscriptions, coats of arms, &c. besmeared with a pencil dipped in a vessel of wax in a chafing-dish: this is done for every letter. Before the shell is begun, the compasses are taken to pieces, to cut off all the wood that fills the place of the thickness to be given to the shell. The first layer is the same earth with the rest, sifted very fine; whilst it is tempering in water, it is mixed with cow's hair to make it cohere. The whole being a thin cullis, is gently poured on the model, that fills exactly all the sinuosities of the figures, &c. and this is repeated till the whole is two lines thick over the model. When this layer is thoroughly dried, they cover it with a second

of the same matter, but somewhat thicker; when this second layer becomes of some consistence, they apply the compasses again, and light a fire in the core, so as to melt off the wax of the inscriptions, &c. After this, they go on with the other layers of the shell, by means of the compasses. Here they add to the cow's hair a quantity of hemp, spread upon the layers, and afterwards smoothed by the board of the compasses. The thickness of the shell comes to four or five inches lower than the mill-stone before observed, and surrounds it quite close, which prevents the extravasation of the metal. The wax should be taken out before the melting of the metal. The ear of the bell requires a separate work, which is done during the drying of the several incrustations of cement. It has seven rings: the seventh is called the bridge, and unites the others, being a perpendicular support to strengthen the curves. It has an aperture at the top, to admit a large iron peg, bent at the bottom; and this is introduced into two holes in the beam, fastened with two strong iron keys. There are models made of the rings, with masses of beaten earth, that are dried in the fire, in order to have the hollow of them. These rings are gently pressed upon a layer of earth and cow's hair, one-half of its depth: and then taken out, without breaking the mould. This operation is repeated 12 times for 12 half-moulds, that two and two united may make the hollows of the six rings; the same they do for the hollow of the bridge, and bake them all, to unite them together. Upon the open place left for the coals to be put in, are placed the rings that constitute the ear. They first put into this open place the iron ring to support the clapper of the bell; then they make a round cake of clay, to fill up the diameter of the thickness of the core. This cake, after baking, is clapped upon the opening, and soldered with a thin mortar spread over it, which binds the cover close to the core. The hollow of the model is filled with an earth, sufficiently moist to fix on the place, which is strewed at several times upon the cover of the core; and they beat it gently with a pestle, to a proper height; and a workman smooths the earth at top with a wooden trowel dipped in water. Upon this cover, to be taken off afterwards, they assemble the hollows of the rings. When every thing is in its proper place, they strengthen the outside of the hollows with mortar, in order to bind them with the bridge, and keep them steady at the bottom, by means of a cake of the same mortar, which fills up the whole aperture of the shell. This they let dry, that it may be removed without breaking. To make room for the metal, they pull off the hollows of the rings, through which the metal is to pass, before it enters into the vacuity of the mould. The shell being unloaded of its ear, they range under the mill-stone five or six pieces of wood, about two feet long, and thick enough to reach almost the lower part of the shell; between these and the mould, they drive in wooden wedges with a mallet, to shake the shell off the model whereon it rests, so as to be pulled up and got out of the pit. When this and the wax are removed, they break the model and the layer of earth, through which the metal must run, from the hollow of the rings, between the shell and the core. They smoke the inside of the shell, by burning straw under it, that helps to smooth the surface of the bell. Then they put the shell in the place, so as to leave the same interval between that and the core; and before the hollows of the rings or the cap are put on again, they add two vents, that are united to the rings, and to each other, by a mass of baked cement. After which they put on this mass of the cap, the rings, and the vent, over the shell, and solder it with thin cement, which is dried gradually by covering it with burning coals. Then they fill up the pit with earth, beating it strongly all the time round the mould. The surface has a place for the fire, and another for the metal. The fire-place has a large chimney with a spacious ash-hole. The furnace which contains the metal is vaulted, whose bottom is made of earth, rammed down; the rest is built with brick. It has four apertures; the first, through which the flame revivifies; the second is closed with a stopple that is opened for the metal to run; the others are to separate the dross or scoria of the metal by wooden rakes: through these last apertures passes the thick smoke. The ground of the furnace is built sloping, for the metal to run down.

2. **FOUNDRY OF GREAT GUNS, AND MORTAR-PIECES.** The method of casting these pieces is different from that of bells: they are run massy, without any core, being determined by the hollow of the shell; and they are afterwards bored with a steel trepan, that

is worked either by horses or a water-mill. For the metal, parts, proportions, &c. of these pieces, see GUNNERY.

3. **FOUNDRY OF LETTERS, OR CASTING OF TYPES FOR PRINTING.** In the business of cutting, casting, &c. letters for printing, the letter-cutter must be provided with a vice, hand-vice, hammers, and files of all sorts such as watch-makers use; also gravers and sculptors of all sorts, and an oil-stone, &c. suitable and sizeable to the several letters to be cut: a flat gauge made of box to hold a rod of steel, or the body of a mould, &c. exactly perpendicular to the flat of the using file: a sliding gauge whose use is to measure and set off distances between the shoulder and the tooth, and to mark off from the end, or from the edge of the work, a face-gauge, which is a square notch cut with a file into the edge of a thin plate of steel, iron, or brass, of the thickness of a piece of common tin, whose use is to proportion the face of each sort of letter, viz. long letters, ascending letters, and short letters. So there must be three gauges, and the gauge for the long letters is the length of the whole body supposed to be divided into 42 equal parts. The gauge for the ascending letters Roman and Italic are five-sevenths, or 30 parts of 42, and 33 parts for the English face. The gauge for the short letters is three-sevenths, or 18 parts of 42 of the whole body for the Roman and Italic, and 22 parts for the English face. The Italic and other standing gauges are to measure the scope of the Italic stems, by applying the top and bottom of the gauge to the top and bottom lines of the letters, and the other side of the gauge to the stem; for when the letter complies with these three sides of the gauge, that letter has its true shape. The next care of the letter-cutter is to prepare good steel punches, well tempered, and quite free from all veins of iron; on the face of which he draws or marks the exact shape of the letter with pen and ink if the letter be large, or with a smooth blunted point of a needle if it be small; and then with sizeable and proper-shaped and pointed gravers and sculptors, digs or sculps out the steel between the strokes or marks he made on the face of the punch, and leaves the marks standing on the face. Having well-shaped the inside strokes of his letter, he deepens the hollows with the same tools; for if a letter be not deep in proportion to its width, it will, when used at press, print black, and be good for nothing. This work is generally regulated by the depth of the counter-punch. Then he works the outside with proper files till it be fit for the matrice. Before we proceed to the sinking and justifying of the matrices, we must provide a mould to justify them by. See Plate LXX, fig. 15 and 16. Every mould is composed of an upper and an under part. The under part is delineated in fig. 15. The upper part is marked fig. 16, and is in all respects made like the under part, excepting the stool behind, and the bow or spring also behind; and excepting a small roundish wire between the body and carriage, near the break, where the under part hath a small rounding groove made in the body. This wire, or rather half-wire, in the upper part makes the nick in the shank of the letter, when part of it is received into the groove in the under part. These two parts are so exactly fitted and gauged into one another (viz. the male-gauge marked *c* in fig. 16, into the female marked *g* in fig. 15,) that when the upper part of the mould is properly placed on, and in the under part of the mould, both together make the entire mould, and may be slid backwards for use so far, till the edge of either of the bodies on the middle of either carriage comes just to the edge of the female gauges cut in each carriage: and they may be slid forward so far, till the bodies on either carriage touch each other: and the sliding of these two parts of the mould backwards makes the shank of the letter thicker, because the bodies in each part stand wider asunder; and the sliding them forwards makes the shank of the letter thinner, because the bodies on each part of the mould stand closer together. The parts of the mould are as follows: viz. *a*, The carriage. *b*, The body. *c*, The male gauge. *d e*, The mouth-piece. *f i*, The register. *g*, The female gauge. *h*, The hag. *a a a a*, The bottom-plate. *b b b*, The wood on which the bottom-plate lies. *c c c*, The mouth. *d d*, The throat. *e d d*, The pallet. *f*, The nick. *g g*, The stool. *h h*, The spring or bow. Then the mould must be justified: and first the founder justifies the body, by casting about 20 proofs or samples of letters; which are set up in a composing stick, with all their nicks towards the right hand; and then by comparing these with the pattern-letters, set up in the same manner, he finds the exact measure of the body to be cast. He also tries

if the two sides of the body are parallel, so that the body be no bigger at the head than at the foot, by taking half the number of his proofs and turning them with their heads to the feet of the other half; and if then the heads and the feet be found exactly even upon each other, and neither to drive out nor get in, the two sides may be pronounced parallel. He farther tries whether the two sides of the thickness of the letter be parallel, by first setting his proofs in the composing-stick with their nicks upwards, and then turning one-half with their heads to the feet of the other half; and if the heads and feet lie exactly upon each other, and neither drive out nor get in, the two sides of the thickness are parallel. The mould thus justified, the next business is to prepare the matrices. A matrice is a piece of brass or copper of about an inch and a half long, and of a thickness in proportion to the size of the letter it is to contain. In this metal is sunk the face of the letter intended to be cast, by striking the letter-punch about the depth of an n. After this the sides and face of the matrice must be justified, and cleared with files of all bunnings made by sinking the punch. Every thing thus prepared, it is brought to the furnace; which is built of brick upright, with four square sides, and a stone on the top, in which stone is a wide round hole for the pan to stand in. A foundry of any extent has several of these furnaces in it. As to the metal of which the types are to be cast, this, in extensive foundries, is always prepared in large quantities; but cast into small bars, of about 20 pounds weight, to be delivered out to the workmen as occasion requires. In the letter-foundry which has been long carried on with reputation under the direction of Dr. Alex. Wilson and sons at Glasgow, we are informed, that a stock of metal is made up at two different times of the year, sufficient to serve the casters at the furnace for six months each time. For this purpose, a large furnace is built under a shade, furnished with a wheel-vent, in order the more equally to heat the sides of a strong pot of cast iron, which holds, when full, 15 cwt. of the metal. The fire being kindled below, the bars of lead are let softly down into the pot, and their fusion promoted by throwing in some pitch and tallow, which soon inflame. An outer chimney, which, is built so as to project about a foot over the farthest lip of the pot, catches hold of the flame by a strong draught, and makes it act very powerfully in melting lead; whilst it serves at the same time to convey away all the fumes, &c. from the workmen, to whom this laborious part of the business is committed. When the lead is thoroughly melted, a due proportion of the regulus of antimony and other ingredients are put in, and some more tallow is inflamed to make the whole incorporate sooner. The workmen, having mixed the contents of the pot very thoroughly by stirring long with a large iron ladle, next proceed to draw the metal off into the small troughs of cast iron, which are ranged to the number of 80 upon a level platform faced with stone, built towards the right hand. In the course of a day 15 cwt. of metal can be easily prepared in this manner; and the operation is continued for as many days as are necessary to prepare a stock of metal of all the various degrees of hardness. After this, the whole is disposed into presses according to its quality, to be delivered out occasionally to the workmen. The founder must now be provided with a ladle, which differs nothing from other iron ladles but in its size; and he is provided always with ladles of several sizes, which he uses according to the size of the letters he is to cast. Before the caster begins to cast, he must kindle a fire in the furnace to melt the metal in the pan: therefore he takes the pan out of the hole in the stone, and there lays in coals and kindles them; and, when they are well kindled, he sees the pan in again, and puts in metal into it to melt: if it be a small-bodied letter he casts, or a thin letter of great bodies, his metal must be very hot; nay sometimes red-hot, to make the letter come. Then having chosen a ladle that will hold about as much as the letter and break are, he lays it at the stoking-hole, where the flame bursts out, to heat. Then he ties a thin leather, cut with its narrow end against the face to the leather groove of the matrice by whipping a brown thread twice about the leather groove, and fastening the thread with a knot. Then he puts both halves of the mould together, and puts the matrice into the matrice-cheek, and places the foot of the matrice on the stool of the mould, and the broad end of the leather upon the wood of the upper half of the mould; but not tight up, lest it might hinder the foot of the matrice from sinking close down upon the stool in a train of work. Then laying a little rosin on the up-

per wood of the mould, and having his casting-ladle hot, he with the boiling side of it melts the rosin: and, when it is yet melted, presses the broad end of the leather hard down on the wood, and so fastens it to the wood; all this is the preparation. Now he proceeds to casting; placing the under half of the mould in his left hand, with the hook or lag forward, he clutches the ends of its wood between the lower part of the ball of his thumb and his three hind-fingers; then he lays the upper half of the mould upon the under half, so that the male gauges may fall into the female gauges, and at the same time the foot of the matrice places itself upon the stool; and clapping his left hand thumb strong over the upper half of the mould, he nimbly catches hold of the bow or spring with his right hand fingers at the top of it, and his thumb under it, and places the point of it against the middle of the notch in the back side of the matrice, pressing it both forwards towards the mould, and downwards by the shoulder of the notch close upon the stool; while at the same time with his hinder fingers he draws the under half of the mould towards the ball of his thumb, and thrusts by the ball of his thumb the upper part towards his fingers, that both the registers of the mould may press against both sides of the matrice, and his thumb and fingers press both halves of the mould close together. Then he takes the handle of his ladle in his right hand, and with the boll of it gives a stroke, or two or three, outwards upon the surface of the melted metal, to scum or clear it from the film or dust that may swim upon it; then he takes up the ladle full of metal, and having his mould, as aforesaid, in his left hand, he a little twists the left side of his body from the furnace, and brings the geat of his ladle (full of metal) to the mouth of the mould, and twists the upper part of his right hand towards him to turn the metal into it, while at the same moment of time he jilts the mould in his left hand forwards, to receive the metal with a strong shake (as it is called) not only into the body of the mould, but while the metal is yet hot, running swift and strongly, into the very face of the matrice, to receive its perfect form there, as well as in the shank. Then he takes the upper half of the mould off the under half, by placing his right hand thumb on the end of the wood next his left hand thumb, and his two middle fingers at the other end of the wood; and finding the letter and break lie in the under half of the mould (as most commonly, by reason of its weight, it does) he throws or tosses the letter, break and all, upon a sheet of waste paper laid for that purpose on the bench, just a little beyond his left hand, and is then ready to cast another letter as before; and also the whole number that is to be cast with the matrice. A workman will ordinarily cast about 3000 of these letters in a day. When the casters at the furnace have got a sufficient number of types upon the tables; a set of boys come and nimbly break away the jets from them: the jets are thrown into the pots, and the types are carried away in parcels to other boys, who pass them swiftly under their fingers, defended by leather, upon smooth flat stones, in order to polish their broad sides. This is a very dexterous operation, and is a remarkable instance of what may be effected by the power of habit and long practice; for these boys, in turning up the other side of the type, do it so quickly by a mere touch of the fingers of the left hand, as not to require the least perceptible intermission in the motion of the right hand upon the stone. The types, thus finely smoothed and flattened on the broad sides, are next carried to another set of boys, who sit at a square table, two on each side, and are there ranged up on long rulers, or sticks, fitted with a small projection, to hinder them from sliding off backwards. When these sticks are so filled, they are placed, two and two, upon a set of wooden pins fixed into the wall, near the dresser, sometimes to the amount of an hundred, in order to undergo the finishing operations. This workman, who is always the most expert and skilful in all the different branches carried on at the foundry, begins by taking one of these sticks, and, with a peculiar address, slides the whole column of types off upon the dressing-stick: this is made of well-seasoned mahogany, and furnished with two end-pieces of steel, a little lower than the body of the types, one of which is moveable so as to approach the other by means of a long screw-pin inserted in the end of the stick. The types are put into this stick with their faces next to the back or projection; and after they are adjusted to one another so as to stand even, they are then bound up, by screwing home the moveable end-piece. It is here where the great and requisite accuracy

of the moulds comes to be perceived; for in this case the whole column, so bound up, lies flat and true upon the stick, the two extreme types being quite parallel, and the whole has the appearance of one solid continuous plate of metal. The least inaccuracy in the exact parallelism of the individual type, when multiplied so many times, would render it impossible to bind them up in this manner, by disposing them to rise or spring from the stick by the smallest pressure from the screw. Now, when lying so conveniently with the narrow edges uppermost, which cannot possibly be smoothed in the manner before mentioned by the stones, the workman does this more effectually by scraping the surface of the column with a thick-edged but sharp razor, which at every stroke brings on a very fine smooth skin, like to polished silver; and he thus proceeds till in about half a minute he comes to the further end of the stick. The other edges of the types are next turned upwards and polished in the same manner. It is whilst the types thus lie in the dressing-stick that the operation of bearding or barbing is performed, which is effected by running a plane, faced with steel, along the shoulder of the body next to the face, which takes more or less off the corner, as occasion may require. Whilst in the dressing-stick they are also grooved, which is a very material operation. To understand this, it must be remembered, that when the types are first broken off from the jets some superfluous metal always remains, which would make them bear very unequally against the paper, whilst under the printing-press, and effectually mar the impression. That all these inequalities may, therefore, be taken away, and that the bearings of every type may be regulated by the shoulders imparted to them all alike from the mould, the workman or dresser proceeds in the following manner. The types being screwed up in the stick, as before mentioned, with the jet-end outermost, and projecting beyond the wood about one eighth of an inch, the stick is put into an open press, so as to present the jet-end uppermost, and then every thing is made fast by driving a long wedge, which bears upon a slip of wood, which lies close to the types the whole length: then a plane is applied, which is so constructed as to embrace the projecting part of the types betwixt its long sides, which are made of polished iron. When the plane is thus applied, the steel cutter bearing upon that part between the shoulders of the types where the inequalities lie, the dresser dexterously glides it along, and by this means strips off every irregular part that comes in the way, and so makes an uniform groove the whole length, and leaves the two shoulders standing; by which means every type becomes precisely like to another, as to the height against paper. The types being now finished, the stick is taken out of the press, and the whole column replaced upon the other stick; and after the whole are so dressed, he proceeds to pick out the bad letters, previous to putting them up into pages and papers. In doing this he takes the stick into his left hand, and turning the faces near to the light, he examines them carefully, and whenever an imperfect or damaged letter occurs, he nimbly plucks it out with a sharp bodkin, which he holds in the right hand for that purpose. Those letters which, from their form, project over the body of the type, and which cannot on this account be rubbed on the stones, are scraped on the broad sides with a knife or file, and some of the metal next the face pared away with a penknife, in order to allow the type to come close to any other. This operation is called kerning. The excellence of printing-types consists not only in the due performance of all the operations above described, but also in the hardness of the metal, form, and fine proportion of the character, and in the exact bearing and ranging of the letters in relation to one another.

4. **FOUNDRY OF SMALL WORKS, OR CASTING IN SAND.** The sand used for casting small works is at first of a pretty soft, yellowish, and clammy nature; but it being necessary to strew charcoal-dust in the mould, it at length becomes of a quite black colour. The red-hot metal, by burning part of the sand, contributes also to blacken it. This sand is worked over and over with a roller, on a board placed across a chest to receive it, after it is by these means sufficiently prepared, and freed from small stones or hard lumps of sand. This done, they take a smooth wooden board, of a length and breadth proportional to the things to be cast, and laying the first half of an open mould, or wooden frame, upon it, they place within it, upon the board, either wooden or metal models of what they intend to cast, and then fill it up with the prepared sand, a little moistened to make it cohere properly, pressing it upon the

patterns with the roller, so as to leave their impression in it. Along the middle of the mould is also laid half a small brass cylinder, to make an impression for the chief canal for the metal to run through, when melted, into the models or patterns; and from this chief canal are drawn several others, which extend to each model or pattern placed in the frame. Then placing the other half of the mould over the one with the patterns in it, so that the pins enter into the holes that correspond to them in the other, they proceed to work it in the same manner, so as to make the two cavities of the pattern fall exactly on each other. After both frames of the mould are thus finished, and their backs scraped smooth, they take out the patterns, first loosening them gently all round, that the sand may not give way. The moulds are then carried to the melter; who, after strewing mill-dust over them, dries them in a kind of oven for that purpose. Both parts of the mould being dry, they are again joined together by means of the pins; and to prevent their giving way, by reason of the melting metal passing through the chief cylindrical canal, they are screwed or wedged up in a pair of wooden screws, like a kind of press. When the moulds are thus prepared, the metal is melted in a crucible, of a size proportionate to the quantity of metal intended to be cast, and when brought to a proper heat, is poured into them at the mouth of the chief canal. When the moulds are coolish, the frames are unscrewed, and the cast work taken out of the sand, which is wet and worked over again for other castings.

5. **FOUNDRY OF STATUES.** The casting of statues depends on the due preparation of the pit, the core, the wax, the outer mould, the inferior furnace to melt off the wax, and the upper to fuse the metal. The pit is a hole dug in a dry place something deeper than the intended figure, and made according to the prominence of certain parts thereof. The inside of the pit is commonly lined with stone or brick; or, when the figure is very large, they sometimes work on the ground, and raise a proper fence to resist the impulse of the melted metal. The inner mould, or core, is a rude mass, to which is given the intended attitude and contours. It is raised on an iron grate, strong enough to sustain it, and is strengthened within by several bars of iron. It is generally made either of potter's clay, mixed with hair and horse-dung, or of plaster of Paris, mixed with brick-dust. The use of the core is to support the wax, the shell, and lessen the weight of the metal. The iron bars and the core are taken out of the brass figure through an aperture left in it for that purpose, which is soldered up afterwards. It is necessary to leave some of the iron bars of the core, that contribute to the steadiness of the projecting part, within the brass figure. The wax is a representation of the intended statue. If it be a piece of sculpture, the wax should be all of the sculptor's own hand, who usually forms it on the core: though it may be wrought separately in cavities, moulded on a model, and afterwards arranged on the ribs of iron over the grate; filling the vacant space in the middle with liquid plaster and brick-dust, whereby the inner core is proportioned as the sculptor carries on the wax. When the wax, which is the intended thickness of the metal, is finished, they fill small waxen tubes perpendicular to it from top to bottom, to serve both as canals for the conveyance of the metal to all parts of the work; and as vent-holes, to give passage to the air, which would otherwise occasion great disorder when the hot metal came to encompass it. The work being brought thus far, must be covered with its shell, which is a kind of crust laid over the wax, and which being of a soft matter, easily receives the impression of every part, which is afterwards communicated to the metal upon its taking the place of the wax, between the shell and the mould. The matter of this outer mould is varied according as different layers are applied. The first is generally a composition of clay, and old white crucibles well ground and sifted, and mixed up with water to the consistence of a colour fit for painting: accordingly they apply it with a pencil, laying it seven or eight times over, and letting it dry between whites. For the second impression they add horse-dung and earth to the former composition. The third impression is only horse-dung and earth. Lastly, the shell is finished by laying on several more impressions of this last matter, made very thick with the hand. The shell, thus finished, is secured by several iron girths, bound round it, at about half a foot distance from each other, and fastened at the bottom to the grate under the statue, and at top to a circle of iron where they all terminate. If the statue be so big that it would not be easy to move the moulds with safety, they must

be wrought on the spot where it is to be cast. This is performed two ways: in the first, a square hole is dug under ground, much bigger than the mould to be made therein, and its inside lined with walls of free-stone or brick. At the bottom is made a hole of the same materials, with a kind of furnace, having its aperture outwards: in this is a fire made to dry the mould, and afterwards melt the wax. Over this furnace is placed the grate, and upon this the mould, &c. formed as above. Lastly, at one of the edges of the square pit, is made a large furnace to melt the metal. In the other way, it is sufficient to work the mould above ground, but with the like precaution of a furnace and grate underneath. When finished, four walls are to be run around it, and by the side thereof a massive made for a melting furnace. For the rest the method is the same in both. The mould being finished, and inclosed as described, whether under ground or above it, a moderate fire is lighted in the furnace under it, and the whole covered with planks, that the wax may melt gently down, and run out at pipes contrived for that purpose, at the foot of the mould, which are afterwards exactly closed with earth, so soon as the wax is carried off. This done, the hole is filled up with bricks thrown in at random, and the fire in the furnace augmented till such time as both the bricks and mould become red hot. After this, the fire being extinguished, and every thing cold again, they take out the bricks, and fill up their place with earth moistened, and a little beaten to the top of the mould, in order to make it the more firm and steady. These preparatory measures being duly taken, there remains nothing but to melt the metal, and run it into the mould. This is the office of the furnace above described, which is commonly made in the form of an oven with three apertures, one to put in the wood, another for a vent, and a third to run the metal out at. From this last aperture, which is kept very close, while the metal is in fusion, a small tube is laid, whereby the melted metal is conveyed into a large earthen bason, over the mould, into the bottom of which all the big branches of the jets, or casts, which are to convey the metal into all the parts of the mould, are inserted. These casts or jets are all terminated with a kind of plugs, which are kept close, that, upon opening the furnace, the brass, which gushes out with violence, may not enter any of them, till the bason be full enough of matter to run into them all at once. Upon which occasion they pull out the plugs, which are long iron rods with a head at one end, capable of filling the whole diameter of each tube. The whole of the furnace is opened with a long piece of iron fitted at the end of each pole, and the mould filled in an instant. This completes the work in relation to the casting part; the rest being the sculptor's or carver's business, who, taking the figure out of the mould and earth wherewith it is encompassed, saws off the jets with which it appears covered over, and repairs it with chisels, gravers, puncheons, &c.

FOURMONT, STEPHEN, professor of the Arabic and Chinese languages, and one of the most learned men of his time, was born at Herbelai, a village 12 miles from Paris, in 1683. He studied in Mazarine college, and afterwards in the Seminary of Thirtysix. He was at length professor of Arabic in the Royal College, and was made a member of the Academy of Inscriptions. In 1738, he was chosen F. R. S. in London, and of that of Berlin in 1741. He was often consulted by the duke of Orleans, who greatly esteemed him, and made him one of his secretaries. He wrote a great number of books. The chief of those which have been printed are, 1. *The Roots of the Latin Tongue*, in verse. 2. *Critical Reflections on the Histories of Ancient Nations*, 2 vols. 4to. 3. *Meditationes Senecæ*, folio. 4. *A Chinese Grammar*, in Latin, folio. 5. *Several Dissertations* printed in the Memoirs of the Academy of Inscriptions, &c. He died at Paris in 1745.

FOURNEAUX ISLAND, a small circular island in the S. Pacific Ocean. Lon. 143. 2. W. Lat. 17. 11. S.

FOU-TCHOU, a city of China of the first rank in the province of Fo-kien, 870 miles S. of Peking.

FOU-TCHOU, a city of China of the first rank, in the province of Kiang-si; 735 miles E. of Peking.

FOWEY, FAWAY, or FOY, a populous and flourishing town of Cornwall, with a commodious haven on the British Channel. It lies 32 miles S. of Launceston. Lon. 4. 23. W. Lat. 50. 19. N.

FOWEY, FAWAY, FOUTH, or FOY, a river of Cornwall.

FOWL, among zoologists, denotes the larger sorts of birds, whether domestic or wild: such as geese, pheasants, partridges, turkies, ducks, &c. Tame fowl make a necessary part of the

stock of a country farm. See **POULTRY**. Fowls are again distinguished into two kinds, viz. land and water fowls, these last being so called from their living much in and about water: also into those which are accounted game, and those which are not. See **GAME**.

FOWLING, the art of catching birds by means of bird-lime, decoys, and other devices; or the killing of them by the gun. See **BIRD-CATCHING**, **BIRD-LIME**, **DECOY**, **SHOOTING**, and the names of the different birds in their order.

FOWLING, is also used for the pursuing and taking of birds with hawks, more properly called falconry, or hawking. See these articles.

FOWLING-PIECES, guns for birds; they are reckoned best, when they have a long barrel, from five feet and a half to six feet, with a moderate bore. But every fowler should have them of different sizes, suitable to the game he designs to kill. The barrel should be well polished and smooth within, and the bore of an equal bigness from one end to the other; which may be proved, by putting in a piece of pasteboard, cut of the exact roundness of the top: for if this goes down without stops or slipping, you may conclude the bore good. The bridge-pan must be somewhat above the touch-hole, and ought to have a notch to let down a little powder: this will prevent the piece from recoiling, which it would otherwise be apt to do.

FOX, GEORGE, the founder of the sect of Quakers, was a shoemaker in Nottingham. As he wrought at his trade, he used to meditate much on the scriptures: and conceiving that he was inspired, he began to preach. He proposed but few articles of faith; insisting chiefly on moral virtue, mutual charity, the love of God, and a deep attention to the inward motions and secret operations of the Spirit: he recommended a plain simple worship, and a religion without ceremonies, making it a principal point to wait in profound silence the directions of the Holy Spirit. Fox met with much rough treatment for his zeal, was often imprisoned, and several times in danger of being killed. But in spite of all discouragements his sect prevailed much, and many great men embraced his tenets; among whom were Barclay and Penn. He died in 1681. See **FRIENDS**.

FOX, JOHN, the martyrologist, was born at Boston in Lincolnshire, in 1517. At 16 he was entered a student of Brazen-nose college, Oxford; and in 1543, he proceeded M. A. and was chosen fellow of Magdalen college. He discovered an early genius for poetry, and wrote several Latin comedies, on Scriptural subjects, which his son assures us were written in an elegant style. He now applied himself with uncommon assiduity to divinity, particularly church-history; and, discovering a premature propensity to the doctrine of reformation, he was expelled the college as a heretic. His distress on this occasion was very great; but he soon found an asylum in the house of Sir Thomas Lucy of Warwickshire, who employed him as a tutor to his children. Here he married the daughter of a citizen of Coventry. Sir Thomas's children being grown up, after residing a short time with his wife's father, he came to London; where finding no immediate means of subsistence, he was reduced to the utmost degree of want; but as he was one day sitting in St. Paul's church, emaciated with hunger, a stranger accosted him familiarly, and, bidding him be of good cheer, put a sum of money into his hand; telling him at the same time, that in a few days new hopes were at hand. He was soon after taken into the family of the duchess of Richmond, as tutor to the earl of Surrey's children. In this family he lived, at Ryegate in Surrey, during the latter part of the reign of Henry VIII. the entire reign of Edward VI. and part of that of queen Mary I: but at length, persecuted by his implacable enemy Bishop Gardiner, he was obliged to seek refuge abroad. Basil in Switzerland was the place of his retreat, where he subsisted by correcting the press. On the death of Mary he returned to England; where he was graciously received by his former pupil the duke of Norfolk, who retained him in his family as long as he lived, and bequeathed him a pension at his death. Mr. secretary Cecil also obtained for him the rectory of Shipton near Salisbury; and he might have had considerable preferment, had he been willing to subscribe to the canons. He died in 1587, aged 70; and was buried in the chancel of St. Giles's, Cripplegate. He was a man of great industry, and considerable learning; a zealous, but not a violent reformer; a non-conformist, but not an enemy to the church of England. He left two sons; one of whom was bred a divine.

he other a physician. He wrote many pieces: but his principal work is, the Acts and Monuments of the Church, &c. commonly called Fox's Book of Martyrs.

FOX, CHARLES JAMES, one of the greatest statesmen in Europe, was the third son of Henry, the first Lord Holland, and Lady Georgiana Carolina Lenox, daughter of the late Duke of Richmond. He was born Jan. 24, 1749; and the union of his parents, conferred on him a descent from rival kings. To pourtray any thing like the character of this most distinguished senator, the limits of a volume would scarcely suffice. At the early period of nine years of age, the dawn appeared of that vast genius, which has since proved the admiration of the world; his father, who was a man of superior capacity, was then prime-minister; and having left in his study a political treaty which was for the approbation of a foreign power, Charles having eagerly perused it, threw the document into the fire, declaring it was unfit for the purpose intended. When about fifteen, he was permitted during the vacation month from college to visit the gay and luxurious city of Paris, but to return upon the expiration of that time; he immediately entered into all the gaiety of the scene which that capital affords with the ardour of a fashionable amateur; but quitted those fascinating attractions without reluctance, and once more returned to the seat of learning, where his industry was equally prominent: there it was observed, he had "no cotemporary so erudite in knowledge, none so elegant in mirth, and that to have seen him in either one or the other, it must have been supposed, that each was his peculiar study;" and from his fellow-student, the Earl of Carlisle, he received the following pleasing anticipation of his future abilities:—

How will my Fox alone, by strength of parts
Shake the loud senate, animate the hearts
Of fearful statesmen! while around you stand,
Both peers and commons, listening your command;
While Tully's sense its weight to you affords,
His nervous sweetness shall adorn your words:
What praise to Pitt, to Townshend, e'er was due,
In future times, my Fox, shall wait on you.

His father never suffered him to be contradicted, that his towering genius should follow its own bent. In 1768, about twelve months before he had attained his 21st year, he took his seat in parliament under the banners of the Minister, as representative of Midhurst, in Sussex; but soon quitted the Tory side, to join the animated standard of a Burke and Dunning, imbibing those Whig principles which produced that strong and lasting attachment to the British Constitution, that has immortalized his memory. Mr. Fox's coalition with Lord North for a long time obscured his political integrity, and occasioned him much obloquy. Power, it should seem, was never long in his possession; and the transcendent abilities of his great rival Mr. Pitt, placed him as the honorable leader of the Opposition for many years; and he was looked up to as the "Man of the People." His memorable bill upon the administration of affairs in India, which he introduced into the House of Commons on the 18th of November, 1783, drew from the celebrated Mr. Burke, the following high eulogium: "I must say, then, that it will be a distinction honorable to the age, that the rescue of the greatest number of the human race that ever were so grievously oppressed from the greatest tyranny that was ever exercised, has fallen to the lot of abilities and dispositions equal to the task; that it has fallen to one who had the enlargement to comprehend, the spirit to undertake, and the eloquence to support, so great a measure of hazardous benevolence. But he has put to hazard his ease, his security, his interest, his power, even his darling popularity, for the benefits of a people whom he has never seen. He has faults; but they are faults which though they may in a small degree tarnish the lustre, and sometimes impede the march, of his abilities, have nothing in them to extinguish the fire of great virtues. In those faults there is no mixture of deceit, of hypocrisy, of pride, of ferocity, of complexional despotism, nor a want of feeling for the distresses of mankind:" and again, in 1790, upon the Army Estimates, that illustrious man, after those wide and important differences of opinion had been observable, which dissolved the long and close connexion of those two celebrated persons; he thus expressed himself—"he wished, as among the greatest benefits he could wish the country, an eminent share of power to the Right Hon. Gentleman (Mr. Fox) because he knew that, to his great and masterly understanding he had joined the greatest possible share

of that natural moderation, which is the best corrective of power; that he was of the most open, artless, candid, and benevolent disposition; disinterested in the extreme; of a temper mild and pliable even to a fault; without one drop of gall in his whole composition." On Mr. Fox's avowing his intention of retiring from office, Mr. Pitt observed, "he could not think his retreat warrantable; and that his abilities marked him to be public property." No man ever received the stamp of public approbation more than he did; his fame travelled far before him; and if he was the particular object of attention in his own country, he was no less so in other nations. In Russia, Catherine the Great, animated by his lively interference to prevent a war, and improve the relation between the two countries, requested Mr. Fox to sit for a bust of white marble to be placed between those of Demosthenes and Cicero at Petersburg. During his tour through Switzerland, the peaceful natives of that once happy soil, those brave defenders of their liberties, came out for miles in myriads to behold this prodigy of a man, and hail this great champion in freedom's cause, which the elegant author of the "Decline and Fall of the Roman Empire," thus pleasingly describes:—"Mr. Fox (Sept. 1788) gave me two days of free and private society. He seemed to feel, and even to envy, the happiness of my situation; while I admired the powers of a superior man, as they are blended in his attractive character, with all the softness and simplicity of a child. Perhaps no human being was ever more perfectly exempt from the taint of malevolence, vanity, or falsehood." In France, (Sept. 1802,) when Mr. Fox was presented to the First Consul (Bonaparte), he publicly declared, "that he was extremely happy in having the honor of seeing a man, whose fame as a statesman filled all Europe; and in being the enlightened friend of peace and conciliation between the two countries." He had been through life the most intimate and confidential friend of the heir apparent to the crown; and on one particular occasion received the most heart-felt thanks from the king for that sound and constitutional advice he had given his son; his conversation, it should seem, had made a deep and lasting impression upon the mind of his royal highness, for on his late birth-day (1810) upon the health of his daughter being drank, he most eloquently expressed himself to the following effect: "that he had made it his first care to instil into the mind and heart of his daughter the knowledge and love of the true principles of the British Constitution; and he had pointed out to her young understanding, as a model for study, the political conduct of his most revered and lamented friend, Mr. Fox, who had asserted and maintained, with such transcendent force, the just principles upon which the government, under this excellent Constitution, ought to be administered for the true and solid dignity of the crown, and the real security, freedom, and happiness of the people." The French Revolution by its alarming progress struck a panic amongst the great men of this country, and Mr. Fox was deserted by many of his friends, but the secession of Mr. Burke affected him even to tears, and he candidly acknowledged in the House of Commons, "that during the conversation of only a twelvemonth with that distinguished senator, he had gained more useful knowledge, than by all his experience, learning, and books;" yet notwithstanding he remained inflexible in his opinions; and during the extraordinary convulsions of a neighbouring nation, and the political feuds and animosities that agitated this country; sedition at home, and mutiny in the fleet; a rebellion in Ireland, by whom he lost one of his dearest connections; the voting away the Irish parliament, and the measure of a Union—an era, the most difficult and dangerous for a leader to steer clear; but he preserved the true dignity of his great character, triumphed at length over his enemies, was sought as the land-mark for the nation to rally round, and once more (Jan. 31, 1806,) became the servant of his king. Unfortunately for the nation, he enjoyed this station but for a few months; when he was deprived of serving that country, the first and nearest object of his heart. Yet it must not be forgot that during that short period, the abolition of the Slave Trade, (the bill respecting which was introduced into parliament so long back as 1791,) was accomplished; a traffic so disgraceful to an enlightened and free people! His last scene was marked with fortitude and composure: in speaking to a friend who anxiously hung over his pillow, about the state of the soul after death, he observed, "It is immortal, I am convinced; the existence of the Deity is a proof that spirits exists, why not therefore the soul of man? and if such

an essence as the soul exists, by its nature it may exist for ever. I should have believed in the immortality of the soul, though Christianity had never existed; but how it acts as separated from the body is beyond my capacity of judgement. This however I shall know by next Christmas. I am happy, full of confidence, I may say of certainty; God's will be done! I have lived long enough, and shall die happy." He expired without a groan, on the 13th of September 1806, in the 58th year of his age, and was buried in Westminster Abbey on the 10th of October following, exactly opposite the monument of the illustrious Chatham; and within 18 inches of his political opponent Mr. Pitt. His funeral was splendid in the extreme, and attended by most of the distinguished characters in the kingdom; but the afflictions pouredtrayed by the people upon this public calamity, made a more lasting impression than all the magnificent paraphernalia of escutcheons, or the refined execution of the sculptor's art. With the sentiments of such men, who have been the leading features of society, little is left more than to observe, that as a statesman, it might be urged he was without a competitor, as his warnings proved almost prophetic; as a scholar, supremely distinguished; as a poet, harmony breathed through every line that found its way to the public; as a critic, profound, with a taste as refined as decisive; as a friend, disinterested; as an orator, though he might want the elegance of a Cicero, yet the powerful reasoning of a Demosthenes was conspicuous, simplicity was its characteristic, and his auditors never departed without being convinced of the truth of his arguments; in reply, he stood unequalled; as a literary character, his time was too much occupied to produce any thing more than a few political pamphlets, a small collection of poems, and a posthumous work, entitled, "A History of the early part of the Reign of James II." with an animated likeness of the author, engraved from a bust by Nollekens, under which the following lines appear, written by his most intimate friend, General Fitzpatrick:—

A Patriot's even course he steered,
Mid' Faction's wildest storms, unmoved;
By all, who mark'd his mind, revered,
By all, who knew his heart, beloved.

It was published, with an introductory chapter, under the direction of his nephew, Lord Holland; who has already given proofs of that classic excellence, which cannot fail of adding fresh laurels to this distinguished family. In short, his demise, has left in the political hemisphere an awful chasm; and the application of the poet was never more appositely quoted, than to "take him for all in all, we shall not look upon his like again!"

FOX, in zoology, an animal of the dog kind, which much resembles the common dog in form, and is of the size of a spaniel: it is chiefly distinguished by its long and straight tail, with the tip white. See CANIS.

FOXGLOVE, in botany. See DIGITALIS.

FOX ISLAND, an island in the Atlantic, on the west coast of Ireland; 7 miles E. of Slyme-head.

FOX ISLANDS, or LYSSIE OSTROVA, a group of 16 islands situated between the E. coast of Kamtschatka, and the W. coast of America. Lat. between 52° and 55° N.

FOY, St. a town of France, in the department of Lot and Garonne, 35 miles E. of Bourdeaux.

FOYLE, a river of Ireland in Derry, which runs by Londonderry, into Lough Foyle.

FOYLE, LOUGH, a large bay of Ireland; at the mouth of the Foyle, four miles below Londonderry.

FRACHES, in the glass trade, are the flat iron pans into which the glass vessels already formed are put when in the tower over the working furnace, and by means of which they are drawn out through the leers, that they may be taken gradually from the fire, and cooled by degrees.

FRACTION, in arithmetic and algebra, a part or division of an unit or integer; or a number which stands to an unit in the relation of a part to its whole. The word literally imports a broken number. Fractions are usually divided into decimal, sexagesimal, and vulgar. See ALGEBRA, and ARITHMETIC.

FRACTURE, in surgery, a rupture of a bone, or a solution of continuity in a bone, when it is crushed or broken by some external cause. See SURGERY.

FRENUM, or FRENUM, BRIDLE, in anatomy, a name given to divers ligaments, from their office in retaining and curbing the motions of the parts they are fitted to; as,

FRENUM LINGUE, or BRIDLE OF THE TONGUE, a membranous ligament, which ties the tongue to the os hyoides, larynx, fauces, and lower parts of the mouth.

FRAGA, a strong town of Spain in the kingdom of Arragon, 53 miles E. S. E. of Saragossa.

FRAGARIA, the STRAWBERRY, a genus of the polygynia order, and icosandria class of plants; natural order, Senticosæ. Calyx decemfid; petals five; receptacle of the seeds ovate, in the form of a berry. It has three species and several varieties.

FRAGNINO, and FRAGNITELLO, two towns of Naples, in the province of Principato Ultra; the former eight miles, and the latter six, from Benevento.

FRAGOA DE S. PEDRO, a town of Portugal, in the province of Beira; 13 miles S. S. W. of Lamego.

FRAIL, signifies 75 pounds of raisins.

FRAISE, in fortification, a kind of defence, consisting of pointed stakes, six or seven feet long, driven parallel to the horizon into the retrenchments of a camp, a half-moon, or the like, to prevent any approach or scalade. Fraises differ from palisades chiefly in this, that the latter stand perpendicular to the horizon, and the former jut out parallel to it, or nearly so, being usually made a little sloping, or with the points hanging down. Fraises are chiefly used in entrenchments and other works thrown up of earth; sometimes they are found under the parapet of a rampart, serving instead of the cordon of stone used in stone-works.

FRAISE A BATTALION, is to line the musqueteers round with pikes, that in case they should be charged with a body of horse, the pikes being presented may cover the soldiers from the shock, and serve as a barricade.

FRAME, a sort of loom, whereon artificers stretch their linens, silks, stuffs, &c. to be embroidered, quilted, or the like.

FRAME, among foundlers, a kind of ledge, which, being filled with wetted sand, serves as a mould to cast their works in. See FOUNDRY.

FRAME, in joinery, a kind of case, wherein a thing is set on closed, or even supported; as a window-frame, a picture-frame, &c.

FRAME, among painters, a kind of square, consisting of four long slips of wood joined together, whose intermediate space is divided by threads into several little squares like a net; and hence sometimes called reticula. It serves to reduce figures from great to small; or, on the contrary, to augment their size from small to great.

FRAME, among printers, is the stand which supports the cases.

FRAMLINGHAM, a large and ancient town of Suffolk, 18 miles N. E. of Ipswich, and 27 N. N. E. of London.

FRAMPTON, or FROMETON, a town of England, in Dorsetshire, 6 miles W. N. W. of Dorchester, and 12 N. W. of Weymouth.

FRANCAVILLA, the name of five towns of Naples.

FRANCE, an extensive country of Europe, for many ages a kingdom, but now one of the most powerful empires in the world. Before the present war, it was bounded by the English channel and the Austrian Netherlands on the N.; by Germany, the Alps, Switzerland, Savoy, and Piedmont, on the E.; by the Mediterranean sea and the Pyrenean mountains, which separate it from Spain, on the S.; and by the Atlantic ocean on the W. The air of France is pure, temperate, and healthy. It is so happily situated in the middle of the temperate zone, that some reckon it equal to Italy, both with regard to its fine landscapes and the fertility of the soil. The climate is undoubtedly much more salubrious. The soil produces corn, wine, oil, flax, fruits, &c. in great abundance. The monarchy was absolute before the revolution in 1789; and the subjects were extremely devoted to their prince, even under the greatest acts of oppression. The parliaments, for a long series of years past, had little or no share in the government; and their business was confined to the passing and registering the arrets or laws which the king sent them. However, they did not always pay a blind obedience to the king, and there have been frequent instances of their making a very spirited opposition. In civil causes they were the last resort, provided the court did not interpose. The parliament of Paris was the most considerable, where the king used often to come in person to see his royal acts recorded. It consisted of the dukes and peers of France, besides the ordinary members, who purchased their places; and they only took cognizance of causes belonging to the crown. The revenues

of the crown arose from the *taille* or land-tax, and the aids which proceeded from the customs and duties on all merchandize, except salt, the tax upon which commodity was called the *gabelles*. See *GABEL*. Besides these, there were other taxes, as, the capitation or poll-tax; the tenths of all estates, offices, and employments; besides the 15th penny, from which neither the nobility nor clergy were exempted; the tenths and free-gifts of the clergy, who were allowed to tax themselves; and, lastly, crown-rents, fines, and forfeitures, which brought in a considerable sum. All these are said to have amounted to 15,000,000*l.* sterling a-year. But the king had other resources and ways of raising money, whenever necessity obliged him. France was originally possessed by the Celtes or Gauls; a very warlike people, who often checked the progress of the Roman arms: nor did they yield till Julius Cæsar totally subdued their country, and reduced it to the form of a Roman province. In the reign of Valerian, the ancient Roman valour and discipline had begun to decline, and the neighbouring nations, began to make frequent incursions; and among the rest the Franks, a German nation, inhabiting the banks of the Rhine, proved particularly troublesome. After this period the country underwent various revolutions, but was more settled in the absolute monarchical form of government from the coronation of Charlemagne, till the late revolution in 1789, after which it became a republic. But the unparalleled successes of general Bonaparte induced him to take the reigns of government into his own hands; he was created first consul, Dec. 15, 1799, and afterwards assumed the title of emperor, May 20, 1804. France, before the revolution, was divided into the following military governments, or provinces: Alsace, Angoumois, Anjou, Armagnac, Artois, Aunis, Auvergne, Barrois, Basques, Bearn, Berry, Bigorre, Blaisois, Boulonnois, Bourbonnois, Bresse, Brittany, Burgundy, Cambresis, Champagne, Couserans, Dauphiny, Forez, Foix, Franche Comté, French Flanders, Gascony, Gevaudan, Guienne, French Hainault, Isle of France, Languedoc, Limosin, Lorrain, Lyonnois, Marche, Maine, Marsan, Navarre, Nivernois, Normandy, Orléanois, Perche, Perigord, Picardy, Poitou, Provence, Querci, Ruergue, Roussillon, Saintonge, Soissonnois, Touraine, Velay, and Vermandois. These varied much from each other in point of extent and importance, and there were others of still inferior consideration. France, in consequence of the revolution, was divided by the first legislative assembly into 83 departments, and these were subdivided into districts, cantons, and municipalities. The names of the departments are, Ain, Aisne, Allier, Alps Lower, Alps Upper, Ardeche, Ardennes, Arriege, Aube, Aude, Aveyron, Calvados, Cantal, Charente, Charente Lower, Cher, Correze, Corsica, Côte d'Or, Creuse, Dordogne, Doubs, Drome, Eure, Eure and Loire, Finisterre, Gard, Garonne Upper, Gers, Gironde, Herault, Indre, Indre and Loire, Isere, Ille and Vilaine, Jura, Landes, Loire and Cher, Loire Lower, Loire Upper, Lot, Lot, Lot and Garonne, Lozere, Maine, Maine and Loire, Manche, Marne, Marne Upper, Meurthe, Meuse, Morbihan, Moselle, Mouths of the Rhine, Nievre, Nord or North, North Coasts, Oise, Orne, Paris, Puy de Dome, Pyrenees Eastern, Pyrenees Lower, Pyrenees Upper, Rhine Lower, Rhine Upper, Rhone and Loire, Saone Upper, Saone and Loire, Sarne, Seine and Oise, Seine Lower, Seine and Marne, the Two Sevres, Somme, Straits of Calais, Tarn, Var, Vendee, Vienne, Vienne Upper, Vosges, and Yonne. About 18 new departments have been since erected out of the conquered territories. The chief mountains of France, are those of the Alps, Pyrenees, Cevennes, and Auvergne: Mount Blanc, &c. The population of France, before the revolution, was stated by the French at 25 millions; but from the great extent of territory acquired since the commencement of the present war, the total population is supposed to be now increased to more than 33 millions. Besides all the necessities of life, France produces many of its luxuries; as silk, perfumes, lemons, oranges, olives, prunes, peaches, &c. The forests abound with wood, and the mountains with mines of copper, lead, tin, iron; and some gold and silver. Gold in grains is also found among the sands of some rivers. The established religion of France, from the reign of Clovis I. to the revolution, has been the Roman Catholic; and though it was never accompanied by that dreadful engine of ecclesiastical tyranny, the inquisition, yet no country in Europe has exhibited more barbarous and bloody proofs of the intolerant spirit of that system of superstition than

France. Yet, though universal liberty of conscience was established upon the revolution in 1789, the Roman Catholic system was not attempted to be abolished. So far from this, the kingdom was divided into 10 archbishoprics (formerly 18), and 73 bishoprics (formerly 113), an episcopal hierarchy; an episcopal town being allotted to each department. But Danton and his atheistical associates, in the convention of 1793, endeavoured to overthrow all religion whatsoever. Upon the fall of Danton, Robespierre, affecting an abhorrence of the impiety of Atheism, did his utmost to recommend Deism, in its stead. But since his death, Christianity has been again openly professed; the churches have been restored to the use of all who incline to attend them; and people of all religious persuasions are allowed to worship God in the way most agreeable to themselves. France is watered and fertilized by a great number of rivers, many of which afford names to the new departments. The principal of these are the Seine, Loire, Garonne, and Rhone. The French in time of peace carry on a great trade with Spain, Italy, and the East Indies. Before the war, a trade very advantageous to Britain was established by the Commercial Treaty. They have very extensive manufactures of linens, woollens, silks, laces, paper, china, soap, &c. and particularly what is called Castile soap. France before the war, was said to contain 400 cities or walled towns, and 43,000 small towns and villages. Paris is the capital.

FRANCE, ISLE OF, a late province of France, so called, because it was formerly bounded by the rivers Seine, Marne, Oise, Aisne, and Ourque. It comprehended the Beauvoisis, the Valois, the county of Senlis, the Vexin, the Hurepois, the Gatinois, the Multien, the Goele, and the Mantois. Paris was the capital. It is now divided into four departments; viz. Oise, Seine and Oise, Seine and Marne, and Paris.

FRANCE, ISLE OF, or MAURITIUS, an island in the Indian Ocean. See *MAURITIUS*.

FRANCFORT ON THE MAINE, an Imperial and Hanseatic town of Germany, in Franconia, where the emperors were formerly elected. It is a handsome, strong, and rich place, and has a great deal of commerce. It is 20 miles E. of Mentz, and 350 W. by N. of Vienna. Lon. 8° 35' 40" E. Lat. 50° 7' 40" N.

FRANCFORT ON THE ODER, a town of Germany, in the middle Marche of Brandenburg, 43 miles S. E. of Berlin. Lon. 14. 45. E. Lat. 52. 22. N.

FRANCHE COMPTE, a late province of France, bounded on the S. by Bresse; on the W. by Burgundy; on the N. by Lorraine; and on the E. by Alsace and Switzerland. It is now divided into three departments; viz. Doubs, Jura, and Upper Saone.

FRANCHEMONT, or FRANCHIMONT, a town and district of Germany, in the late bishopric of Liege; now included in France, in the department of Ourte.

FRANCHISE and LIBERTY, in law, are used as synonymous terms; for "a royal privilege, or branch of the king's prerogative, subsisting in the hands of a subject." Being therefore derived from the crown, they must arise from the king's grant; or, in some cases, may be held by prescription, which presupposes a grant. The kinds are numerous and various. We shall briefly mention some of the principal; premising only, that they may be vested either in natural persons or bodies politic; in one man, or in many: but the same identical franchise, that has before been granted to one, cannot be bestowed on another, for that would prejudice the former grant. A County Palatine is a franchise vested in several persons. It is likewise a franchise for a number of persons to be incorporated and subsist as a body politic; with a power to maintain perpetual succession, and do other corporate acts: and each individual member of such corporation is also said to have a franchise. Other franchises are to hold a court-leet; to have a manor or lordship; or, at least, to have a lordship paramount: to have waifs, wrecks, estrays, treasure-trove, royal fish, forfeitures, and deodands: to have a court of one's own, or liberty of holding pleas and trying causes: to have cognizance of pleas; which is a still greater liberty, being an exclusive right, so that no other court shall try causes arising within that jurisdiction: to have a bailiwick, or liberty exempt from the sheriff of the county; wherein the grantee only, and his officers, are to execute all processes: to have a fair or market: with the right of taking toll, either there or at any other public places, as at bridges, wharfs,

wharfs, or the like; which tolls must have a reasonable cause of commencement, (as in consideration of repairs, or the like,) else the franchise is illegal and void: or lastly, to have a forest, chase, park, warren, or fishery, endowed with privileges of royalty. See CHASE, FOREST, &c.

FRANCHISE is also used for an asylum or sanctuary, where people are secure of their persons, &c. Churches and monasteries in Spain are franchises for criminals; so were they anciently in England, till they were abused to such a degree that there was a necessity for abolishing the custom.

FRANCHISE OF QUARTERS is a certain space or district at Rome, wherein are the houses of the ambassadors of the princes of Europe; and where such as retire cannot be arrested or seized, nor prosecuted at law.

FRANCIS, St. the founder of the society of the Franciscans, was the son of a merchant of Assisi, in the province of Umbria. Having led a dissolute life, he was reclaimed by a fit of sickness, and afterwards fell into an extravagant kind of devotion, that looked less like religion than alieation of mind. In 1208, hearing the passage quoted, (Matt. x. 9, 10,) "Provide neither gold nor silver," &c. he was led to consider a voluntary and absolute poverty as the essence of the gospel, and to prescribe it as a sacred rule to himself and those who followed him. See FRANCISCANS. He died in 1226.

FRANCISCANS, in ecclesiastical history, religious of the order of St. Francis, founded by him in 1209. This society, which appeared to Innocent III. extremely adapted to the state of the church, was solemnly approved and confirmed by Honorius III. in 1223. Francis, through an excessive humility, would not suffer the monks of his order to be called *fratres*, i. e. brethren or friars, but *Fraterculi*, i. e. little brethren, or friars minor, by which denomination they still continue to be distinguished. They are also called grey friars, on account of the colour of their clothing, and Cordeliers, &c. The Franciscans and Dominicans were zealous and active friends to the papal hierarchy. In 1287, Matthew of Aqua Sparta, being elected general of the order, discouraged the ancient discipline of the Franciscans, and indulged his monks in abandoning even the appearance of poverty. This conduct raised the indignation of the spiritual or austere Franciscans; so that from 1290, schisms arose in an order that had been famous for its pretended disinterestedness and humility. Such was the enthusiastic frenzy of the Franciscans, that they impiously maintained, that St. Francis was a second Christ, in all respects similar to the first; and that their institution and discipline were the true gospel of Jesus. Accordingly, Albizi, a Franciscan of Pisa, published a book in 1383, with the applause of his order, intitled, "The Book of the Conformities of St. Francis with Jesus Christ!" In the beginning of the 18th century, the whole Franciscan order was divided into two parties; the one called Spirituals, who embraced the severe discipline and absolute poverty of St. Francis; and the other, Brethren of the Community, who insisted on mitigating the austere injunctions of their founder.

FRANCOIS, CAPE, a town in the N. part of Hispaniola. Lon. 72. 18. W. Lat. 19. 46. N.

FRANCOISE, a town of France, in the department of Lot, $7\frac{1}{2}$ miles N. W. of Montauban, and 20 $\frac{1}{2}$ S. S. W. of Cahors.

FRANCONIA, a circle of Germany, bounded on the N. by Meissen and Thuringia, on the S. by Bavaria and Suabia; on the E. by Bohemia and the Upper Palatinate, and on the W. by the Lower, and the electorate of Mentz; being 88 miles from N. to S. and 95 from E. to W. The middle is very fertile in corn, wine, and fruits; but the borders are full of woods and barren mountains. The majority of the people are Lutherans; but there are also many Calvinists, Roman Catholics, and Jews. The Franks, who conquered and gave name to France, came from this province. Nuremberg is the capital.

FRANEKER, FRANEQUER, or FRANKER, a town of France, in the department of Eems, and late province of North Friesland, 9 miles W. of Lewarden.

FRANK, or FRANC, in the ancient English customs, signifies literally free from charges and impositions, or exempt from public taxes: it is used in various senses; sometimes compounded, and sometimes not; though the latter is doubtless most proper. Thus,

FRANK ALMOIGNE is a tenure, whereby a religious corporation, aggregate or sole, holdeth lands of the donor to them and

their successors for ever. The service which they were bound to render for these lands was not defined: but only in general to pray for the souls of the donor and his heirs, dead or alive; and therefore they did no fealty (which was incident to all other services,) because this divine service was of a more exalted nature. This is the tenure by which almost all the ancient monasteries and religious houses held their lands; and by which the parochial clergy, and very many ecclesiastical and eleemosynary foundations, still hold them; the nature of the service being upon the reformation altered, and made conformable to the purer doctrines of the church of England. It was an old Saxon tenure; and continued under the Norman revolution, through the great respect that was shewn to religion and religious men in ancient times. This is also the reason that tenants in frankalmoigne were discharged of all other services except the *trinoda necessitas*, of repairing the highways, building castles, and repelling invasions; just as the druids, among the ancient Britons, had "*omnium rerum immunitatem*." And even at present this is a tenure of a very different nature from all others; being not in the least feudal, but merely spiritual. For, if the service be neglected, the law gives no remedy by distress, or otherwise, to the lord of whom the lands are holden; but merely a complaint to the ordinary or visitor to correct it.

2. FRANK CHACE is a liberty of free chase, whereby persons that have lands within the compass of the same, are prohibited to cut down any woods, &c. out of the view of the forester.

3. FRANK FEE signifies the same thing as holding lands and tenements in fee simple; that is, to any person and his heirs, and not by such service as is required by ancient demesne, but is pleaded at common law. See FEE.

FRANK LAW, the free and common law of the land, or the benefit a person has by it. He that for any offence loseth this frank law incurs the inconveniences which the law affords.

FRANK MARRIAGE, in law, is where tenements are given by one man to another, together with a wife, who is the daughter or cousin to the donor, to hold in frank marriage. By such gift, though nothing but frank marriage is expressed, the donees shall have the tenements to them, and the heirs of their two bodies begotten; that is, they are tenants in special tail.

FRANKPLEDGE, a pledge or surety for freemen. For the ancient custom of England, for the preservation of the public peace, was that every freeborn man at 14 years of age, religious persons, clerks, knights and their eldest sons excepted, should find security for his fidelity to the king, or else be kept in prison: whence it became customary for a certain number of neighbours to be bound for one another, to see each man of their pledge forthcoming at all times, or to answer the transgression of any one absenting himself. This was called frankpledge, and the circuit thereof was called decenna, because it commonly consisted of ten households; and every particular person, thus mutually bound, was called decennier.

FRANK, or FRANC, an ancient coin, either of gold or silver, struck and current in France. The value of the gold frank was somewhat more than that of the gold crown; the silver frank was a third of the gold one: this coin is long out of use, though the term is still retained as the name of a money of account; in which sense it is equivalent to the *livre*, or twenty sols.

FRANK LANGUAGE, or *LINGUA FRANCA*, a kind of jargon spoken on the Mediterranean, and particularly throughout the coasts and ports of the Levant, composed of Italian, Spanish, French, vulgar Greek, and other languages.

FRANKED LETTERS. The privilege of letters coming free of postage to and from members of parliament was claimed by the House of Commons in 1660, when the first legal settlement of the present post-office was made; but afterwards dropped, upon a private assurance from the crown, that this privilege should be allowed the members. Accordingly a warrant was constantly issued to the postmaster-general, directing the allowance thereof to the extent of two ounces in weight: till at length it was expressly confirmed by 4 Geo. III. c. 24, which added many new regulations, rendered necessary by the great abuses in franking: whereby the annual amount of franked letters had increased from 23,600l. in the year 1715, to 170,700l. in the year 1763. Other regulations afterwards took place; in particular, franks were required to be dated (the month written at length,) and put into the office the same day; notwithstanding which, the revenue still lost

by this privilege above 80,000*l.* per annum. The following are the regulations of franking required by 25 Geo. III. and now in force. No letter directed by or to any M. P. shall be exempted from postage if it exceeds one ounce in weight. No letter directed by any member shall be exempted, unless he shall actually be in the post-town, or within the limits of its delivery of letters, or within 20 miles of it on the day, or the day before it, on which the letter shall be put into the office. No member shall be entitled to send free from postage more than ten letters in one day, nor to receive more than 15. Whenever the number of letters sent or received by such member in one day shall exceed the number exempted, and the postage upon any of them shall differ, the letters chargeable with a higher postage shall be included in the number exempted, in preference to any chargeable with a lower postage, and the remainder shall be chargeable with the postage to which common letters are now chargeable. Persons who may now in right of their offices send and receive letters free may continue so to do.

FRANKENDAL, a strong town of Germany, now included in France, in the department of Mont Tonnerre, 8 miles N. W. of Mannheim, and 8 S. of Worms. Lon. 8. 29. E. Lat. 49. 25. N.

FRANKENIA, in botany, a genus of the monogynia order, and hexandria class of plants; natural order, Calycanthemæ. Calyx quinquefid, funnel-shaped; petals five; stigma sexpartite; capsule unilocular and trivalvular. It has three species.

FRANKENSTEIN, a town of France, in the department of Sarre and Moselle, 20 miles S. E. of Deux Ponts.

FRANKFORD, a town of Virginia, the capital of Pendleton county, 180 miles N. W. of Richmond.

FRANKFORT, a town of the United States, on the river and in the state of Kentucky.

FRANKINCENSE, is a gummy resin, the product of the *juniperus lycia*, consisting of equal parts of gum and resin; the first is soluble in water, the other in alcohol. It is brought from Turkey and the East Indies, but is principally collected in Arabia. It usually comes to us in drops, but in a very impure state, a hundred pounds not yielding more than from forty to fifty pounds of pure frankincense.

FRANKLAND'S ISLANDS, a cluster of islands in the South Sea; 6 miles from the N. E. coast of New Holland. Lon. 146. 0. E. Lat. 17. 13. S.

FRANKLIN, BENJAMIN, LL. D. and F. R. S. one of the most celebrated philosophers and politicians of the 18th century, was born at Boston, 6th Jan. 1706. He was the son of Josias Franklin, a tallow-chandler, descended from an ancient English family, who had resided upwards of three centuries at Eaton in Northamptonshire, possessing a small freehold estate of 30 acres. Benjamin was placed under him; but a difference happening between them, he removed to New York, from whence he went to Philadelphia, where after serving as a journeyman some time, he attracted the notice of Sir William Keith, the governor, who persuaded him to set up for himself. Accordingly he came to England to procure printing materials, but on his arrival he found that the governor had deceived him by false promises, on which he worked as a journeyman printer in London, and in 1726 returned to Philadelphia, where he became clerk to a merchant. He next entered into partnership with a person named Meredith, in the printing-business, which he afterwards conducted alone. In 1730 he was united to a widow lady, whom he had courted before her first marriage. About this period he contributed to the forming of the public library at Philadelphia, and in 1732 he published his "Poor Richard's Almanack," in which he inserted some useful aphorisms or maxims of prudence. In 1736 he was appointed clerk to the general assembly at Pennsylvania, and the year following post-master of Philadelphia. In the French war in 1744 he proposed and carried into effect a plan of association for the defence of that province. About this time he commenced his electrical experiments of which he published an account. He had the honour of making several discoveries in this branch of philosophy, the principal of which was the identity of the electric fire and lightning. In 1747 he was chosen a representative of the general assembly, in which situation he distinguished himself by several acts of public utility. By his means a militia bill was passed, and he was appointed colonel of the Philadelphia regiment. In 1757 he was sent to England as agent for Pennsylvania. At

this time he was chosen fellow of the Royal Society, and honoured with the degree of doctor of laws by the universities of St. Andrews, Edinburgh, and Oxford. In 1762 he returned to America, but two years afterwards he again visited England, in his former capacity as agent, and it was at this period that he was examined at the bar of the house of commons concerning the stamp act. In 1773 he returned home, and was elected a delegate to the congress. He was very active in the contest between England and the colonies, and was sent to France, where in 1778 he signed a treaty of alliance offensive and defensive, which produced a war between that country and England. In 1783 he signed the definitive treaty of peace, and in 1785 returned to America, where he was chosen president of the supreme council. He died in 1790. Besides his political, miscellaneous, and philosophical pieces published in 4to. and 8vo. he wrote several papers in the American Transactions, and two volumes of Essays, with his life prefixed, written by himself, 2 vols. 12mo. The following epitaph on himself was written by Dr. Franklin many years before his death:

The Body of
BENJAMIN FRANKLIN, PRINTER,
Like the cover of an old book,
Its contents torn out,
And stript of its lettering and gilding,
Lies here food for worms.
Yet the work itself shall not be lost;
For it will (as he believed) appear once more,
In a new and more beautiful edition,
Corrected and amended
By the AUTHOR.

FRANKLIN, a county of Georgia, in the Upper District, seated on the Tugulo.

FRANKLIN, a populous and well-cultivated county of Kentucky. Frankfort is the capital.

FRANKLIN, a county of North Carolina, in-Halifax district.

FRANKLIN, a fertile county of Pennsylvania. Chambersburg is the capital.

FRANKLIN, a county of Vermont, containing twenty townships.

FRANKLIN, a county of Virginia.

FRANKS, FRANCES, FRANKIS, or FRANQUIS, a name which the Turks, Arabs, Greeks, &c. give to all the people of the western parts of Europe. The appellation is commonly supposed to have had its rise in Asia, at the time of the croisades; when the French made the most considerable figure among the croisces: from which time the Turks, Saracens, Greeks, Abyssinians, &c. used it as a common term for all the Christians of Europe, and called Europe itself Frankistan. Du Cange says, that about the time of Charlemagne, they distinguished Eastern France, Western France, Latin or Roman France, and German France, which was the ancient France afterwards called Franconia.

FRANZBURG, a town of Upper Saxony, in Swedish Pomerania, 14 miles S. of Stralsund.

FRAPPING, in naval affairs, the act of crossing and drawing together the several parts of the tackle, or other complication of ropes, which had been already strained to their utmost extent; in this sense it resembles the operation of bracing a drum. The frapping increases tension, and consequently adds to the security acquired by the purchase.

FRASERBURGH, or FRASERSBURGH, a small sea-port town in Aberdeenshire, seated on the S. extremity of the Murray Frith, called Kinnaird's Head, 16 miles E. of Banff, and 40 N. of Aberdeen.

FRATERNAL AFFECTION is the love and attachment subsisting among, or due to one another by, children of the same family. A hearty benevolence, an ardent concern for each other's welfare, and a readiness to serve and promote it, are the peculiar offices of this relation.

FRATERNITY, in the Roman Catholic system, signifies a society for the improvement of devotion. Of these there are several sorts; as, 1. The fraternity of the rosary, founded by St. Dominic. It is divided into two branches, called the common rosary, and the perpetual rosary; the former of whom are obliged to confess and communicate every first Sunday in the month, and the latter to repeat the rosary continually. 2. The fraternity of the scapulary, whom the blessed Virgin, according to the sabbatine bull of pope John XXII. has promised to deliver out of hell

the first Sunday after their death. 3. The fraternity of St. Francis's girdle are clothed with a sack of a grey colour, which they tie with a cord; and in processions walk bare-footed, carrying in their hands a wooden cross. 4. That of St. Austin's leathern girdle comprehends many devotees. Italy, Spain, and Portugal, are the countries where the greatest number of these fraternities, some of which assume the name of arch-fraternities, are to be found. Pope Clement VII. instituted the arch-fraternity of charity, which distributes bread every Sunday among the poor, and gives portions to forty poor girls on the feast of St. Jerome their patron. 5. The fraternity of death buries such dead as are abandoned by their relations, and causes masses to be celebrated for them.

FRATRIAGE, the partition among brothers or coheirs, coming to the same inheritance or succession. It more particularly signifies a younger brother's inheritance; or whatever the younger sons possess of the father's estate, which, in our ancient law, they are said to enjoy *ratione fratrii*; and were to do homage for the same to the elder brother, he being bound to do homage to the superior lord for the whole.

FRATRICELLI, or **FRATELLI**, [Ital. *q. d. fraterculi*, little brothers,] in ecclesiastical history, an enthusiastic sect of Franciscans, which rose in Italy, particularly in Ancona, about A. D. 1294. The word was used as a term of derision, as they were most of them apostate monks. For this reason the term, as a nick-name, was given to many other sects, as the Catharists, Waldenses, &c. however different in their opinions and in their conduct. But this denomination, applied to the austere part of the Franciscans, was considered as honourable.

FRAUD, in law, signifies deceit in grants, or conveyances of lands, &c. or in bargains and sales of goods, &c. to the damage of another person. A fraudulent conveyance of lands or goods, to deceive creditors, as to creditors is void in law. And a fraudulent conveyance, to defraud purchasers, is also to such purchasers void; and the persons justifying, or putting off such grants as good, shall forfeit a year's value of lands, and the full value of the goods and chattels, and likewise shall be imprisoned.

FRAUENBOURG, a town of Prussia Royal, in Poland, on the river Frisch-haff, six or seven leagues from Elbing, to the N. E.

FRAUENFELD, a town of the Helvetic republic, the capital of the late bailiwick of Thurgau. It lies 20 miles N. E. of Zurich.

FRAUSTADT, a town of Silesia, on the frontiers of Poland, 70 miles N. W. of Breslau.

FRAUSTADT, or **WSCHOWA**, a town of Poland, on the frontiers of Silesia, 48 miles W. of Posen.

FRAXINELLA, in botany. See **DICTAMNUS**.

FRAXINUS, the **ASH**: a genus of the diœcia order, and polygamia class of plants; natural order, Sepiaria. Hermaphrodite; calyx none, or four-parted; corolla none, or four-petaled; stamens two; pistil one; seed or capsule one, lanceolate. There are four species. If a wood of these trees be rightly managed, it will turn out greatly to the advantage of the owner: for, by the underwood, which will be fit to cut every eight or ten years, there will be a continual income, more than sufficient to pay the rent of the ground and all other charges; and still there will be a stock preserved for timber, which in a few years will be worth 40s. or 50s. per tree. This tree flourishes best in groves, but grows very well in rich soil in open fields. It bears transplanting and lopping. In Lancashire they lop the tops of these trees to feed the cattle in autumn when the grass is on the decline; the cattle peeling off the bark as food. The wood has the singular property of being nearly as good when young as when old. It is hard and tough, and is much used to make the tools employed in husbandry. The ashes of the wood afford very good potash. The bark is used in tanning calf-skin. The season for felling this tree, is from November to February; for if cut down too early, or too late, it is liable to the worm. The ash is hurtful to corn-lands, and therefore should be planted either in hedges or clumps, at about nine or ten feet distance.

FREA, or **FRIGGA**, the wife of Odin, or Woden, was, next to him, the most revered divinity among the Heathen Saxons, Danes, and other northern nations. As Odin was believed to be father, Frea was esteemed the mother of all the other gods.

In the earliest times, Frea was the same with the goddess Herthus, or Earth, who was so devoutly worshipped by the Angli and other German nations. But when Odin, the conqueror of the north, usurped the honours due only to the true Odin, his wife Frea usurped those which had been formerly paid to mother Earth. She was worshipped as the goddess of love and pleasure, who bestowed on her votaries a variety of delights, particularly happy marriages and easy births. To Frea the sixth day of the week was consecrated, which still bears her name, Friday, or Frea's day.

FREAM, in husbandry, ploughed land worn out of heart, and laid fallow till it recover.

FRECKLES, **LENTIGINES**, are spots of a yellowish colour, of the bigness of a lentile seed, scattered over the face, neck, and hands. Freckles are either natural, or proceed from the jaundice, or the action of the sun upon the part. Heat, or a sudden change of weather, will often make the skin appear of a darker colour than is natural, and thereby produce what is called tan, sunburn, and morpew; which seem to differ only in degree, and usually disappear in winter. Persons of a fine complexion, and those whose hair is red, are most subject to freckles, especially in parts exposed to the sun and air. To remove freckles, put juice of lemons in a glass vial, and, mixing it with sugar and borax finely powdered, let it digest eight days, and then use it. According to Homburg, one of the best applications for dispersing freckles, is a mixture of bullock's gall with a solution of alum, which, after the latter has subsided, must be digested in the sun for three or four months in a close phial. Another preparation is made by taking four ounces of lemon-juice, and mixing with it two drachms of sugar, and one of borax, finely powdered; and, after these ingredients have stood a week or fortnight in a glass bottle, the liquor will be fit for use. As, however, freckles generally vanish during the winter, and have been observed to re-appear in early spring, the sharp morning-air of which, though salubrious, is said to be uncommonly favourable to their re-production, perhaps the most easy method of preventing them would be a careful attention to this circumstance.

FREDBERG, or **FREDEBERG**, a rich and strong town of Germany, in Misnia, on the river Multa.

FREDEBURG, or **FREDENBURG**, a town of Germany, in Westphalia, 52 miles E. of Cologne, and 50 W. of Cassel.

FREDERICA, a town of Georgia, on the island of St. Simons. Lon. 81. 25. W. Lat. 31. 0. N.

FREDERICIA, a strong sea-port town of Denmark, in North Jutland, seated on the Little Belt. Lon. 9. 4. E. Lat. 55. 37. N.

FREDERICK, the name of several European monarchs.

FREDERICK I., king of Prussia, the son of Frederick-William the Great, elector of Brandenburg, was born in 1657; and succeeded his father in the electorate, A. D. 1688. In 1700, he entered into a negotiation with the emperor, Leopold I., to get Prussia erected into a kingdom: which he at last obtained by a singular accident. While appearances were rather unpromising, he received a letter from his minister written in ciphers, advising him to use the interest of a certain prince; but, he mistaking the ciphers, applied to the emperor's confessor; who, being a Jesuit, was so much struck with the honour done him by a Protestant elector, that he exerted his whole interest, and that of his order, to procure him the desired object. Frederick was accordingly crowned king of Prussia, Jan. 18, 1701. He was endued with many virtues. He was magnificent, generous, constant to his marriage-vows, and studied the true interest of his subjects, by preserving his dominions in peace. He was three times married: his second queen was sister to king George I. He founded the university of Halle, and the royal academy at Berlin. He died in 1713.

FREDERICK II. surnamed the **GREAT**, king of Prussia, one of the greatest warriors the present age has produced, was the son of Frederick-William, then hereditary prince of Brandenburg, and princess Sophia Dorothea, daughter of king George I. He was born in 1712, the year before his father mounted the throne, who was so far from being a patron of literature, that he regarded nothing but what related to the military art; and most of his generals scarce knew how to sign their names. He obtained but a scanty education, owing to his father's contempt of letters and predilection for military discipline. On growing up, the young prince

prince shewed so strong an inclination to literature and music as to incur his father's displeasure. The severe treatment he received, led him, in 1730, to attempt an escape from Prussia, but the scheme being discovered, the prince was confined in the castle of Custrin, and his young companion Katte executed before his face. After a confinement of some months he obtained his pardon, and in 1733 married the princess of Brunswick Wolfenbüttele, in obedience to his father's command, but he never cohabited with her. In 1740 he succeeded to the throne, and taking advantage of the defenceless state of Maria-Theresa, queen of Hungary, he marched into Silesia, which was added to his dominions by the treaty of Breslaw. In 1744 the war was renewed against the queen of Hungary, and the same year Frederick took Prague, which however he was forced to quit by the approach of a Saxon army under the prince of Lorraine. In 1745 he defeated that prince, at Friedburgh, and then marched into Bohemia, where he defeated an Austrian army which was superior to his own. Shortly after he took Dresden and laid it under heavy exactions. A treaty of peace was concluded at the end of this year by the mediation of the English minister; and the interval of tranquillity was employed by Frederick in regulating his dominions, forming a body of laws, and in composing some literary works. In 1750 Voltaire visited Prussia, and was received with the most flattering marks of attention by the king; but the friendship at last ended in a violent quarrel, and the French philosopher quitted Prussia abruptly, and in disgrace. In 1756 a treaty was concluded between England and Prussia, which produced another between France, Austria, and Russia. The seven years war, as it is called, began by the march of Frederick into Saxony and taking the camp of Pirna. The following year he gained the battle of Prague over the Austrians, on which he laid siege to that city; but after reducing it to great straits, he was compelled to retreat by marshal Daun, and retire into Saxony. Frederick was now surrounded by enemies, the French entered Hanover, the Russians and Swedes advanced towards Prussia, and the Imperialists pursued him into Saxony. Still undaunted, he attacked and defeated the French and Austrians at Rosebach; then marching into Silesia, he beat another army at Lissa. The Russians and Swedes retreated precipitately from Prussia; and the Hanoverians took the field under the prince of Brunswick. In 1758 he received a large subsidy from England; and the same year he entered Moravia, where he laid siege to Olmutz, which was relieved by marshal Daun. He then marched against the Russians, who had laid siege to Custrin, and defeated them after a bloody battle at Zorndoff. But not long after he was surprized and beat by Daun, at Hockkirchen. The next year the king was defeated after a very obstinate and doubtful engagement, at Cunnnersdoff, by the Russians; and in 1761, the confederates entered Brandenburg, and took Berlin. Frederick, however, by defeating Daun at Torgau, gave a turn to his affairs, and the Russians and Swedes quitted his territories. In 1762 peace was restored between him and Russia and Sweden, and in 1763 a treaty much in his favour was concluded with the empress queen, by which Silesia was confirmed to Prussia. Still intent upon aggrandisement, he planned the partition of Poland in 1772, and obtained for his share Western Prussia. In 1778 he opposed the design of the emperor Joseph to dismember Bavaria, and marched in person against that monarch, who was assisted by the famous general Laudohn. But no action took place, and by the treaty of Teschen, in 1779, the Austrian court renounced the design. After a long and active life, Frederick died in 1786. He was courteous in his manners, lively in conversation, an acute politician, and in general fond of justice and humanity. But he was an avowed infidel, and actuated by no better principle than pleasure and self-interest. He never had any issue. His works published in his lifetime are in four vols. 8vo.; and since his death fifteen more have been printed. The principal are, the *Memoirs of the House of Brandenburg*: a poem on the *Art of War*: the *History of his own Time*: and the *History of the Seven Years War*.

FREDERICK V. king of Denmark, reigned 20 years, and on his death-bed, expressed his satisfaction to his son Christian VII. in a circumstance, which few monarchs can boast who have reigned so long. "It is a great consolation to me my son, (said he) in my last moments, that I have not injured any person, and that my hands are not stained with one drop of blood."

FREDERICK, a county of Maryland, bounded on the N. by

Pennsylvania, E. by Baltimore, S. W. by the Potomac, and W. by Washington.

FREDERICK, a county of Virginia, bounded on the N. by Berkley, E. and S. by the Shanandoah, and W. by Hampshire. Winchester is the chief town.

FREDERICK, a town of New Brunswick, on the N. side of St. John's river. Lon. 66. 45. W. Lat. 46. 3. N.

FREDERICKSBURG, a Danish fort on the Gold coast of Guinea, in Africa, near Cape Threepoints, 62 miles from Cape Coast Castle. Lon. 1. 5. W. Lat. 4. 30. N.

FREDERICKSBURG, a town of Virginia, in Spotsylvania county, 50 miles S. S. W. of Alexandria. Lon. 77. 26. W. Lat. 38. 22. N.

FREDERICKSHALL, a town of Norway in the province of Aggerhuys, on the frontiers of Sweden, and on the extremity of the Swinesund, 31 miles S. E. of Christiania, and 50 N. of Uddevalla. Lon. 10. 59. E. Lat. 59. 2. N.

FREDERICKSODE, a town of Denmark, in Jutland, 50 miles N. of Sleswick.

FREDERICKS-SUND, a sea-port of Denmark, in the isle of Zealand, 10 miles N. W. of Copenhagen. Lon. 12. 13. E. Lat. 55. 50. N.

FREDERICKSTADT, a town of Denmark, 17 miles W. S. W. of Sleswick.

FREDERICKSTADT, a town of Norway, in the province of Aggerhuys, 26 miles W. of Frederickshall.

FREDERICKSTOWN, a flourishing town of Maryland, 47 miles W. by N. of Baltimore.

FREE, or **IMPERIAL CITIES** in the late German constitution, are those not subject to any particular prince; but governed, like republics, by their own magistrates.

FREE-BENCH, signifies that estate in copyhold which the wife, being espoused a virgin, has after the decease of her husband for her dower, according to the custom of the manor. In regard to this free-bench, different manors have different customs. In the manor of E. and W. Enbourne in Berkshire, and other parts of England, there is a custom, that when a copyhold tenant dies, the widow shall have her free-bench in all the deceased husband's lands, dum sola & casta fuerit, "whilst she lives single and chaste;" but if she shall be guilty of incontinency, he shall forfeit her estate. Nevertheless, upon her coming into the court of the manor riding backwards on a black ram, with his tail in her hand, rehearsing a ridiculous and indelicate form of words in doggerel rhymes, characteristic of the times in which they were composed, the steward is bound by the custom to restore her to her free-bench.

FREEBOOTER, or **FLIBUSTER**, was originally a name given to the pirates who scoured the American Seas, and made war against the Spaniards.

FREED-MAN. See **LIBERTUS**.

FREEDOM. See **LIBERTY**.

FREEDOM OF CONSCIENCE. See **TOLERATION**.

FREEDOM OF THE WILL, that power or faculty of the mind, whereby it is capable of acting or not acting, choosing or rejecting whatever it judges proper or improper. Of this every man must be sensible, who finds in himself a power to begin or forbear, continue or end, several actions, barely by a thought or preference of the mind. See **METAPHYSICS**.

FREE-HOLD, signifies lands or tenements which a person holds in fee-simple, fee-tail, or for term of life. Freehold is distinguished into freehold in deed, and freehold in law: the first of which signifies the real possession of lands, &c. in fee, or for life; the other is the right that a person has to such lands or tenements before his entry.

FREE-HOLD is also extended to such offices as a man holds in fee, or during life. A freehold, by the common law, cannot commence in futuro, but it must take effect presently, either in possession or reversion, or remainder; and where a person pleads liberum tenementum, or freehold, generally the law intends he has an estate in fee, and not barely for life. Whatever is part of the freehold, goes to the heir; and things fixed thereto, may not be taken as a distress for rent, or in execution, &c. No man shall be disseised of his freehold by stat. Magna Charta, cap. 29, but by judgement of his peers, or according to laws of the land: nor shall any distrain freeholders to answer for their freehold, in any thing concerning the same, without the king's writ. Freehold estates,

estates, of certain value, are required by statutes to qualify jurors, electors of the knights of the shire in parliament, &c.

FREEMAN, SUSANNAN, afterwards Mrs. CARROL and Mrs. CENTLIVRE, a celebrated comic writer, daughter of Mr. Freeman of Holbeach, in Lincolnshire. She had such an early turn for poetry, that it is said she wrote a song before she was seven years old. Before she was twelve, she could not only read Moliere in French, but enter into the spirit of all the characters. Her father dying, left her to the care of a step-mother, whose treatment being harsh, she determined, though almost destitute of every necessary, to go up to London to seek a better fortune. As she was proceeding on foot, she was met by the noted libertine, Anthony Hammond, Esq. who was so struck with her beauty, that he instantly fell in love with her; and inquiring into her story, soon prevailed upon her inexperienced innocence to go with him to Cambridge. After some months' cohabitation, he persuaded her to come to London; where, in a short time, she was married to a nephew of Sir Stephen Fox. But he dying about a year after, her wit and beauty soon procured her a second husband, one Carrol, an officer in the army; but he being killed in a duel about eighteen months after, she became a votary of the Muses, and under this name of Carrol, some of her earlier pieces were published. Her first attempt was a tragedy, the *Perjured Husband*; but her natural vivacity leading her to comedy, we find but one more attempt in the buskin, among eighteen dramatic pieces which she afterwards wrote. In 1706, Mr. Joseph Centlivre, principal cook to queen Anne, married her; and, after passing several years happily together, she died at his house in Spring Garden, in Dec. 1723. She for many years enjoyed the intimacy and esteem of the most eminent wits of the times, viz. Sir Richard Steele, Rowe, Budgell, Farquhar, Dr. Sewell, &c. and few authors received more tokens of esteem and patronage from the great. Her plays do not abound with wit, and the language is sometimes poor; but her plots are well conducted, and her characters natural.

FREE-STONE, a whitish stone, dug up in many parts of Britain, that works like alabaster, but is more hard and durable; being of excellent use in building, &c. It is a species of the grit-stone, but finer sanded and smoother. The qualities of the several kinds of free-stones used in the different parts of Europe vary much. They all agree in this general property indeed, that they are softer while in the quarry, than when they have been some time exposed to the air: but even this general property differs greatly in degree.

FREETHINKERS. See **DEISM**, and **DEIST**.

FREEZE, FRIEZE, or FRIZE. See **FRIEZE**.

FREEZING, in philosophy, the same with congelation. See **COLD**, **CONGELATION**, **FROST**, and **ICE**. Freezing may be defined the fixing of a fluid body into a solid mass, by the action of cold. Water and some other fluids suddenly dilate and expand in the act of freezing, so as to occupy a greater space in the solid than in the liquid state: in consequence of which ice is specifically lighter than water and floats upon it. Water also loses of its weight by freezing, being found lighter after it is thawed, than before it was frozen. And it even evaporates nearly as fast while frozen, as while it is fluid. Water which has been boiled freezes more readily than that which has not been boiled; and a slight disturbance of the fluid disposes it to freeze more speedily; having sometimes been cooled several degrees below the freezing point, without congealing when kept quite still, but suddenly freezing into ice on the least motion or disturbance. Water, covered over with a surface of oil of olives, does not freeze so readily as without it; and nut-oil absolutely preserves it under a strong frost, when olive-oil would not. Rectified spirit of wine, nut-oil, and oil of turpentine, seldom freeze. The surface of water, in freezing, appears all wrinkled; the wrinkles being sometimes in parallel lines, and sometimes like rays, proceeding from a centre to the circumference. Fluids standing in a current of air grow much colder than before. Fahrenheit had long ago observed, that a pond, which stands quite calm, often acquires a degree of cold much beyond what is sufficient for freezing, and yet no congelation ensued; but if a slight breath of air happens in such a case to brush over the surface of the water, it freezes the whole in an instant. It has also been discovered, that all substances grow colder by the evaporation of the fluids which they contain, or with which they are mixed. If both these methods, therefore, be practised upon the same body at the

same time, they will increase the cold to almost any degree of intenseness we please. Although cold, in general, contracts most bodies, and heat expands them, yet there are some instances to the contrary, especially in the extreme cases or states of these qualities of bodies. Thus, though iron, in common with other bodies, expands with heat, yet, when melted, it is always found to expand in cooling again. Thus also, though water expands gradually as it is heated, and contracts as it cools, yet in the act of freezing it suddenly expands again, and that with an enormous force, capable of rending rocks, or bursting the very thick shells of metal, &c. A computation of the force of freezing water has been made by the Florentine Academicians, from the bursting of a very strong brass globe or shell, by freezing water in it; when, from the known thickness and tenacity of the metal, it was found that the expansive power of a spherule of water only one inch in diameter was sufficient to overcome a resistance of more than 27,000 pounds, or 13 tons and a half. See the experiments on bursting thick bomb-shells, by freezing water in them, by Major Edward Williams of the Royal Artillery, in the *Edin. Philos. Trans.* vol. 2. Such a prodigious power of expansion, almost double that of the most powerful steam-engines, and exerted in so small a mass, seemingly by the force of cold, was thought a very material argument in favour of those who supposed that cold, like heat, is a positive substance. Dr. Black's discovery of latent heat, however, has afforded a very easy and natural explication of this phenomenon. He has shewn, that, in the act of congelation, water is not cooled more than it was before, but rather grows warmer: that as much heat is discharged, and passes from a latent to a sensible state, as, had it been applied to water in its fluid state, would have heated it to 135°. In this process, the expansion is occasioned by a great number of minute bubbles suddenly produced. Formerly these were supposed to be cold in the abstract; and to be so subtle, that, insinuating themselves into the substances of the fluid, they augmented its bulk, at the same time that, by impeding the motion of its particles upon each other, they changed it from a fluid to a solid. But Dr. Black shews, that these are only air extricated during the congelation; and to the extrication of this air he ascribes the prodigious expansive force exerted by freezing water. The only question, therefore, is, By what means this air comes to be extricated, and to take up more room than it naturally does in the fluid? To this it may be answered, that perhaps part of the heat, which is discharged from the freezing water, combines with the air in its unelastic state, and, by restoring its elasticity, gives it that extraordinary force; as is seen also in the case of air suddenly extricated in the explosion of gun-powder. The degree of expansion of water, in the state of ice, is by some authors computed at about $\frac{1}{10}$ of its volume. Oil and quicksilver shrink and contract after freezing.

FREEZING MIXTURES, preparations for the artificial congelation of water, and other fluids. See **COLD**, and **ICE**.

FREEZING POINT denotes the point or degree of cold, by a mercurial thermometer, at which certain fluids begin to freeze, or, when frozen, at which they begin to thaw again. On Fahrenheit's thermometer, this point is at + 32° for water, and at - 40° for quicksilver, these fluids freezing at those two points respectively.

FREEZING RAIN, or RAINING ICE, a very uncommon kind of shower, which fell in the west of England, in Dec. 1672; whereof we have various accounts in the *Philos. Trans.* This rain, as soon as it touched any thing above ground, as a bough or the like, immediately settled into ice; and, by multiplying and enlarging the icicles, broke all down with its weight. The rain that fell on the snow immediately froze into ice, without sinking into the snow at all. It made an incredible destruction of trees, beyond any thing in all history. "Had it concluded with some gust of wind (says a gentleman who was on the spot,) it might have been of terrible consequence. I weighed the sprig of an ash-tree, of just three quarters of a pound, the ice on which weighed 16 pounds. Some were frightened with the noise in the air; till they discerned it was the clatter of icy boughs, dashed against each other." Dr. Beale observes, that there was no considerable frost observed on the ground during the whole time; whence he concludes, that a frost may be very intense and dangerous on the tops of some hills and plains; while in other places it keeps 2, 3, or 4 feet distant above the ground, rivers, lakes, &c. and may wander about very furiously

in some places, and remiss in others not far off. The frost was followed by glowing heats, and a wonderful forwardness of flowers and fruits.

FREIGHT, or FRAIGHT, in navigation and commerce, is the consideration of money agreed to be paid for the use or hire of a ship, or in a larger sense, the burthen of such ship. The freight is most frequently determined for the whole voyage, without respect to time: sometimes it depends on time; in the former case it is either fixed at a certain sum for the whole cargo, or so much per ton, barrel, bulk, or other weight or measure, or so much per cent. on the value of the cargo. If a certain sum is agreed on for the freight of the ship, it must all be paid, although the ship when measured should prove less, unless the burthen is warranted. If the ship is freighted for transporting cattle or slaves at so much per head, and some of them die on the passage, freight is only due for such as are delivered alive; if for lading them, it is due for all put on board. When a whole ship is freighted, if the master suffers any goods besides those of the freight to be put on board, he is liable for damages. If the voyage is completed according to the agreement, without any accident, the master has a right to demand the freight before the delivery of the goods; but if such delivery is prevented by negligence or accidents, the parties will be reciprocally responsible in the following manner. If the merchant should not load the ship within the time agreed on, the master may engage with another, and recover damages. If the merchant recalls the ship after she is laden and sailed, he must pay the whole freight; but if he unloads before the ship has actually sailed, he will in such case only be responsible for damages. If the merchant loads goods which are not lawful to export, and the ship is prevented from proceeding on that account, he must nevertheless pay the freight. If the master is not ready to proceed on the voyage at the time stipulated, the merchant may load the whole or part of the cargo on board another ship, and recover damages; but any real casualties will release the master from all damages. If an embargo is laid on the ship before she sails, the charterparty is dissolved, and the merchant pays the expence of loading and unloading; but if the embargo is only for a short limited time, the voyage shall be performed when it expires; and neither party is liable for damages. If the master sails to any other port than that agreed on, without necessity, he must sail to the port agreed on at his own expence, and is also liable for any damages in consequence of it. If a ship is taken by the enemy, and retaken or ransomed, the charterparty continues in force. If the master transfers goods from his own ship to another, without necessity, and they perish, he is responsible for the full value, and all charges; but if his own ship is in imminent danger, the goods may be put on board another ship at the risk of the owner. If a ship is freighted out and home, and a sum agreed on for the whole voyage, nothing becomes due until the return of such ship. If a certain sum is specified for the homeward voyage, it is due, although the correspondent abroad should have no goods to send home. A ship was freighted to a particular port and home, a particular freight agreed upon for the homeward voyage, with an option reserved for the correspondent to decline it, unless the ship arrived before a certain day. The master did not go to the port agreed on, and therefore became liable to damages; the obligation being absolute on his part, and conditional only on the part of the freighter. If the goods are damaged without fault of the ship or master, the owner is not obliged to receive them and pay the freight, but he must either receive or abandon the whole; he cannot receive those that are not damaged, and reject the others. If the goods are damaged through the insufficiency of the ship, the master is liable for the same; but if it is owing to stress of weather he is not accountable. If part of the goods is thrown overboard or taken by the enemy, the part delivered pays freight. The master is accountable for all the goods received on board by himself and mariners, unless they perish by the act of God, or the king's enemies. The master is not liable for leakage of liquors, nor accountable for contents of packages, unless packed in his presence.

FREIND, JOHN, a learned English physician and author, born at Croton, in Northamptonshire, in 1675. In 1696, he published, in conjunction with Mr. P. Foulkes, an edition of two Greek orations, viz. of *Æschines* against *Ctesiphon*, and *Demosthenes* de *Corona*, with a new Latin version. In 1699, he wrote a letter to Dr. Sloane concerning an *Hydrocephalus*, published in the *Philosophical Transactions*, and another letter in Latin to

the same gentleman, *De Spasmi rarioris*, *Historia*, printed in the same *Transactions*. In 1703, his *Emmenologia* appeared; which gained him great reputation. In 1704, he was chosen professor of chemistry in the university of Oxford. In 1705, he attended the earl of Peterborough to Spain, as physician to the army there; and upon his return in 1707, published an account of the earl's expedition. In 1709, he published his *Chemical Lectures*. In 1712, he attended the duke of Ormond in Flanders, as his physician. In 1716, he was admitted a fellow of the college of physicians in London. This year he published the first and third books of *Hippocrates De Morbis popularibus*, with a Commentary on Fevers, written by himself. He sat M. P. for Launceston in Cornwall in 1722, where he distinguished himself by his opposition to the ministry. In March 1722, he was committed to the tower on a charge of high treason: and while he was under confinement, he wrote a Latin epistle to Dr. Mead, *De quibusdam Variolarum Generibus*; and began his *History of Physic*, the first part of which was published in 1725, and the second in 1726. Upon the accession of George II, he was appointed physician to the queen, who shewed the utmost esteem for him. He died at London in 1728. His works were published together in Latin at London by Dr. Wigan, in folio, in 1733, and dedicated to the queen.

FREJULS, or FREJUS, a town of France, in the department of Var, anciently called *Forum Julium*, or *Julii*. It is seated near the *Argens*, 40 miles N. E. of *Toulon*.

FRENAYE, two towns of France, in the department of Sarthe; 1. six miles E. of *Alençon*: 2. nine miles S. S. W. of *Alençon*.

FRENCH BEAN, in botany. See *PHASEOLUS*.

FRENCH BROAD, a navigable river of Tennessee, which joins the *Holstein* 11 miles above *Knoxville*.

FRENCH LANGUAGE, the language now spoken in France, which, like the English, is not an original language, but a medley of several. Those that prevail most, and are the basis of it, are, 1. The Celtic; whether that were a particular language itself, or whether it were only a dialect of the Gothic, as spoke in the West and North: 2. The Latin, which the Romans carried with them into Gaul, when they conquered it: And, 3. The Teutonic, or that dialect of the Teutonic spoken by the Franks, when they passed the Rhine, and established themselves in Gaul. Of these three languages, in the space of about 1300 years, was the modern French gradually formed. Its progress was very slow. Both the Italian and Spanish were regular languages long before the French. One character of the French language is, that it is natural and easy. The words are ranged in it much in the same order as the ideas in our minds, in which it differs exceedingly from the Greek and Latin, where the inversion of the natural order of words is reputed a beauty. The Hebrew surpasses even the French in this point, but comes short of it in copiousness and variety. But, as to the analogy of grammar, and the simplicity where-with the moods of verbs are formed, the English has the advantage not only over the French, but over all the known languages in the world; though the peculiar expressions and idioms of the English are sometimes so quaint and extraordinary, that it loses a good deal of the advantage which its grammatical simplicity gives it over the rest. The French has few compound words, wherein it differs widely from the Greek, High Dutch, and English. This the French authors acknowledge to be a great disadvantage; the Greek and Dutch deriving a great part of their force and energy from the composition of words, and frequently expressing that in one sounding word, which the French cannot express but by a periphrasis. The diminutives in the French are as few as the compounds, the greatest part of those in use having lost their diminutive signification. The French is chiefly admired for its justness, purity, accuracy, and flexibility. It is the most universal and extensive language in Europe. The policy of states and courts has rendered it necessary for the ministers of princes, &c. and the discoveries and improvements made by the French in arts and sciences have had the same effect among the learned. In Germany, and elsewhere, the princesses and persons of distinction value themselves on understanding French; and in several courts of Europe, French is almost as much used as the language of the country.

FRESCATI, or FRASCATI, a small town of Italy, on the brow of a hill, 10 miles S. E. of *Rome*.

FRESCO, a method of painting in relieve on walls, so as to endure

endure the weather. It is performed with water-colours on fresh plaster, or on a wall laid with mortar not yet dry. This sort of painting has a great advantage by its incorporating with the mortar, and, drying along with it, becomes very durable. The Italians, from whom we borrow the term, call it fresco; because it is frequently used for walls, alcoves, and other buildings in the open air. Vitruvius, (lib. vii. cap. 4.) calls it *udo tectorio*. Painting in fresco is very ancient, having been practised in the earliest ages of Greece and Rome. See PAINTING.

FRESH DISSEISIN, in law, such a disseisin, as a man may defeat of himself, as where it is within 15 days.

FRESH FORCE, a force newly done; as where a man is deforced of lands after the death of his ancestor, the person having right may within 40 days bring his bill of fresh force and recover the lands.

FRESH SHOT, in sea-language, the falling down of any large river into the sea, whereby the sea has fresh water a great way from its mouth.

FRESHES, in sea-language, denote the impetuosity of an ebb tide, increased by heavy rains, and flowing out into the sea, often discolouring it to a considerable distance, and forming a line that separates the two colours, and which may be distinctly perceived for a great length along the coast.

FRESHES, a local term signifying annual inundations, from the rivers being swollen by the melted snows and other fresh waters from the uplands, as is the Nile, &c. from periodical or tropical rains. As a sailor's term, it is opposed to marine or salt water floodings, tides, &c. The word is of common use in America, where the inundations so called are of great service.

FRESNE, CHARLES DE, SIEUR DU CANGE, one of the most learned writers of his time, was born at Amiens in 1610, and studied at the Jesuits' college in that city. Afterwards he studied the law at Orleans, and gained great reputation by his works; among which are, 1. The history of Constantinople under the French emperors. 2. John Cinnamus's History of the affairs of John and Manuel Comnenus, in Greek and Latin, with historical and philological notes. 3. Glossarium ad Scriptores mediæ & infimæ Latinitatis: 6 vols. folio. 4. A Greek Glossary, consisting of curious passages from rare M. S. S. 2 vols. folio. He died in 1688, aged 78. Lewis XIV settled pensions on his four children.

FRET, or FRETTE, in architecture, a kind of knot or ornament, consisting of two lists or small fillets variously interlaced or interwoven, and running at parallel distances equal to their breadth.

FRET-WORK, work adorned with frets. It is sometimes used to fill up and enrich flat empty spaces; but it is mostly practised in roofs, which are fretted over with plaster-work.

FRET, in heraldry, a bearing composed of six bars, crossed and variously interlaced. Some call it the true lover's knot. See HERALDRY.

FRET, in music, a kind of stop on some instruments, particularly bass-voils and lutes. Frets consist of strings tied round the neck of the instrument, at certain distances, within which such and such notes are to be found.

FRETOY, a town of France, in the department of the Oise, 5 miles N. W. of Noyon.

FRETTS, in mineralogy, a term used by miners to express the worn side of the banks of the rivers in mine-countries, where they search for the shoad stones or grewts washed down from the hills, in order from thence to trace out the running of the shoad up to the mine.

FREUDENBERG, the name of three towns of Germany: viz. 1. in the circle of Bavaria, four miles E. of Amberg; 2. in that of Franconia, 8 miles N. of Wertheim; 3. in Westphalia, 5 miles W. N. W. of Siegen.

FREUDENSTADT, a fortified town of Suabia, with a citadel, in the kingdom of Wirtemberg: 24 miles S. E. of Strasburg.

FREVENT, a town of France, in the department of the Straits or Calais; 7½ miles S. of St. Pol, and 6 W. of Arras.

FREYA, FRIA, or FRIGGA, the Venus of the Saxons. See FREA. The following German towns appear to have been named from her:

FREYBERG or FRIDBERG, a town of Upper Saxony in the matgraviate of Meissen, 19 miles W. S. W. of Dresden.

FREYBORG or FRIBOR, a town of Moravia, 28 miles E. N. E. of Prerau, and 36 E. of Olmutz.

FREYBURG, a town of Silesia, in Schweidnitz, near the Pohnitz, 7 miles W. of Schweidnitz.

FREYBURG, or FRIBURG, a town of Upper Saxony, 16 miles S. of Halle, and 4 N. N. W. of Naumburg.

FREYE-ÆMTER, a territory of the Helvetic republic, surrounded by the cantons of Zurich, Bern, Lucerne, and Zug; anciently called Rori and Waggenthal.

FREYENSTADT, a town of Bavaria, 20 miles S. E. of Nuremberg, and 31 N. W. of Ratisbon.

FREYENTHURN, a town of Carniola, on the Kulp, 7 miles S. of Rudolfswoth.

FREYENWALD, a town of Brandenburg, on the Oder, 24 miles N. W. of Custrin, and 32 N. E. of Berlin.

FREYSINGEN, or FRIESINGEN, an ecclesiastical principality in Bavaria, between Munich and Landshut. It comprehends the counties of Ismaning and Werdenfels, and the lordship of Burgkrain.

FREYSINGEN, the capital of the above bishopric.

FREYSTADT; two towns of Silesia: 1. in the principality of Glogau, 14 miles N. E. of Sagan; 2. in that of Teschen, 7 miles, N. N. W. of Teschen.

FRIAR, or FRIER, [*Lat. frater, Ital. fra, and French frere, i. e. brother*:] a term common to monks of all orders; founded on this, that there is a kind of brotherhood presumed between the religious persons of the same monastery. Friars are generally distinguished into these four principal branches, viz. 1. Franciscans, Minors, or grey friars: 2. Augustines: 3. Dominicans, or black friars: 4. Carmelites, or white friars. From these four the rest of the orders descend. See these articles.

FRIAR, in a more peculiar sense, is restrained to such monks as are not priests; for those in orders are usually dignified with the appellation of father.

FRIARS OBSERVANT, [*fratres observantes*,] were a branch of the Franciscans; thus called, because not combined together in any cloister, convent, or corporation, as the conventuals are, but only agreed among themselves to observe the rules of their order.

FRIBURG, or FREYBURG, a large town of Germany, in Suabia capital of Austrian Brigaw, 10 miles E. of Brisach, and 34 S. S. E. of Strasburg. Lon. 7. 57. E. Lat. 48. 4. N.

FRIBURG, a town of Germany, in Upper Bavaria, 15 miles S. S. E. of Brannau, and 18 of Burkhausen.

FRIBURG, or FREYBURG, a town of the Helvetic republic, capital of the canton seated on the Sane, 15 miles S. W. of Bern, and 75 of Zurich. Lon. 6. 53. E. Lat. 46. 48. N.

FRIBURG, one of the cantons of Switzerland. It is surrounded on all sides by the canton of Bern. The land is fertile in corn, fruits, and pastures: and the canton can send 18,000 men into the field.

FRICENTI, or FRICENTY, an episcopal town of Naples, in Principato Ultra, near the Tripalto: 12 miles N. W. of Conza.

FRICTION, [*friction, Fr. frictio, from frico, Latin*,] the rubbing of bodies together called also attrition. The phenomena arising upon the friction of divers bodies, under different circumstances, are very numerous and considerable. Mr. Hawksbee gives a number of experiments of this kind; particularly of the attrition or friction of glass, under various circumstances, the result of which was, that it yielded light and became electrical. All bodies by friction are brought to conceive heat; many of them to emit light; particularly a cat's back, sugar, beaten sulphur, mercury, sea-water, gold, copper, &c. but, above all, diamonds, which when briskly rubbed against glass, gold, or the like, yield a light equal to that of a live coal when blown by the bellows. See ELECTRICITY.

FRICTION, in mechanics, the rubbing of the parts of engines and machines against each other, by which means a great part of their effect is destroyed. It arises from the roughness or asperity of the surface of the body moved on, and that of the body moving: for such surfaces consisting alternately of eminences and cavities; either the eminences of the one must be raised over those of the other, or they must be both broke and worn off; but neither can happen without motion; nor can motion be produced without a force impressed. Hence, the force applied to move the body is either wholly or partly spent on this effect; and consequently there arises a resistance or friction which will be greater, ceteris ar-

bus;

bus, as the eminences are the greater and the substance the harder: and as the body, by continual friction, becomes more and more polished, the friction diminishes. Messrs. Amontons, De La Hire, Cams, Desaguliers, Muschenbroek, Ferguson, Euler, and other mechanicians, have made a number of ingenious experiments to settle a principle for the exact calculation of the quantity of friction. But the most successful set of experiments, made on this subject, are those of the Rev. Samuel Vince A. M. of Cambridge, published in the 75th Vol. of the Philosophical Transactions, p. 165. Mr. Emerson, in his Principles of Mechanics has also made several important remarks on the friction of wood and metals. See MECHANICS.

FRICTION, in medicine, is the act of rubbing a diseased part with oils, unguents, and other matters, in order to ease, relieve, and cure it. Friction is also performed with a flesh-brush, a linen-cloth, or with flannel; which last is the most eligible. It is a kind of exercise that remarkably contributes to the health of sedentary persons; for it excites and kindles the natural warmth; diverts fluxions; promotes perspiration; opens the pores: and tends to dissipate stagnant humours. This operation is particularly beneficial to the nervous, debilitated, and studious; being an useful substitute for other exercise. Hence we recommend to such individuals to spend half an hour every morning and evening in rubbing their whole body, especially their limbs, with a clean piece of flannel. It ought, however, to be observed, that this practice will be of the greatest service when the stomach and bowels are empty. Lastly, we venture to affirm, that the most important purposes to which friction may be rendered subservient in the animal economy, have hitherto been almost entirely neglected: we are, however, convinced from experience, that medicated frictions, or the introduction of the most active medicines into the human system, by rubbing them in properly on the surface, might be attended with the most happy effects, especially in all chronic diseases. Common sense appears to have long since pointed out this excellent method of administering medicines, even to the Indian savages, though it is little practised in enlightened Europe, where the stomach is doomed to be the field of battle, for deciding commotions and irregularities in our complicated frame. But who is hardy enough to maintain, that the digestive organ was by Nature destined to be the exclusive vehicle of drugs, and to serve as their common laboratory.

FRIDBERG, a town of Germany, in Bavaria, 4 miles S. E. of Augsburg, and 28 W. N. W. of Munich.

FRIDBERG, an imperial town of Germany, in Weteravia, 12 miles N. E. of Frankfurt, and 28 E. N. E. of Mentz.

FRIDBERG, a town of Germany in Stiria, 32 miles E. of Pruck, and 42 S. of Vienna.

FRIDBURG, a town of Germany, in Upper Saxony, 30 miles W. of Leipsick.

FRIDECK, a town of Silesia, 10 miles W. S. W. of Teschen, and 10 S. of Odelberg.

FRIDECK, a town of Prussia, 12 miles E. of Culm.

FRIDING, a town of Germany, in Suabia, 30 miles N. E. of Constance.

FRIDLAND, a town of Bohemia, 55 miles E. of Dresden.

FRIDSTOL, one of the ancient immunities granted to churches. The word signifies a seat, chair, or place of peace and security, where criminals might find safety and protection. Of these there were many in England; but the most famous were those at Beverly; and in St. Peter's church at York, granted by charter of king Henry I.

FRIEDBERG, or **FRIEDENBURG**, a town of Silesia, in the duchy of Jauer, on the Queiss; 11 miles W. of Lowenberg.

FRIEDBERG HOHEN, a town of Silesia, in the duchy of Schweidnitz; 5 miles S. W. of Striegau.

FRIEDEBURG, a town of Westphalia, in E. Friesland, 22 miles E. N. E. of Embden.

FRIEDERICKSTED, a town on the W. coast of Santa Cruz. Lon. 93. 25. W. Lat. 17. 48. N.

FRIEDLINGEN, or **FRIDLINGEN**, a town and fort of Suabia, 3 miles E. of the Rhine, and 4 N. of Basle.

FRIENDLY ISLANDS, a cluster of 60 islands, in the Pacific Ocean, so named by Capt. Cook in 1773, on account of the friendship which appeared to subsist among the inhabitants, and from their courteous behaviour to strangers. The chief of these

islands are Annamooka, Tangataboo, Lefooga, and Taöoa, or Middleburg. The natives of these islands seldom exceed the common stature, but are very strong and well made. These islands lie between 170° and 180° Lon. W. and between 20° and 23° Lat. S.

FRIENDS, or **QUAKERS**, a numerous and respectable religious society, which took its rise about the middle of the 17th century; and spread very quickly into the British colonies in North America, as well as into various countries in Europe. The members called themselves at first Seekers, from their seeking the truth; but after their society was formed, assumed the name of Friends. The name of Quakers was given them in derision. George Fox, a shoemaker, (see Fox,) is generally allowed to have been the founder of this Society. They were soon after joined by a number of learned, ingenious, and pious men. The chief of these were George Keith, the justly celebrated William Penn, (see PENN,) and Barclay of Ury. They believe in one eternal God, the Creator and Preserver of the universe; and in Jesus Christ his Son, the Messiah, and Mediator of the new Covenant, (Heb. xii. 24.) To Christ alone they give the title of the Word of God, (John i. 1.) They hold, that the scriptures are able to make wise unto salvation, through faith in Christ Jesus, (2 Tim. iii. 15.) They reverence the precepts of our Lord, and believe that in the life to come every man will be rewarded according to his works, (Matt. xvi. 27.) And that, to enable mankind to practise these sacred precepts, many of which are contradictory to the unregenerate will of man, (John. i. 9,) every man coming into the world is endued with a measure of the light, grace, or good Spirit, of Christ; by which, as it is attended to, he is enabled to distinguish good from evil, and to correct the disorderly passions and corrupt propensities, of his nature, which mere reason is altogether insufficient to overcome. They consider as obstructions to pure worship, all forms which divert the attention of the mind from the secret influence of this unction from the Holy One, (1 John ii. 20, 27.) They meet often together, (Heb. x. 25,) in testimony of their dependence on the heavenly Father, and for a renewal of their spiritual strength: nevertheless, in worship they do not depend for acceptance with him, on a formal repetition of the words and experiences of others; but they believe it to be their duty to cease from the activity of the imagination, and to wait in silence for a true sight of their condition: believing even a single sigh, (Rom. viii. 26,) arising from such a sense of their infirmities, to be more acceptable to God, than any performances, which originate in the will of man. They believe the renewed assistance of the light and power of Christ to be indispensably necessary for all true ministry; and that this holy influence is not at our command, or to be procured by study, but is the free gift of God to his chosen and devoted servants. Hence they object to preaching for hire, (Matt. x. 8,) and consequently to the payment of tithes. As male and female are one in Christ, they allow such of the female sex as have a right qualification to exercise their gifts in the ministry: and this liberty they esteem to be a peculiar mark of the gospel dispensation, as foretold by the prophet Joel, (Joel ii. 28, 26,) and noticed by the apostle Peter, Acts ii. 16, 17.) They hold that baptism is one in nature and operation; that nothing short of it can make living members of Christ's mystical body; and that the baptism with water, administered by John, belonged, as the latter confesses, to an inferior and decreasing dispensation, (John iii. 30.) They therefore practise it not. They believe that communion between Christ and his church is not maintained by the Lord's Supper nor any other external performance, but only by a real participation of his divine nature, (2 Pet. i. 4,) through faith; that this is the supper alluded to in the Revelation, (See Rev. iii. 20,) and that where the substance is attained, it is unnecessary to attend to the shadow. With respect to oaths, they abide literally by Christ's positive injunction, "Swear not at all." Wars and fightings they consider in their origin and effects, utterly repugnant to the Gospel. They inculcate submission to the laws in all cases wherein conscience is not violated. But as Christ's kingdom is not of this world, they think the magistrate ought not to interfere in matters of religion; but to maintain the external peace and good order of the community. They are careful in requiring their members not to be concerned in illicit trade, nor in any manner to defraud the revenue. The society, from its first appearance, disused those names of the months and days which,

which, having been given in honour of the heroes or false gods of the heathens, originated in their flattery or superstition; and the custom of speaking to a single person in the plural number, as having arisen also from motives of adulation. Compliments, superfluity of apparel and furniture, outward shows of rejoicing and mourning, and observation of days and times, they esteem incompatible with the simplicity and sincerity of the Christian life; and public diversions, gaming, and other vain amusements of the world, they condemn. They think that a true and living faith is not produced in the mind of man by his own effort; but is the free gift of God, (Eph. ii. 8,) in Christ Jesus, nourished and increased by the progressive operation of his Spirit in our hearts, and our proportionate obedience, (John vii. 17.) They require no formal subscription to any articles, either as the condition of membership, or to qualify for the service of the church, but prefer judging of men by their fruits. In the practice of discipline, they think it indispensable that the order recommended by Christ himself be invariably observed: (See Matth. xviii. 15, to 17.) For the purposes of discipline, meetings were appointed, at an early period of the society, which, from the times of their being held, were called quarterly meetings. It was afterwards found expedient to divide the districts of those meetings, and to meet oftener; whence arose monthly meetings, subordinate to those held quarterly. At length, in 1669, a yearly meeting was established, to superintend, assist, and provide, rules for the whole; previous to which general meetings had been occasionally held. A monthly meeting is usually composed of several particular congregations, situated within a convenient distance of each other. Its business is to provide for the subsistence of their poor, and for the education of their offspring; to judge of the sincerity and fitness of persons desiring to be admitted into membership; to excite due attention to the discharge of religious and moral duty; and to deal with disorderly members. Monthly meetings also grant to such of their members as remove into other monthly meetings, certificates of their membership and conduct. Each monthly meeting is required to appoint overseers, to take care that the rules of discipline be put in practice. In disputes between individuals, members should not sue each other at law. They are enjoined to apply to arbitration, agreeable to rules laid down. If any refuse he is disowned. To monthly meetings also belongs the allowing of marriages. Those who intend to marry, appear together and propose their intention to the monthly meeting; and if not attended by their parents or guardians produce a written certificate of their consent, signed by witnesses. The meeting then appoints a committee to inquire whether they are clear of other engagements respecting marriage; and if at a subsequent meeting, to which the parties also come and declare the continuance of their intention, no objections are reported, they have the meeting's consent to solemnize their intended marriage. This is done in a public meeting for worship; towards the close whereof the parties stand up, and solemnly take each other for husband and wife. A certificate of the proceedings is then publicly read, and signed by the parties, and afterwards by the relations and others as witnesses. Of such certificates the monthly meeting keeps a record; as also of the births and burials of its members. A certificate of the date, of the name of the infant, and of its parents, signed by those present at the birth, is the subject of one of these last-mentioned records; and an order for the interment, countersigned by the grave-maker, of the other. The naming of children is without ceremony. Burials are also conducted in a simple manner. The body, followed by the relations and friends, is sometimes, previously to interment, carried to a meeting; and at the grave a pause is generally made; on both which occasions it frequently falls out that one or more friends present have somewhat to express for the edification of those who attend: but no religious rite is considered as an essential part of burial. Several monthly meetings compose a quarterly meeting. The yearly meeting has the general superintendence of the society in the country in which it is established. Appeals from the judgement of quarterly meetings are here finally determined; and correspondence is maintained with other yearly meetings. The women have quarterly and yearly meetings, of their own sex, held at the same time and in the same place with those of the men; but separately, and without the power of making rules. Elders are selected of either sex, who, by their experience in the work of religion, are qualified for that service. These, and ministers approved by their monthly meetings, have

meetings peculiar to themselves, called meetings of ministers and elders; in which they have an opportunity of exciting each other to a discharge of their several duties. The yearly meeting held in London, in 1675, appointed a meeting to be held in that city for the purpose of advising and assisting in cases of suffering for conscience sake, which hath continued to this day. It is composed of friends under the name of correspondents, chosen by the several quarterly meetings, and who reside in or near the city. The same meetings also appoint members of their own in the country as correspondents, who are to join their brethren in London on an emergency. There is not in any of the meetings a president, as they believe that Divine Wisdom alone ought to preside. The office of clerk, with a few exceptions, is undertaken voluntarily by some member; as is also the keeping of the records. Where these are very voluminous, and require a house for their deposit, a clerk is hired to have the care of them; but except a few clerks of this kind, and persons who have the care of meeting-houses, none receive any stipend or gratuity for their services in the society.

FRIESACH, a town of Carinthia, in the archbishopric of Salzburg, 56 miles S. E. of Salzburg.

FRIESINGEN, FREISINGEN, FREYSINGEN, or FRI-SINGEN, a town of Bavaria, 17 miles N. N. E. of Munich.

FRIESLAND, or NORTH FRIESLAND, one of the late United Provinces, now included in the French empire. It was so named from the Frisians, and was bounded on the E. by the Lauvers, which separates it from Groningen, on the S. by Overysse, on the W. by the Zuyder Zee, and on the N. by the German ocean. It is 30 miles from N. to S. and 28 from E. to W. The land is very fertile in corn and pasture; the horses are large and the cows and sheep prolific.

FRIESLAND, EAST, a late province of Germany, in the ci-devant circle of Westphalia, near the German ocean. The principal towns are Emden, Norden, Leer, Essens, Whitemunde, and Aurick.

FRIESLAND, WEST, a name given to that part of Batavia, lately called North Holland; now included in the department of the Texel, and united to the French empire.

FRIEZE, (drap de frise, Fr.) a coarse warm cloth, made perhaps first in Friesland.

FRIEZE, in commerce, a coarse kind of woollen stuff, or cloth, for winter-wear; so called, as being friezed or naped on one side.

FRIEZE, or FRIZE, in architecture, a large flat member which separates the architrave from the cornice; of which there are as many kinds as there are orders of columns. See **ARCHITECTURE**.

FRIGATE, among seamen, a ship of war, light built, and that is a good sailer.

FRIGATES, are usually of two decks; light-built, designed for swift sailing. When smaller, with but one deck, they are called light frigates. Those mounting from 20 to 44 guns are esteemed excellent cruisers. The name was formerly known only in the Mediterranean, and applied to a long kind of vessel navigated in that sea with sails and oars. The English were the first who appeared on the ocean with these ships, equipped for war as well as for commerce.

FRIGATOON, a Venetian vessel, commonly used in the Adriatic, built with a square stern, and without any fore-mast, having only a main-mast, mizen-mast, and bow-sprit.

FRIGHT, or TERROR, sudden fear; it is frequently productive of very remarkable effects upon the human system. Of this many instances occur in medical writings. In general, the effects of terror are a contraction of the small vessels and a repulsion of the blood in the large and internal ones: hence proceed general oppression, trembling, and irregularity in the motions of the heart; while the lungs are also overcharged with blood. Frights often occasion incurable diseases, as epilepsy, stupor, madness, &c. In this way they have killed many, by the agitation into which they have thrown the spirits. We have also accounts of persons absolutely killed by terror, when in perfect health at the time of receiving the shock. Persons ordered to be led to execution, but with private orders to be reprieved on the scaffold, have expired at the block without a wound. Out of many instances of the fatal effects of fear, the following is selected as one of the most singular: "George Grochantzy, a Polander, who had enlisted as a soldier in the service of the king of Prussia, deserted during the last war. A small party was sent in pursuit of him, and, when he least expected it, surprised him singing and dancing among a com-

pany of peasants, in an inn. This event so sudden and so dreadful in its consequences, struck him in such a manner, that, giving a great cry, he became altogether stupid and insensible, and was seized without the least resistance. They carried him away to Gloau, where he was brought before the council of war, and received sentence as a deserter. He suffered himself to be led and disposed of, at the will of those about him, without uttering a word, or giving the least sign that he knew what had happened, or would happen to him. He remained immoveable as a statue wherever he was placed, and was wholly passive with respect to all that was done to him or about him. During all the time that he was in custody, he neither eat, nor drank, nor slept, nor had any evacuation. Some of his comrades were sent to see him; after that he was visited by some officers of his corps, and by some priests; but he still continued in the same state, without discovering the least signs of sensibility. Promises, intreaties, and threatenings, were equally ineffectual. The physicians were of opinion, that he was in a state of hopeless idiocy. It was at first suspected that those appearances were feigned; but these suspicions gave way, when it was known that he took no sustenance; and that the involuntary functions of nature were in a great measure suspended. After some time they knocked off his fetters, and left him at liberty to go whither he would. He received his liberty with the same insensibility that he had shewn upon other occasions; he remained fixed and immoveable; his eyes turned wildly here and there without taking cognizance of any object, and the muscles of his face were fallen and fixed like those of a dead body. Being left to himself, he passed twenty days in this condition, without eating, drinking, or any evacuation, and died on the twentieth day. He had been sometimes heard to fetch deep sighs; and once he rushed with great violence on a soldier, who had a mug of liquor in his hand, forced the mug from him, and having drank the liquor with great eagerness, let the mug drop to the ground." When a person is affected with terror, the principal endeavour should be to restore the circulation to its due order; to promote perspiration, and to allay the agitation of the patient. For these purposes he may drink a little warm liquor, as camomile tea, &c. the feet and legs may be put into warm water, the legs rubbed, and the camomile tea repeated every six or eight minutes; and when the skin is warm, and there is a tendency to perspiration, sleep may be promoted by a gentle opiate. Yet frights have been known to cure, as well as to cause, diseases. Mr. Boyle mentions agues, gout, and sciatica, thus cured. Among the ludicrous effects of fear, the following instance, quoted from a French author by Mr. Andrews in his volume of Anecdotes, shews upon what slight occasions this passion may be sometimes excited in a very high degree, and even in persons the most unlikely to entertain fear. "Charles Gustavus (the successor of Christina, queen of Sweden) was besieging Prague, when a boor of most extraordinary visage desired admittance to his tent; and being allowed entrance, offered, by way of amusing the king, to devour a whole hog of 100 weight in his presence. The old general, Konigsmarc, who stood by the king's side, and who, soldier as he was, had not got rid of the prejudices of his childhood, hinted to his royal master that the peasant ought to be burnt as a sorcerer. 'Sir, said the fellow, irritated at the remark, if your majesty will but make that old gentleman take off his sword and his spurs, I will eat him immediately before I begin the hog.' Konigsmarc (who had, at the head of a body of Swedes, performed wonders against the Austrians, and who was looked upon as one of the bravest men of the age,) could not stand this proposal, especially as it was accompanied by a most hideous and preternatural expansion of the frightful peasant's jaws. Without uttering a word, the veteran suddenly turned round, ran out of the court, and thought not himself safe until he had arrived at his quarters; where he remained above twenty-four hours locked up securely, before he had got rid of the panic which had so severely affected him." The ingenious Dr. Beattie observes, in his Elements of Moral Science, that "fear should not rise higher than to make us attentive and cautious; when it gains an ascendancy in the mind, it becomes an insupportable tyranny, and renders life a burden. The object of fear is evil; and to be exempt from fear, or at least not enslaved to it, gives dignity to our nature, and invigorates all our faculties. Yet there are evils which we ought to fear. Those that arise from ourselves, or which it is in our power to prevent, it would be madness

to despise, and audacity not to guard against. External evils, which we cannot prevent, or could not avoid without a breach of duty, it is manly and honourable to bear with fortitude. Insensibility to danger is not fortitude, no more than the incapacity of feeling pain can be called patience; and to expose ourselves unnecessarily to evil is worse than folly, and very blameable presumption. It is commonly called fool-hardiness; that is, such a degree of hardness or boldness as none but fools are capable of.

FRIGID ZONE. See ZONE.

FRILAZIN, a class or rank of people among the Anglo-Saxons, consisting of those who had been slaves, but had obtained their liberty, either by purchase or otherwise.

FRINGILLA, the FINCH, in ornithology, a genus of the class aves, order passerres. Bill conical, straight, sharp-pointed. There are a hundred and eight species comprehended under this genus, distinguished principally by varieties in their colour.

F. CÆLEBS, the CHAFFINCH, has black limbs, and the wings white on both sides; the three first feathers of the tail are without spots, but the two chief ones are obliquely spotted. It has its name from its delighting in chaff. This species entertains us agreeably with its song very early in the year, but towards the end of summer assumes a chirping note: both sexes continue with us the whole year. In Sweden the females quit that country in September, migrate in flocks into Holland, leaving their mates behind, and return in spring.

F. CANARIA, the CANARY-BIRD, hath a whitish body and bill, with the prime feathers of the wings and tail greenish. It was originally peculiar to those isles to which it owes its name. See CANARY. It is supposed to have been first brought to Europe in the fourteenth century. At a still later period Canary-birds were more generally introduced into Germany, where the greatest attention is paid to the breeding and rearing of these beautiful creatures, which are much celebrated for their song, and docility in imitating musical notes. Hence they are become a source of considerable emolument to the Tyrolese, who export vast numbers to various parts of Europe, and also to England. If treated with proper care they will breed, and become as vigorous and healthy in this country as in their native islands. These delicate birds are subject to a variety of diseases; to prevent which, the greatest care should be taken to provide them with pure water and simple food. During the time of moulting, which often proves fatal to many of them, a little white wine dropped on a piece of biscuit, or sugar, will be of considerable service. The Canary-bird will prove fertile with the siskin and goldfinch; but in this case the produce for the most part proves sterile: the pairs succeed best when the hen is the Canary, and the cock of the opposite species. She will also prove prolific with the linnet, yellow-hammer, chaffinch, and even the house-sparrow; but the male Canary-bird will not assimilate with the female of any of these species; the hen must be always of the Canary species, and the young generally prove males. Canaries are said by some to live fifteen years, by others eighteen.

F. UARDUELIS, the GOLDFINCH, with the quill-feathers red forwards, and the outermost without any spots; the two outermost are white in the middle, as the rest are at the point. The young bird before it moults is grey on the head; and hence it is termed by the bird-catchers a grey-pate. Their note is very sweet, and they are much esteemed on that account, as well as for their great docility. Towards winter they assemble in flocks, and feed on various seeds, particularly those of the thistle. They are fond of orchards, and often build in apple or pear-trees. Their nests are very elegantly formed of fine moss, liverwort, and bents, on the outside; lined first with wool and hair, and then with the goslin or cotton of the swallow. Goldfinches often attain the age of twenty years. They abound throughout Europe; and are also met with in Asia and Africa, but less commonly.

F. DOMESTICA, the SPARROW, has the prime feathers of the wings and tail brown, the body variegated with grey and black, and a single white streak on the wings. These birds are proverbially salacious, and have three broods in the year. They are every where common about our houses, where they build in every place they can find admittance; under the roof, corner of the brick-work, or in holes of the wall. They make a slovenly nest; generally a little hay ill put together, but lined well with feathers; where they lay five or six eggs of a reddish-white colour spotted

with

with brown. They sometimes build in trees, in which case they take more pains with the nest; and often expel the martins from theirs, to save the trouble from constructing one of their own. Sparrows, from frequenting only habitations and parts adjacent, may be said to be chiefly fed from human industry; for in spite of every precaution they will partake with the pigeons, poultry, &c. in the food thrown out to them, grain of all kinds being most agreeable to their taste, though they will eat refuse from the kitchen of most kinds. They are familiar but crafty, and do not so easily come into a snare as many others. In autumn they often collect into flocks, and roost in numbers on the neighbouring trees, when they may be shot by dozens, or caught in great numbers at night by a bat fowling net. The sparrow has no song, only a chirp or two frequently repeated. This species is found every where throughout Europe; and is also met with in Egypt, Senegal, Syria, and other parts of Africa and Asia.

F. LINOTA, the **LINNET**, has the bottom of the breast of a fine blood-red, which heightens as the spring advances. These birds are much esteemed for their song. They feed on seeds of different kinds, which they peel before they eat; the seed of the linum, or flax, is their favourite food; from whence the name. They breed among furze and white thorn: the outside of their nests is made with moss and bents, and lined with wool and hair. They lay five whitish eggs, spotted like those of the goldfinch.

F. SPINUS, the **SISKIN**, has the prime feathers of the wings yellow in the middle, and the four first chief tail feathers without spots; but they are yellow at the base, and black at the points. It visits these islands at very uncertain times, like the gross-beak, &c. It is to be met with in the bird-shops in London; and being rather scarce, sells at a higher price than the merit of its song deserves; it is known there by the name of the aberdavine. It is very tame and docile, and is often kept and paired with the Canary-bird, with which it breeds freely. Dr. Kramer informs us, that this bird conceals its nest with great art; and though there are infinite numbers of young birds in the woods on the banks of the Danube, which seem just to have taken flight, yet no one could discover it. See Plate LVIII.

FRISEI, **FRISII**, **FRISIONES**, or **FRISONES**, an ancient people of Germany, so called either from their ardent love of freedom, or from the fresh and unbroken lands they occupied.

FRISORT, a town of Germany, in the bishopric of Munster, 14 miles S. W. of Oldenburg.

FRIT, in the glass-manufacture, is the matter or ingredients whereof glass is to be made, when they have been calcined or baked in a furnace. A salt drawn from the ashes of the plant kali, or from fern or other plants mixed with sand or flint, and baked together, makes an opaque mass, called by glassmen frit; probably from the Italian *frittare*, to fry; or because the frit, when melted, runs into lumps, like fritters, called by the Italians *fritelli*. Frit, by the ancients, was called ammonitrum, of *αμμος*, sand, and *νιτρον*, nitre; under which name it is thus described by Pliny: fine sand from the Volturian sea, mixed with three times the quantity of nitre, and melted, makes a mass called ammonitrum, which being rebaked makes pure glass. There are three kinds of frits: 1. The crystal frit, or that for crystal metal, made with salt of pulverine and sand. 2. The ordinary frit, made with bare ashes of pulverine or barilla, without extracting the salt from them. This makes the ordinary white or crystal metal. 3. The frit for green glasses, made of common ashes, without any preparation. This last requires ten or twelve hours baking. The materials in each are to be finely powdered, washed, and seared; then equally mixed, and frequently stirred together in the melting-pot.

FRITH, usually signifies the opening of a river into the sea; such are the Frith of Forth, or of Edinburgh, the Frith of Clyde, &c.

FRITILLARIA, **FRITILLARY**, a genus of the monogynia order, and hexandria class of plants; natural order Coronaria. Corolla hexapetalous, campanulated, with a nectariferous cavity above the heel in each petal; stamina as long as the corolla. There are five species, all bulbous-rooted flowery perennials, having many varieties.

FRITZLAR, a town of Italy, in the kingdom of Westphalia, on the Eder, 13 miles S.S.W. of Cassel.

FRIUOLI, a province of in the late republic of Venice, bounded on the north by the Tirol and Carinthia; east by

Carniola and Gradisca; south by the Adriatic, and west by the Trevisan, Feltrin, and Bellunese. It is divided into the diocese of Udina and Concordia. Udina is the capital.

FRIZE, in architecture. See **FRIEZE**.

FRIZE, in commerce. See **FRIEZE**. Of frizes, some are crossed, others not: the former are chiefly of English manufacture; the latter of Irish.

FRIZING OF CLOTH, a term in the woollen manufactory, applied to the forming of the nap of stuff into a number of little hard burrs or prominences, covering almost the whole ground thereof.

FROBENIUS, **JOHN**, a famous and learned printer of the sixteenth century, born at Hamelburg in Franconia. He studied in the university of Basil, where he acquired great reputation for learning, and setting up a printing-house in that city, was the first of the German printers who brought that admirable art to any degree of perfection. Being a man of great probity and piety, he would never, for the sake of profit, suffer libels or any thing that would hurt the reputation of another, to go through his press. The great character of this printer, was the principal motive which induced Erasmus to reside at Basil, in order to have his own works printed by him. A great number of valuable books were printed by him with care and accuracy. He died in 1527. Erasmus wrote his epitaph in Greek and Latin. John Frobenius left a son named Jerome Frobenius, and a daughter married to Nicholas Episcopus; who, joining in partnership, continued Frobenius's printing-house with reputation, and printed correct editions of the Greek fathers.

FROBISHER, or **FORBISHER**, **SIR MARTIN**, an excellent navigator and sea-officer in the sixteenth century, born at Doncaster in Yorkshire, and from his youth brought up to navigation. He was the first Englishman who attempted to find a N. W. passage to China, and in 1576, he sailed with two barks and a pinnace for that purpose. In this voyage he discovered a cape, to which he gave the name of Queen Elizabeth's Foreland, and the next day discovered a strait to which he gave his own name. This voyage proving unsuccessful, he attempted the same passage in 1577; but discovering some ore in an island, and his commission directing him only to search for ore, he returned to England with it. He sailed again with fifteen ships and a great number of adventurers, to form a settlement; but being obstructed by the ice, and driven out to sea by a violent storm, they, after encountering many difficulties, returned home, without making any settlement; but with a large quantity of ore. He afterwards commanded the *Aid* in Sir Francis Drake's expedition to the West Indies, in which St. Domingo, Cartagena, and Santa Justina, in Florida, were taken and sacked. In 1588, he bravely exerted himself against the Spanish armada, when he commanded the *Triumph*, one of the largest ships in that service: and as a reward for his distinguished bravery, received the honour of knighthood, from the lord high-admiral at sea. He afterwards commanded a squadron which cruised on the Spanish coast; and in 1592, took two valuable ships and a rich carrac. In 1594 he was sent to the assistance of Henry IV. king of France, against a body of the Leaguers and Spaniards, who had strongly entrenched themselves at Croyzon near Brest; but in an assault upon that fort, on the seventh of November, he was unfortunately wounded with a ball, of which he died soon after he had brought back the fleet to Plymouth, and was buried in that town.

FROBISHER'S STRAITS, a narrow sea, S. of Cape Washington; W. of Davis's Strait, and N. of Cape Farewell in West Greenland.

FRODINGHAM, or **FRODLINGHAM**, a town of Yorkshire, 36 miles E. of York.

FRODSHAM, a town of Cheshire, noted for its ancient castle. It is 10 miles N. E. of Chester.

FROG, in zoology. See **RANA**.

FROME, a river of England, that rises from several springs in the S. W. of Dorsetshire, and falls into Poolhaven, near Wareham.

FROME, or **FROME SELWOOD**, a town of Somersetshire, and the chief town of this part of the country, which was anciently one great forest, called Selwoodshire. It is thirteen miles S. of Bath.

FROMISTA, a town of Spain, in the province of Leon, 18 miles N. of Valencia.

FRONDESCENTIA, [from *frons*, a leaf,] in botany, the unfolding

folding of the leaves of plants. It is also used, by ellipsis, for the time of unfolding.

FRONSAC, a town of France, in the department of the Gironde, and late province of Guienne, 22 miles N. E. of Bourdeaux.

FRONT, in anatomy, the forehead, or that part of the face above the eyebrows. The Latin *frons*, is derived by Martinus from the Greek *φρονειν*, to think, or perceive: of *φρων*, the mind or thought.

FRONT, in architecture, denotes the principal face or side of a building, or that presented to their chief aspect or view.

FRONTAL, in architecture, a little front on, or pediment sometimes placed over, a small door, or window.

FRONTAL, **FRONTLET**, or **BROW-BAND**, in the Jewish ceremonies, consists of four several pieces of vellum, on each of which is written some text of scripture.

FRONTIERS, the extremes of a kingdom or country, which the enemies find in front when they would enter it. They were anciently called *Marches*.

FRONTIGNAC, **FRONTIGNAN**, or **FRONTIGNIAC**, a town of France, in the department of Herault, and late province of Languedoc, famous for its excellent wines. It is 12 miles S. S. W. of Montpellier.

FRONTINAC, **Fort**, a fortress of Canada, on the N. W. side of Lake Ontario, three miles from its mouth, and 300 from Quebec.

FRONTINUS, **SEXTUS JULIUS**, an ancient Roman author, of consular dignity, who flourished under Vespasian, Titus, Domitian, Nerva, and Trajan. He commanded the Roman armies in Britain; was made city-prætor when Vespasian and Titus were consuls; and curator of the aqueducts by Nerva, which occasioned his writing *De Aquæductibus Urbis Romæ*. He wrote four books upon the Greek and Roman art of war; a tract *De Re Agraria*, and another *De Limitibus*. These have been often separately printed; but were all collected together in a neat edition at Amsterdam, in 1661, with notes by Robert Keuchen. He died under Trajan.

FRONTIS OS, in anatomy, called also *os coronale*, the bone of the forehead. See *ANATOMY*.

FRONTISPIECE OF A BOOK, an ornament with an engraved title on the first page, or more properly an emblematical engraved device fronting the title-page.

FRONZELLA, one of the 17 almost inaccessible passes through the mountains of Vicenza, in Maritime Austria, commencing in the valley of Brenta.

FROSE, a town of Upper Saxony, in the duchy of Magdeburg, 10 miles S. of Magdeburgh.

FROSSAY, a town of France, in the department of Lower Loire, 4½ miles S. E. of Painbœuf.

FROST, or **FREEZING**, in physiology, is such a state of the atmosphere, as occasions the congelation or freezing of water and other fluids. See *FREEZING*. Under the articles *COLD*, *CONGELATION*, *EVAPORATION*, *FLUIDITY*, and *FREEZING*, it is shewn, that water and other fluids are capable of containing the element of fire or heat in two very different states. In the one, they seem to imbibe fire in such a manner, that it eludes all the methods by which we are accustomed to observe it, either by our sensation of feeling, or the thermometer; in the other, it manifests itself obviously to our senses, either by the touch, the thermometer, or the emission of light. In the first of these states, we call the body cold; and are apt to say that this coldness is occasioned by the absence of heat. But this mode of expression is not strictly just, for even those fluids which are coldest to the touch contain a vast deal of heat. Thus vapour, which is colder to the touch than the water from which it was raised, contains an immense quantity of fire. The same may be said of common salt, and snow, or ice. If a quantity of each of these substances is separately reduced to 28° or 30° of Fahrenheit's thermometer, upon mixing them together, the heat which could have raised the thermometer to the degree above-mentioned, now enters into the substance of them in such a manner that the mercury falls down to 0. Here an excessive degree of cold is produced, and yet we are sure that the substances contain the very same quantity of heat that they formerly did; nay, they will even seem exceedingly cold, when they most certainly contain a great deal more heat than they ori-

ginally did; for they absorb it from all bodies around them; and if a small vessel full of water is put in the middle of such a mixture, it will in a short time be full of ice. It appears, therefore, that our senses, even when assisted by thermometers, can only judge of the state in which the element of fire is with relation to the bodies around us, without regard to the quantity contained in them. Thus, if heat flows from any part of our body into any substance actually in contact with it, the sensation of cold is excited, and we call that substance cold; but if it flows from any substance into our body, the sensation of heat is excited, and we call that substance hot, without regard to the absolute quantity contained in either case. See *CALORIC*. Of all known substances, the atmosphere either absorbs or throws out heat with the most remarkable facility: and in one or other of these states it always is with respect to the surface of the earth, and such bodies as are placed on or near it; for these, properly speaking, have no temperature of their own, but are entirely regulated by that of the atmosphere. When the air has been for some time absorbing the heat from terrestrial bodies, a frost must be the undoubted consequence, for the same reason that water freezes in a vessel put into a freezing mixture: and were this absorption to continue for a length of time, the whole earth would be converted into a frozen mass. There are, however, certain powers in nature, by which this effect is always prevented; and the most violent frost we can imagine must always, as it were, defeat its own purposes, and end in a thaw. To understand this subject, we must observe, 1. In that state of the atmosphere which we denominate frost, there is a most intimate union between the air and the water it contains; and therefore frosty weather, except in very high latitudes, is generally clear. 2. When such an union takes place, either in winter or summer, we observe the atmosphere also inclined to absorb heat, and consequently to grow frosty. Thus in clear settled weather, even in summer, though the day be excessively hot by the continued sunshine, yet the mornings and evenings are remarkably cold, and sometimes even disagreeably so. 3. The air being therefore always ready in the time of frost or in clear weather, to absorb heat from every substance which comes into contact with it, it follows that it must also absorb part of that which belongs to the vapours contained in it. 4. Though vapour is capable of becoming much colder than water without being frozen, yet by a continued absorption it must at last part with its latent heat, *i. e.* that which essentially constitutes it vapour; and without which it is no longer vapour, but water or ice. No sooner, therefore, does the frost arrive at a certain pitch, than the vapours, everywhere dispersed through the air, give out their latent heat: the atmosphere then becomes clouded: the frost either goes off, or becomes milder, by the great quantity of heat discharged into the air; and the vapours descend in rain, hail, or snow, according to the particular disposition of the atmosphere at the time. 5. Even in the polar regions, where it may be thought that the frost must increase beyond measure, there are natural means for preventing its running to extremes. The principal cause here is, the mixture of a great quantity of vapours from the temperate regions of the globe with the air in those dreary climates. It is well known, that aqueous vapour always flies from a warm to a colder place. For this reason, the vapours raised by the sun in the more temperate regions of the earth, must continually fly northward and southward in great quantities. Thus they furnish materials for those immense quantities of snow and ice which are to be found in the neighbourhood of the poles, and which we cannot imagine the weak influence of the sun in these parts capable of raising. It is impossible that a quantity of vapour can be mixed with frosty air, without communicating a great deal of heat to it; and thus there are often thaws of considerable duration even in those climates where, from the little influence of the sun, we should suppose the frost would be perpetual. 6. We may now account with some probability for the uncertain duration of frosts. In Britain they are seldom of a long continuance; because the vapours raised from the sea with which our island is surrounded, perpetually mix with the air over it, and prevent a long duration of the frost. For the same reason, frosts are never of such long duration in maritime places on the continent as in the inland ones. There is nothing, however, more uncertain than the motion of the vapours with which the air is constantly filled; and therefore it is impossible to prognosticate the duration of a frost with any degree of certainty.

certainty. In general, we may always be certain, that if a quantity of vapour is accumulated in any place, no intense frost can subsist in that place for any length of time; and by whatever causes the vapours are driven from place to place, by the same causes the frosts are regulated throughout the whole world. See VAPOUR. Frost, being derived from the atmosphere, naturally proceeds from the upper parts of bodies downwards, as the water and the earth: so, the longer a frost is continued, the thicker the ice becomes upon the water in ponds, and the deeper into the earth the ground is frozen. In about 16 or 17 days frost, Mr. Boyle found it had penetrated 14 inches into the ground. At Moscow, in a hard season, the frost will penetrate two feet deep in the ground; and Capt. James found it penetrated 10 feet in Charlton island, and the water in the same island was frozen to the depth of six feet. Scheffer assures us, that in Sweden the frost pierces two cubits or Swedish ells into the earth, and turns what moisture it finds there into a whitish substance, like ice; and standing waters to three ells, or more. The same author also mentions sudden cracks in the ice of the lakes of Sweden, nine or ten feet deep, and many leagues long; the rupture being made with a noise not less loud than if many guns were discharged together. By such means, however, the fishes are furnished with air; so that they are rarely found dead. The natural history of frosts furnish very extraordinary effects. The trees are often scorched and burnt up, as with the most excessive heat, in consequence of the separation of water from the air, which is therefore very drying. In the great frost in 1683, the trunks of oak, ash, walnut, &c. were miserably split and cleft, so that they might be seen through, and the cracks often attended with dreadful noises like the explosion of fire-arms. Philos. Trans. Number 165. The close of the year 1708, and the beginning of 1709, were remarkable throughout the greatest part of Europe, for a severe frost. Dr. Derham says, it was the greatest in degree, if not the most universal in the memory of man; extending through most parts of Europe, though scarcely felt in Scotland or Ireland. In very cold countries, meat may be preserved by the frost six or seven months, and prove tolerably good eating. See Captain Middleton's observations made in Hudson's Bay, in the Philos. Trans. Number 465, sect. 2. In that climate the frost seems never out of the ground, it having been found hard frozen in the two summer-months. Brandy and spirits, set out in the open air, freeze to solid ice in three or four hours. Lakes and standing waters, not above 10 or 12 feet deep, are frozen to the ground in winter, and all their fish perish. But in rivers where the current of the tide is strong, the ice does not reach so deep, and the fish are preserved. Id. ib.

FROTH-SPIT, or CUCKOW-SPIT, a name given to a white froth, or spume, very common in spring and the first months of summer, on the leaves of certain plants, particularly on those of the common white field lychnis, or catchfly, thence called by some spatling-poppy. It is formed by a little leaping animal, called by some the flea-grasshopper, by applying its anus close to the leaf, and discharging thereon a small drop of a white viscous fluid, which, containing some air in it, is soon elevated into a small bubble: before this is well formed, it deposits such another drop; and so on, till it is every way overwhelmed with a quantity of these bubbles, which form the white froth which we see. Within this spume it is seen to acquire four tubercles on its back, wherein the wings are inclosed: these bursting, from a reptile it becomes a winged animal; and thus rendered perfect, it flies to meet its mate, and propagate its kind. It has an oblong obtuse body; a large head with small eyes; four external wings, of a dusky brown colour, marked with two white spots: the head is black. It is a species of Cicada.

FRUTESCENCIA, [from *fructus*, Lat. fruit,] in botany, literally signifies the growth of the fruit, but is used elliptically for the precise time in which, after the fall of the flowers, the fruits arrive at maturity, and disperse their seeds. In general, plants which flower in spring ripen their fruits in summer, as rye; those which flower in summer have their fruits ripe in autumn, as the vine; the fruit of autumnal flowers ripens in winter, or the following spring, if kept in a stove or otherwise defended from excessive frosts. These frosts, says M. Adanson, are frequently so pernicious and violent, as to destroy the greatest part of the perennial plants of Virginia and Mississippi, that are cultivated in France, even before they have exhibited their fruit. The plants which flower

during our winter, such as those of the Cape of Good Hope, ripen their fruit in spring, in our stoves.

FRUCTIDOR, [*i. e.* the fruit-month, from *fructus*, Lat.] the name of the 12th month, in the late French Revolutionary Calendar. It began Aug. 19, and ended Sept. 16.

FRUCTIFICATION OF PLANTS, is defined by Linnæus to be the temporary part of a vegetable appropriated to generation, terminating the old vegetable, and beginning the new. See BOTANY.

FRUIT, in its general sense, includes whatever the earth produces for the nourishment of animals, expressed by the Latins under the name *fruges*, as herbs, grain, hay, corn, &c.

FRUIT, in botany, called by the Greeks, *καρπός*, in the Linnæan system, is one of the parts of fructification, and is distinguished into three parts, viz. the pericarpium, seed, and receptacle, or receptaculum seminum. See BOTANY. Fruit, more properly, signifies the production of a tree, or plant, for the propagation of its kind, in which sense the word takes in all kinds of seeds, with their furniture.

FRUITS, in commerce, are distinguished into recent or fresh, and dry.

1. FRUITS, DRY, are those dried in the sun, or by the fire, with other ingredients sometimes added to make them keep; imported chiefly beyond sea, and sold by the grocers. Such are raisins, currants, figs, capers, olives, cloves, nutmegs, pepper, and other spices; which see in their order. Under the denomination of dry fruits are also frequently included apples, pears, almonds, filberds, &c.

2. FRUITS, FRESH, OR RECENT, are those sold just as they are gathered from the tree, without any farther preparation; as are most of the productions of our gardens and orchards, sold by the fruiterers.

FRUIT, PRESERVATION OF. In the Philosophical Transactions, No. 237, we have a receipt for preserving fruit and flowers for a whole year, which is as follows. Take saltpetre, one pound; bole armoniac, two pounds; common clean sand, three pounds: mix them together; and, in dry weather, take fruit or flowers of any sort, not fully ripe, each with its stalk, and put them singly into an open glass, till it be full; cover it close with oil-cloth; and in a dry cellar, put each of these glasses four fingers-deep under ground, so that quite round above, as well as below, there may remain two fingers-thick of the mixture. One of the most easy methods of preserving fruit, is that of depositing it in ice-houses, where it may remain in a frozen state for a considerable time. And, if the fruit be afterwards gradually thawed, by covering it with melted ice, or immersing it in cold spring-water, it will lose but little of its flavour, provided it be consumed on the same day. Fruit may also be preserved, by keeping it in pits dug in a dry soil, or in dry cellars, or even in barns, if the temperature be between 32° and 48° of Fahrenheit's thermometer; that is, such as will neither induce frost nor vegetation. These pits or magazines, however, ought to be covered with such materials as are calculated to repel heat, and to absorb any accidental putrid exhalations, and thus retard the progress of putrefaction. Hence Dr. Darwin recommends the fruit to be covered first with pulverized charcoal, one or two inches thick, over which is to be laid a stratum of saw-dust, and over the latter, a thick, impenetrable thatch of straw: thus, seeds and fruits may be stored up for ages, without vegetating or decaying. He likewise mentions another mode of preserving fruit, by heat. As fermentation will not commence in the heat of boiling water, or 212°; and, as that degree of temperature can be easily procured by steam, or by the vicinity of vessels containing boiling water, he is of opinion, that such fruits as are used for culinary purposes throughout the year, may be kept in a fresh state, by putting them into bottles, and exposing them to the wasted steam of engines; or, by immersing them in the hot water that flows from such steam when condensed; or, by placing the bottles near the boilers which are fixed beside kitchen-fires.

FRUITERY, a place for the keeping of fruit; a fruit-house or fruit-loft. A fruitery should be inaccessible to any thing of moisture, and should be as much as possible so, even to frost.

FRUIT-TREES, are such as bear fruit, namely, Apple, Cherry, Pear-trees, &c. With regard to fruit-trees it may be observed, 1. The cutting or pruning them when young hinders their bear-

ing, though it contributes to the richness and flavour of the fruit as well as to the beauty of the tree. 2. Kernel fruit-trees come later to bear than stone fruit-trees: the time required by the first, before they come to any fit age for bearing, being on an average five years; but when they do begin, they bear in greater plenty than stone-fruit. 3. Stone-fruit, figs, and grapes, commonly bear considerably in three or four years, and bear full crops the fifth and sixth years; and hold it for many years, if well ordered. 4. Fruit-trees in the same neighbourhood will ripen a fortnight sooner in some grounds than in others of a different temperature. 5. In the same country, hot or cold summers set considerably forwards, or put backwards, the same fruit. 6. The fruit on wall-trees generally ripen before those on standards, and those on standards before those on dwarfs. 7. The fruit of all wall-trees planted in the S. and E. quarters, commonly ripen about the same time, only those in the S. rather earlier than those in the E.; those in the W. are later by 8 or 10 days; and those in the N. by 15 or 20. While young, no trees should be suffered to bear a large quantity of fruit; and, if they abound with blossoms, the fruit should be gathered as soon as it is formed; leaving only half a dozen of the produce, to ascertain its size and quality. By this measure, the trees will not only produce larger and finer fruit, but, by being kept clear, the leading and collateral branches will every year become more vigorous. Nor ought any young plant, or newly-engrafted tree, to be permitted to run mopeheaded, as it will make no progress, till each branch has acquired a determined leader: for, if the growth of a tree be prevented, it will be extremely difficult to throw such energy into the system, as to enable it to grow freely. As long as fruit-trees continue in the nursery, it will be requisite to cut down the head, in order to give strength and symmetry to the stem: it will also be useful to shorten most of the grafts, lest they should be blown out by the wind: these operations likewise contribute to swell the buds. The ingenious Mr. Bucknall particularly recommends, not to place the rows of trees in a situation either directly north or south, but rather inclining to the east, as the sun will then shine upon them in the early part of the day during the spring, and thus dissipate the vapours collected in the night; which if suffered to condense, will stunt the fruit in the earlier stages of its growth. He farther observes, that if the shaws (or shades) be properly attended to, the trees being placed in this position, will be enabled to withstand the power of the winds; nor will they be affected by blight. The shaw will also protect the fruit from the autumnal winds, by which half the crop of fruit is not unfrequently blown down, before it is ripe; and, as the heads are at that season of the year laden with fruit and leaves, many trees are torn up from the ground, or so lacerated as to be completely spoiled; a misfortune that might be effectually prevented by a proper disposition of the shades. In the Transactions of the Economical Society of Leipzig, we meet with a communication from the Rev. Mr. Germershausen, on the means of promoting the growth of young fruit-trees, especially in grass-land. This method simply consists in spreading flax-shows, or the refuse of flax, after it has been combed, on the soil contiguous to the trunks of the trees, as far as the roots extend; by which means their size as well as their fertility is remarkably increased. He mentions an instance, where an old plum-tree which, being in a languishing state, in a grass-field, was treated in the manner above-directed, and thus not only acquired a new bark, but produced larger, and better-tasted fruit: the young shoots also, which formerly grew up around the stem, were prevented from sprouting forth, because the refuse of the flax excluded the access of air to the trunk, and imparted additional nutriment to the roots. The leaves falling from the trees in autumn, may be substituted for the flax-shows, if these cannot be easily procured; but it will be necessary to dig a small trench for the reception of the decayed leaves, and also to cover them with tiles, flat stones, or a log of wood, to prevent their dispersion by the wind. This precaution, however, is not required with the refuse of flax, which adheres so closely to the soil, as to withstand the most violent storm. Although gardeners bestow the strictest attention on orchards, it sometimes happens that the bark of trees is stripped off by sheep, or by other accidents. In this case, it has been recommended by Mr. W. Fairman, of Miller's House, Lynsted, Kent, to take off the arms of such trees as are damaged; to cut slips off the rind, about two or three inches in width, and to place four or five of them perpendicularly round the naked part.

The damaged rind is previously to be cleared away, the sound bark somewhat raised, and the slips inserted beneath it, to promote the circulation of the sap. These dressings are next to be bound very tight with rope-yarn; and a composition of loam and cow-dung, together with a small proportion of drift-sand, should be applied, over which some old sacking, or similar stuff, ought to be fastened. Mr. Fairman adds, that he made an experiment with this mode of treatment, in the spring of 1794, on some trees which had been much damaged by sheep, and that it completely succeeded, the slips adhering closely, and being full of sap. Fruit-trees, like the rest of the vegetable creation, are the prey of a variety of insects, of which few are more destructive than those infesting apple, pear, cherry, oak, white-thorn, and similar trees. They deposit their black eggs in clusters, resembling withered leaves, and which are twisted by a cobweb round the uppermost branches. These notorious insects are hatched in the spring, when they assume the form of very diminutive caterpillars, which destroy every thing before them, and rapidly propagate in the most unfavourable weather. They damage oaks very materially; devour the white-thorn, and kill the plant; apples and pears, likewise, receive great injury. The only remedy hitherto known of exterminating such noxious vermin, is to cut off all the twigs or shoots of every tree on which these nests of insects appear; to collect them in a heap, and burn them as soon as the weather will permit; for, where this necessary operation is deferred till the summer approaches, the insects increase prodigiously, and commit irreparable damage. The disorders to which fruit-trees are subject, are various; the most fatal are Blight, Canker, Mildew, Moss, &c. to which we refer. The effects of frost are likewise often fatal, especially to the more tender fruit-trees. With a view to obviate such damage, different methods have been suggested. In a communication from a Swedish agriculturist to a respectable periodical work, published on the Continent, the following expedient is stated to have been successfully employed, to protect fruit-trees from the vernal frosts. As soon as the weather begins to grow cold in autumn, large quantities of water are to be poured on the trunks of such trees, so that they may receive an early impression of the cold. In the spring, snow is to be accumulated round their stems; which retards vegetation, and prevents them from blossoming too early. In consequence of this irrigation, the buds shoot forth at a period, when no apprehension need be entertained from the attacks of the frost that frequently happens during the nights of spring.—Such practice of watering the borders of trees, is said to increase the heat in them, by accelerating the motion of their juices; if the soil of such border has been properly opened and prepared. It is farther recommended, to add one ounce of common salt to every gallon of water, where those borders are old, and have been impoverished by producing many successive crops; or if they have been manured with dung not sufficiently putrefied. The following method of making fruit grow, during winter, is abstracted from the ninth vol. of the Annual Register for 1763: Let the trees be taken up by the roots in the spring, at the time they are about to bud; carefully preserving some of their own soil among the roots. These are to be placed upright in a cellar till Michaelmas, when they are to be put into vessels with the addition of fresh earth, and deposited in a stove or hot-house, being regularly moistened every morning with rain-water, in which sal-ammoniac has been dissolved, in the proportion of one ounce to a quart. Thus, in the month of February, the fruit will appear. The same method is applicable to rose-trees, and flowers; which last, when sown in pots at or before Michaelmas, and watered in a similar manner, will blow towards the end of December. In order to ascertain when fruits, for instance, apples and pears, are sufficiently ripe to be gathered, it is requisite to attend to the colour of the skin inclosing the seeds. During their infant state, there is no cavity round the kernels, but they are in contact with the seed-vessel. In a subsequent period, when the fruit has exhausted the nutritious matter, the cells containing the seeds become hollow, and the latter assumes a dark colour. This, Dr. Darwin observes, is the proper criterion by which to judge when such fruits should be gathered; as it indicates that they will not continue to increase in size, but waste and become hollow, by absorbing the mucilaginous particles from the centre. Among the various distinct publications which have appeared on this subject, the following are allowed to possess considerable merit: "A Treatise on Fruit-trees," &c. by Thomas Hitt;

Hitt; 8vo. 2d. edition, 1768;—and “The British Fruit-Gardener, and Art of Pruning,” &c. by Thomas Abercrombie; 8vo. 1779.

FRUITS, COLOURS FROM. The red juices of currants, mulberries, elder-berries, black-cherries, and other fruit, impart their tinging particles to water, but more completely to rectified spirits; and the tincture acquires a brighter colour. The red watery solutions, as well as the juices, are sometimes rendered dull, and sometimes more lively, by means of acids; they generally acquire a purplish hue, by the addition of alkalies. The greater part of the colours of these juices is perishable, though they strongly resist fermentation, and continue almost unchanged, when the liquor is converted into wine. If the juice be thinly spread upon other bodies, exsiccated, and exposed to the air, the colour speedily decays; the bright red fades sooner than any other; but the dark dull red obtained from the juice of the black-cherry, is of considerable durability. The ripe berries of the buck-thorn tinge paper of a green colour: when green, those berries afford a yellow, and if ripe, a purplish pigment. The injudicious practice of promiscuously allowing fruit, whether ripe or unripe, to children and infants, is very reprehensible. On account of its acidity, they are not able to bear it in excess; and their digestive powers become so frequently impaired at the expence of other secretions; such as insensible perspiration, and the discharges by stool, both of which are thus unnaturally promoted. All fruit given to young people, ought to be perfectly ripe: mothers and nurses should likewise bestow especial attention on the cleanliness of the peels, or shells, which, as they generally pass through different hands, or may have been stored in improper places, require to be previously wiped or washed.

FRUMENTACEOUS is applied by botanists to all such plants as have a conformity with wheat, in their fruits, leaves, ears, or the like.

FRUMENTARIJ, a kind of soldiers or archers under the western Roman empire. The first mention we find made of these officers is in the reign of the emperor Adrian, who made use of them to inform himself of whatever passed.

FRUMENTATION, in Roman antiquity, a largess of corn bestowed on the people.

FRUSH, a sort of tender horn that grows in the middle of the sole, and at some distance from the toe: it divides into two branches, running towards the heel, in the form of a fork. See **FARRIERY**.

FRUSTUM, in mathematics, a part of some solid body separated from the rest. Thus,

1. The **FRUSTUM OF A CONE** is the part that remains when the top is cut off by a plane, parallel to the base; and is otherwise called a truncated cone.

2. The **FRUSTUM OF A GLOBE, OR SPHERE**, is any part thereof cut off by a plane, the solid contents of which may be found by this rule: To three times the square of the semidiameter of the base add the square of its height; then multiply that sum by the height, and this product, multiplied by $\frac{1}{162}$ gives the solidity of the frustum.

3. The **FRUSTUM OF A PYRAMID** is what remains after the top is cut off by a plane parallel to its base. As a general theorem: in the frustum of any solid, generated by the revolution of any conic section about its axis: if to the sum of the two ends be added four times the middle section, then the last sum divided by six will be the mean area, and being drawn into the altitude of the solid will produce the content: That is A and a being the areas of the ends, and M equal the middle section; then we have

$$\frac{A + a + 4M}{6} \times h = \text{solid content.}$$

This theorem holds good for complete solids as well as frustums, whether right or oblique, and not only of the solids generated from the conic sections, but also of all pyramids, cones, and in short of any solid, whose parallel sections are similar figures. See **MENSURATION**.

FRUTEX, a **SHRUB**. Shrubs, according to Linnæus, make a branch of the seventh family in the vegetable kingdom; and are distinguished from trees, in that they come up without buds. But this distinction is not universal, though it be generally just with regard to those of Europe. Nature has made no absolute distinc-

tion between trees and shrubs. **Frutex**, in its general acceptation, is a plant whose trunk is perennial, gemmiparous, woody, dividing and subdividing into a great number of branches. In short, it is the epitome of a tree, exemplified in the rose-bush.

FRUTINGEN, a town of the Helvetic republic, in the late canton of Bern, 30 miles S. E. of Friburg.

FRUTIS, [from *fruor*, to enjoy,] a name of Venus.

FUCHSIA, in botany, a genus of the octandria monogynia class and order. Calyx one-leaved, coloured, bearing the corolla, very large; petals four, small; berry inferior, four-celled, with many seeds. There are five species.

FUCINUS, in ancient mythology, the god of the lake so named. His temple stood on its banks.

FUCINUS LACUS, in ancient geography, a lake of Italy in the country of the Marsi, now called Celano, from a cognominal citadel, in the S. of Abruzzo-Ultra.

FUCUS, in antiquity, a name given to certain dyes and paints; particularly to a purple sea-plant used to dye woollens and linens of that colour. The dye, says Theophrastus, was very beautiful, but not lasting; for it soon began to change, and in time went wholly off. The women also used something called fucus, to stain their cheeks red; and many have supposed, from the same word expressing both, that the same substance was used on both occasions. But this, on a strict inquiry, proves not to be the case. The Greeks called every thing *poros*; that would stain or paint the flesh. But this peculiar substance used by the women to paint their cheeks, was distinguished from the others by the name of rizon among the more correct writers, from *ρίζα*, a root; and was indeed a root brought from Syria into Greece.

FUCUS, in botany, a genus of the cryptogamia algæ. Male vesicles smooth, hollow, with villose hairs within, interwoven; female vesicles smooth, filled with jelly, sprinkled with immersed grains, prominent at the tip. Seeds solitary. This genus comprehends most of those plants which are commonly called seaweeds; more than seventy species are enumerated; they may all be used to manure land, or burnt for alkali. Some of the species are eaten, either fresh out of the sea; or boiled tender, with butter, pepper, &c. If the *F. saccharinus* is washed in spring-water, and then hung up in a warm place, a substance like sugar exudes from it.

F. CILIATUS, the **CILIATED OR LIGULATED FUCUS**, is found on the shores of Iona and other places, but is not common. The colour is red, the substance membranous and pellucid, without rib or nerve; the ordinary height of the whole plant about four or five inches. It is variable in its appearance, according to the different stages of its growth. It is eaten by the Scots and Irish promiscuously, with dilse.

F. PALMATUS, the **PALMATED OR SWEET FUCUS**, commonly called *dulse* or *dilse*, grows plentifully on our sea-coasts and islands. Its substance is membranaceous, thin, and pellucid; the colour red, sometimes green with a little mixture of red; its length generally about five or six inches, but varies from three to twelve: it is fan-shaped, or gradually dilated from the base upwards. Its divisions are extremely various. The inhabitants both of Scotland and England take pleasure in eating this plant: and women of weak habits often recover an appetite by eating it raw.

FUEGO, or **FOGO**, one of the Cape de Verd Islands, in the Atlantic, so named from its volcano; and called also St. Philip, from its having been discovered on St. Philip's day. Lon. 24. 20. W. Lat. 15. 10. N.

FURGO, or **TERRA DEL FUEGO**, a large island, separated from the S. extremity of America, by the Straits of Magellan. It consists of a chain of stupendous mountains, some of which are volcanoes, covered with perpetual snow; notwithstanding which the inhabitants go naked, and paint their bodies, which are naturally fair.

FUEL. Dr. Black divides fuels into five classes; the first comprehends the fluid inflammable bodies; the second, peat or turf; the third, charcoal of wood; the fourth, pit-coal charred; and the fifth, wood, or pit-coal, in a crude state, and capable of yielding a copious and bright flame. The fluid inflammables are considered as distinct from the solid, on this account, that they are capable of burning upon a wick, and become in this way the most manageable sources of heat; though, on account of their price, they are never employed for producing it in great quantities;

ties; and are only used when a gentle degree, or a small quantity of heat is sufficient. The species which belong to this class are alcohol and different oils. Alcohol, when pure and free of water, is as convenient and manageable a fuel for producing moderate or gentle heats as can be desired. Its flame is perfectly clean, and free from any kind of soot; it can easily be made to burn slower or faster, and to produce less or more heat, by changing the size or number of the wicks upon which it burns; for as long as these are fed with spirit, in a proper manner, they continue to yield flame of precisely the same strength. The cotton, or other materials, of which the wick is composed, is not scorched or consumed in the least, because the spirit with which it is constantly soaked is incapable of becoming hotter than 174°, Fahrenheit, which is considerably below the heat of boiling water. It is only the vapour that arises from it which is hotter, and this too only in its outer parts, that are most remote from the wick, and where only the combustion is going on, in consequence of communication and contact with the air. At the same time, as the alcohol is totally volatile, it does not leave any fixed matter which, by being accumulated on the wick, might render it foul and fill up its pores. The wick, therefore, continues to imbibe the spirit as freely, after some time, as it did at the first. The second kind of fuel mentioned, peat, is so spongy that, compared with the more solid fuels, it is unfit to be employed for producing very strong heats. It is too bulky for this: we cannot put into a furnace, at a time, a quantity that corresponds with the quick consumption that must necessarily go on when the heat is violent. However, when we desire to produce and keep up, by means of cheap fuel, an extremely mild gentle heat, we can hardly use any thing better than peat. But it is best to have it previously charred, that is, scorched, or burnt to black coal. The next fuel, in order, or the charcoal of wood, is the chief fuel used by the chemists abroad, and has many good properties. It kindles quickly, emits few watery or other vapours while burning, and when consumed leaves few ashes, and those very light. They are, therefore, easily blown away, so that the fire continues open, or pervious to the current of air which must pass through it to keep it burning. This sort of fuel, too, is capable of producing as intense a heat as can be obtained by any; but in those violent heats it is quickly consumed, and needs to be frequently supplied. Fossil-coals charred, called cinders, or coaks, have, in many respects, the same properties as charcoal of wood; as kindling more readily in furnaces than when they are not charred, and not emitting watery, or other gross smoke, while they burn. This sort of charcoal is even greatly superior to the other in some properties. The fifth and last kind of fuel is wood, or fossil-coals, in their crude state, which it is proper to distinguish from the charcoals of the same substances. The difference consists in their giving a copious and bright flame, when plenty of air is admitted to them, in consequence of which they must be considered as fuels very different from charcoal, and adapted to different purposes. See FLAME. The fuel generally used for common purposes in Britain is pit-coal: it is attended with considerable expence, which is not a little increased by the enormous waste, arising from the injudicious manner in which the fires are usually managed. Hence different compositions have been proposed, among which that contrived by Count Rumford more particularly claims our attention. It is known by the name of kindling-balls, which are composed of equal parts of coal, charcoal, and clay; the two former are reduced to a fine powder, well mixed and kneaded together with the clay moistened with water; and then formed into balls of the size of hens eggs, which are thoroughly dried. These balls may be made so inflammable as instantly to take fire from the smallest spark, after they have been dipped in a strong solution of nitre, and then dried. With those three ingredients, Count Rumford is of opinion, that a certain proportion of straw, cut very small, or of chaff, or even of sawdust, may be advantageously incorporated. The excellence of the fuel thus prepared consists in its economy and cleanliness; circumstances of the utmost importance, and which are calculated greatly to improve the apartments of the opulent.

FUENHOA, a city of China, in the province of Pe-tcheli, celebrated for its extent and the number of its inhabitants, as well as for the beauty of its streets and triumphal arches.

FUEN-TCHEOU, or **FUEN-TCHEOU-FOU**, a city of China, of the first rank, in the province of Chansi, on the Fuen, 280 miles S. W. of Pekin.

FUENTE GINALDO, a town of Spain, in Estremadura, 16 miles N. W. of Coria.

FUERTEVENTURA, or **FORTAVENTURA**, one of the Canary Islands, consisting of two peninsulas, joined by an isthmus 12 miles broad.

FUESSEN, or **FUSSEN**, a town of Suabia, in the bishopric of Augsburg, on the Lech, 47 miles E. of Augsburg.

FUGALIA, in Roman antiquity, a feast supposed by some to be the same with the Regifugium, held on the 24th of February, in memory of the expulsion of the kings, and the abolition of monarchy.

FUGAM FECIT, is where it is found by inquisition that a person fled for treason or felony; as to which it is agreed, that whosoever a person found guilty by such inquest, either as a principal or as an accessory before the fact, is found also to have fled for the same, he forfeits his goods absolutely, and the issues of his lands, till he is pardoned or acquitted. But wherever the indictment against a man is insufficient, the finding a fugam fecit will not hurt him; and that in all cases the particulars of the goods found to be forfeited may be traversed. 2 Haw. 450.

FUGITIVE, a person obliged to fly his country, or remove from a place where he had some abode, or establishment, on account of his crimes, debts, or other occasions.

FUGITIVE PRECES, in literature, essays, poems, or other short compositions, inserted in newspapers, magazines, or the like periodical publications; or printed on loose sheets or half-sheets; so called, because easily lost and soon forgot.

FUGITIVE'S GOODS, are the proper goods of him that flies, which after the flight lawfully found, belong to the king or lord of the manor. 5 Co. Rep. 109. See FELON'S GOODS.

FUGUE, [from *fuga*, a flight,] in music, a composition either vocal or instrumental, or both, in which one part leads off some determined succession of notes called the subject, which, after being answered in the fifth and eighth by the other parts, is interspersed through the movement, and distributed amid all the parts in a desultory manner, at the pleasure of the composer; sometimes accompanied by other adventitious matter, and sometimes by itself. These are the principal rules of the fugue; of which some are peculiar to itself; and others common to it with what the French call imitation. 1. The subject proceeds from the tonic to the dominant, or from the dominant to the tonic, in rising or descending. 2. Every fugue finds its response in the part immediately following that which commenced. 3. That response ought to resume the subject in the interval of a fourth or fifth above or below the key, and to pursue it as exactly as the laws of harmony will admit; proceeding from the dominant to the tonic when the subject is introduced from the tonic to the dominant, and moving in a contrary direction when the subject is introduced from the dominant to the tonic. One part may likewise resume the same subject in the octave or unison of the preceding; but in that case, it is a repetition rather than a real response. 4. As the octave is divided into two unequal parts, of which the one contains four gradations descending from the tonic to the dominant, and the other only three in continuing the ascent from the dominant to the tonic; this renders it necessary to have some regard to this change in the expression of the subject, and to make some alterations in the response, that we may not quit the cords that are essential to the mode. It is a different case when the composer intends to alter the modulation; for there the exactness of the response itself, when taken in a different tone, produces the alteration proper for this change. 5. The fugue should be planned in such a manner, that the response may commence before the close of the best air, so that both the one and the other may be in part heard at the same time: that, by this anticipation, the subject may be as it were connected with itself, and that the art of the composer may discover itself in this concourse. It is absolute mockery, instead of a fugue, to impose upon the hearers the same air, merely transposed from one key to another, without any other restraint than an accompaniment afterwards formed at pleasure. This deserves at best no better name than what the French call imitation. See IMITATION. Besides these rules, which are fundamental, there are others, which, though prescribed by taste alone, are not less essential. Fugues, in general, render music more noisy than agreeable; for this reason they are most agreeable in the chorus. There are distinct descriptions of fugues; the simple fugue, the double fugue, and the counter fugue. The

FUGUE,

FUGUE, SIMPLE, contains but one subject, is the least elaborate in its construction, and the easiest in its composition.

FUGUE, DOUBLE, consists of two subjects, occasionally intermingled and moving together; and the

FUGUE, COUNTER, is that fugue in which the subjects move in a direction contrary to each other. In all the different species of fugues, the parts fly, or run after each other, and hence the derivation of the general name fugue.

FUIRENA, in botany, a genus of the triandria monogynia class and order; natural order, Calamariæ. Ament imbricate, with awned scales; calyx none; corolla with three petal-shaped obovate glumes, ending in a tendril. One species, *F. paniculata*, a lofty grass of Surinam and Jamaica.

FULCRUM, in mechanics, the prop or support by which a lever is sustained. See **MECHANICS**.

FULCRUM, in botany. See **BOTANY**.

FULDA, or **FULDE**, a late episcopal principality of Germany, in the Upper Rhine.

FULDA, a river which joins the Werra at Minden; they form the Weser.

FULDA, or **FULDE**, the capital of the above late principality, seated on the river, 55 miles S. of Cassel.

FULGORA, in zoology, a genus of the class insecta, order hemiptera. Head hollow, inflated, extended forward; antennæ short, seated beneath the eyes, consisting of two joints, the outer one larger and globular; snout elongated, inflected, four-jointed; legs formed for walking. There are about 25 species, almost all inhabitants of hot climates. *F. Europæa*, has the body green; wings hyaline, reticulate; front conic. This is a small insect, and destitute of the shining quality, by which foreign species are distinguished. *F. lanternaria*, or Peruvian lantern-fly is a very curious and beautiful insect of Surinam, and other parts of South America, which diffuses a very brilliant phosphoric splendor in the dark from its head.

FULICA, in ornithology, the **GALLINULE** and **COOT**, a genus of birds of the order grallæ. Generic character: bill strong, thick, and sloping to the point; upper mandible arched over the lower at the edge, and reaching far up the forehead; nostrils nearly oval; front bald; toes four, long, and furnished with broad scalloped membranes. There are twenty-five species.

F. ATRA-COOT, is distinguished from the gallinule by pinnated feet. It inhabits Europe, Asia, and America, and is about the size of a small fowl. It feeds on small fish and water-insects, is common in some parts of this country at all seasons, but in the breeding season is seen almost always in pairs, about the borders of ponds and lakes well fringed with rushes, of which it mats itself a large nest, said to be often observed floating on the water. These birds are devoured when young by the buzzards, which infest their haunts, and prevent them from that great multiplication which might be otherwise expected. See Plate LVIII.

F. ATERRIMA, the **GREATER COOT**, is of a larger size than the common coot, and its plumage is blacker. This species is found in Lancashire and Scotland; but is more plentiful on the Continent, being found in Russia and the W. of Siberia very common; also at Sologne and the neighbouring parts, where they call it judelie. Its flesh is much esteemed.

FULIGO, in botany, a genus of the cryptogamia fungi class and order. Fungus with a cellular fibrous bark; the fibres penetrating in a reticulate manner through the seminal mass.

FULLER, THOMAS, D. D. a learned English historian and divine, born at Alwinkle, Northamptonshire, in 1608. He studied at Cambridge, and was chosen minister of St. Bennet's there. Upon the restoration, he was appointed chaplain extraordinary to Charles II. and created D. D. His memory was so amazingly tenacious, that he could repeat a sermon, verbatim, if once he heard it. He once undertook, in passing to and from Temple-bar to the Poultry, to tell at his return every sign as it stood in order, on both sides of the way, repeating them either backwards or forwards: and this task he actually performed. He wrote, 1. *A History of the Holy War*. 2. *The Church History of Britain*, in folio. 3. *Andronicus, or the Unfortunate Politician*, in 8vo. 4. *A Pisgah sight of Palestine*. 5. *A History of English Worthies*; and other works. He died in August 1661. He was fond of punning; but once attempting to play off a joke upon a gentleman named Sparrowhawk, he met with a retort in his own stile.

Vol. II.—No. 90.

"What is the difference, said the Dr. (who was very corpulent) between an owl and a sparrowhawk?" "It is, replied the other, fuller in the head, fuller in the body, and fuller all over." Thus he retorted the owl upon him completely.

FULLER, a workman employed in the woollen manufactories, to mill, or scour, cloths, serges, and other stuffs, in order to render them more thick, compact, and durable.

FULLER'S EARTH, or **TERRA FULLONICA**, in natural history, a soft, greyish, brown, dense, and heavy marle: when dry, it is of a greyish, ash-coloured brown, in all degrees from very pale to almost black, and it has generally something of a greenish cast: it is very hard and firm, of a compact texture, of a rough and somewhat dusty surface, that adheres slightly to the tongue: it is very soft to the touch, not staining the hands, nor breaking easily between the fingers: it has a little harshness between the teeth, and melts freely in the mouth: thrown into the water, it makes no ebullition, or hissing, but swells gradually in bulk, and falls into a fine soft powder. It makes no effervescence with aqua-fortis. The greatest quantity, and of the finest quality, is dug in the pits at Wavedon, near Woburn in Bedfordshire. The strata in these pits lie thus: From the surface to the depth of six feet, there are several layers of sand, all reddish, but some lighter-coloured than others. Under these there is a thin stratum of a sand-stone, which they break through, and then they find the fuller's earth. A specimen from Hampshire, analysed by Bergman, contained.

51.8 silica,
25.0 alumina,
3.3 lime,
3.7 oxyd of iron,
0.7 magnesia,
15.5 water.

100.0

This earth is used by fullers to take grease out of their cloth before they apply soap. It is essential to fuller's earth that the particles of silica should be very fine, otherwise they would cut the cloth. Any clay possessed of this property may be considered as fuller's earth; for it is the alumina alone which acts upon the cloth, on account of its strong affinity for greasy substances.

FULLER'S THISTLE, **FULLER'S WEED**, or **TEAZLE**, in botany. See **DIPSACUS**.

FULLERTON POINT, a cape on the W. coast of Antigua, Lon. 61. 35. W. Lat. 17. 13. N.

FULLING, is the art of cleansing, scouring, and pressing cloths, stuffs, and stockings; to render them stronger, closer, and firmer: it is also sometimes called milling. The fulling of cloths, &c. is performed by a kind of water-mill, thence called a fulling, or scouring-mill. Without describing the mechanism of this manufacturing process, we cannot omit to remark that urine is sometimes employed, as well as soap and fuller's earth, to prepare the stuffs for receiving the first impressions of the pester. They are first steeped in urine, then in a solution of fuller's earth and water, and lastly in soap, dissolved in hot water. Soap alone would fully answer this purpose, but it is too expensive, especially as, according to the present mode of dressing, fuller's earth is of equal efficacy. Urine is certainly prejudicial, and ought entirely to be abandoned here, both on account of its disagreeable smell, and its sharp, saline properties, which frequently render the cloths dry and harsh. The scouring of cloth, however, is not the only object in fulling it; the alternate pressure communicated by the pestles, or stampers, to the stuffs, occasions in its advanced stages an effect analogous to that produced upon hats in the operation of felting. Thus, the fibres of wool which compose one of the threads, whether of the warp or the woof, assume a progressive motion, first introducing themselves among those of the contiguous threads, then into those which follow, so that gradually all the threads, both of the warp and the woof, become completely felted. The cloth, after having by this process become contracted, and shortened in its dimensions, partakes in a great measure of the nature of felt: hence it may be cut without being liable to unravel; and consequently there is no necessity to hem its edges. Farther, as the threads of both the warp and woof are more intimately combined, the web, which acquires a greater degree of thickness, likewise forms a warmer clothing. The process of fulling stockings, caps, &c. is performed in a manner somewhat different.

ferent from that in mills; namely, either with the feet or hands; or a kind of rack or wooden machine, armed with teeth of the same materials; or, which is still better, horses' or bullocks' teeth may be substituted. In this operation, urine, green soap, white soap, and fuller's earth, are employed; but the first of these ingredients, for the reasons before stated, is here also detrimental to the texture. Stockings manufactured in a loom, should be filled with soap alone; but, for dressing such as have been knit, earth may likewise be added. Lastly, knit-worsted is by this process rendered less subject to run, if a stitch should happen to drop in the stockings.

FULMINATION, in the Romish canon law, a sentence of a bishop, official, or other ecclesiastic, appointed by the pope, by which it is decreed that some bull sent from the pope shall be executed.

FULMINATION, in chemistry, differs from detonation only in degree, they are both the effects of rapid decomposition accompanied by a loud noise, either with or without flame. See **GOLD**, **MERCURY**, **POWDER**, and **SILVER**.

FUMARIA, in botany, **ENGLISH FUMITORY**, a genus of the diadelphia hexandria class and order. Natural order, Corydalis. Calyx two-leaved; corolla ringent; filaments two, membranaceous, with three anthers on each. There are fifteen species.

F. OFFICINALIS, or **COMMON FUMITORY**, grows naturally in shady cultivated grounds, and produces spikes of purplish flowers in May and June. It is very juicy, of a bitter taste, without any remarkable smell. Its medical effects are, to strengthen the tone of the bowels, gently loosen the belly, and promote the natural secretions.

FUMIGATION, in medicine, denotes the artificial impregnation of the atmosphere, with the fumes or smoke of any vegetable or aromatic substance. By the subtle fumes produced by burning certain substances, much benefit or prejudice may be produced, according to the nature of the case, and the constitution on which the effects are to be exerted; as is evident from the palsies produced among metal-gilders, workers in lead-mines, &c. and also from the benefits received in many cases when the air is impregnated with salutary materials. Catarrhs and colds, for instance, are relieved by fumes received with the breath; by the same means, expectoration is assisted in the asthma; and even ulcers in the lungs have been relieved by this method.

FUNAMBULUS, among the Romans, was what we call a rope-dancer, and the Greeks *schœnobates*.

FUNARIA, in botany, a genus of the cryptogamia musci class and order. Capsule obovate; fringe double; outer, of sixteen oblique wedge-form teeth, cohering at the tips; inner, a membrane divided into sixteen flat teeth; veil square. There are three species.

FUNCHAL, or **FUNCHIAL**, the capital of Madeira, a large, strong, handsome, and populous town, with two castles, and several fine churches. Lon. 16. 49. W. Lat. 32. 32. N.

FUNCTION, in algebra, denotes any compound quantity; and when one of the component quantities is variable, it is said to be a variable function. Functions are formed either by addition, subtraction, multiplication, division, involution, or evolution; as also by the resolution of equations. But besides these, which are called algebraical functions, there are others called transcendental, arising from the management of exponents, logarithms, &c. For a farther account of functions, the reader may consult Bernoulli, *Oper. T. 3*, also Euler's *Analys. Infinitor*.

FUNCTION, in the animal œconomy, is by physicians divided into vital, animal, and natural.

1. **FUNCTIONS, ANIMAL**, include the senses, memory, judgment, and voluntary motions; without any or all of which an animal may live, but not very comfortably. The animal functions perform the motion of the body by the action of the muscles; and this action consists chiefly in the shortening the fleshy fibres, which is called contraction, the principal agents of which are the arteries and nerves distributed in the fleshy fibres. All parts of the body have their own functions, or actions, peculiar to themselves. Life consists in the exercise of these functions, and health in the free and ready exercise of them.

2. **FUNCTIONS, NATURAL**, are such as it cannot subsist any considerable time without; as the digestion of the aliment, and its conversion into blood.

3. **FUNCTIONS, VITAL**, are those necessary to life, and without which the individual cannot subsist; as the motion of the heart, lungs, &c.

FUNDS, PUBLIC, the taxes or other public revenues appropriated to the payment of the interest or principal of the national debt. When the practice was first adopted of borrowing money of individuals for defraying the extraordinary expences of the state, the produce of some particular tax was generally appropriated as the fund out of which the principal and interest of the debt was to be discharged. The possession of the acknowledgement given by government for the money advanced, establishing a right to receive the payments from the fund originally agreed upon, the sale of these securities was considered as a sale of the claim upon the fund; and as the acknowledgements given were of different kinds, the general appellation of the provision on which they rested was found more convenient for purposes of business: thus the sale and purchase of the government securities was commonly called the sale or purchase of the public funds, till at length the expression has so far varied from its original signification, that instead of meaning the revenue out of which public debts or the interest of them is payable, it denominates the capital of such debts, in which sense it is generally used. Hence the term is now used to signify those large sums which have been lent to government, and constitute the national debt; and for which the lenders, or their assignees, receive interest from revenues allotted for that purpose. The term stock is used in the same sense, and is also applied to the sums which form the capital of the bank of England, the East India and South Sea companies; the proprietors of which are entitled to a share of the profits of the respective companies. The practice of funding was introduced by the Venetians and Genoese in the sixteenth century, and has been adopted since by most of the nations in Europe. Princes had often borrowed money, in former times, to supply their exigencies, and sometimes mortgaged their territories in security: but these loans were generally extorted, and their payment was always precarious; for it depended on the good faith and success of the borrower, and never became a regular burden on posterity. The origin of funds is derived from the peculiar manners and circumstances of modern Europe. Since the invention of gunpowder, and the progress of commerce, the military occupation has become a distinct employment in the hands of mercenaries; the apparatus of war is attended with more expence; and the decision of national quarrels has often been determined by command of money rather than by national bravery. Ambitious princes have therefore borrowed money, to carry on their projects with more vigour. Weaker states have been compelled, in self-defence, to apply to the same resource; the wealth introduced by commerce has afforded the means; the regularity of administration, established in consequence of the progress of civilization, has increased the confidence of individuals in the public security; the complicated system of modern policy has extended the scenes of war, and prolonged their duration; and the colonies established by the mercantile nations have rendered them vulnerable in more points, and increased the expence of defending them. When a greater sum has been required for the annual expence, than could easily be supplied by annual taxes, the government have proposed terms, to their own subjects, or foreigners, for obtaining an advance of money, by mortgaging the revenue of future years for their indemnification. This mortgage may either be for a limited period, or perpetual. If the sum allotted annually for the benefit of those who advance the money, be considerably greater than the interests of the sums advanced, they may agree to accept of such allowance, for a limited time, as a full equivalent. Thus, they may either agree for the casual produce of the revenue assigned; or a fixed annuity for a greater or less number of years; or a life-annuity to themselves or nominees; or an annuity for two or more lives; or an annuity, with the benefit of survivorship, called a tontine, in which scheme, the whole sum to which the original annuitants were entitled continues to be distributed among the survivors. The establishment of the funds was introduced in Britain at the Revolution; and has since been gradually enlarged, and carried to an amazing extent. The various methods above-mentioned have been used in their turns, but perpetual annuities have been granted for the greatest part: and, even when the money was originally advanced on other conditions, the lenders have been sometimes induced,

induced, by subsequent offers, to accept of perpetual annuities, instead of the former terms. The debt, for which perpetual annuities are granted, is called the redeemable debt, and the other is called the irredeemable debt. Although the debts thus contracted by government are seldom paid for a long term of years; yet any creditor of the public may obtain money for what is due to him when he pleases, by transferring his property in the funds to another; and regular methods are appointed for transacting these transfers in an easy manner. By these means, the stocks become a kind of circulating capital; and have the same effect, in some respects, as the circulating money in the nation. When a stockholder transfers his share, he may sometimes be able to obtain a greater price than the original value, and at other times be obliged to accept of a less one. The value of the funds depends on the proportion between the interest they bear, and the benefit which may be obtained by applying the money to other purposes. It is influenced by the plenty or scarcity of money, and by the greatness or smallness of the public debt; and it is impaired by any event which threatens the safety, or weakens the credit, of the government. The business of stock-jobbing is founded on the variation of the prices of stock. Persons possessed of real property may buy or sell stock, according to their notion that the value is likely to rise or fall, in expectation of making profit by the difference of price. And a practice has taken place among persons who often possess no property in the funds, to contract for the sale of stock against a future day, at a price now agreed on. For instance: A agrees to sell B 1000*l.* of bank-stock, to be transferred, in twenty days, for 1200*l.* A has, in fact, no such stock; but, if the price of bank-stock, on the day appointed for the transfer, should be only 118 per cent, A may purchase as much as will enable him to fulfil his bargain for 1180*l.* and thus he gains 20*l.* by the transaction; on the contrary, if the price of bank-stock be 125 per cent, he will lose 50*l.* The business is generally settled without any actual purchase or transfer of stock, by A paying to B, or receiving from him, the difference between the current price of the stock, on the day appointed, and the price bargained for. This practice, which is really nothing but a wager concerning the price of stock, is contrary to law; yet it is carried on to a great extent. In the language of Exchange-alley, where matters of this kind are transacted, the buyer is called a bull, and the seller a bear. As neither party can be compelled by law to implement these bargains, their sense of honour, and the disgrace and loss of future credit, which attend a breach of contract, are the principles by which the business is supported. When a person declines to pay his loss, he is called a lame duck, and dare never afterwards appear in the alley. This opprobrious appellation, however, is not bestowed on those whose failure is owing to want of ability, providing they make the same surrender of their property voluntarily, which the law would have exacted if the debt had been entitled to its sanction. The interest or dividend on the stock is paid half-yearly; and the purchaser has the benefit of the interest due on the stock he buys, from the last term to the time of purchase. The principal funds established at different periods are, the Aggregate Fund, the South Sea Fund, the General Fund, the Sinking Fund, and the Consolidated Fund. The Aggregate Fund was established in the year 1715, and had this name given to it, because it consisted of a great variety of taxes and surpluses of taxes, which were in that year consolidated, and given as the security for discharging the interest and principal of all the Exchequer bills then outstanding, and of some other public debts; and likewise for the payment of 120,000*l.* per annum to the civil list. The South Sea Fund was established in 1716, and was so called because appropriated to pay the interest and allowance for management on the capital of the South Sea Company. The General Fund was also established in 1716, by making perpetual various duties which had been granted for the term of thirty-two years, and consolidating them with some other duties into one fund. It was appropriated chiefly to the payment of the interest on various sums raised by lotteries during the reign of Queen Anne. The Sinking Fund consisted of the surpluses of the three funds just-mentioned, whenever the produce of the taxes composing them should be greater than the charges upon them. The establishment of these funds formed part of a plan for a general reduction of the interest payable on the public debts, and this being effected, the charge on each of the three funds was of course lessened con-

siderably, and the future overplus was directed to be carried into a fourth fund, to which was given the name of the Sinking Fund, because appropriated to the purpose of redeeming or sinking the public debts. The act of parliament by which this fund was established, expressly ordained that it should be applied to the discharge of the public debts, and "to or for none other use, intent, or purpose whatsoever;" yet in the course of a few years many encroachments were made upon it, and ultimately it became a mere nominal distinction, the whole produce of it being usually taken towards the supplies of the current year. The Consolidated Fund was established in consequence of a new arrangement of the public accounts in the year 1786, when the funds above-mentioned were abolished, and the whole of the public revenue, (except the annual grants) included under this general head. Out of this fund are paid the interest and expences of management of all the public debts, the interest on Exchequer bills, the civil list, pensions to the royal family and others, salaries and allowances to various public officers, and some miscellaneous annual expences. The surplus of the produce of the fund, after satisfying all these charges, is annually granted by parliament as part of the ways and means for raising the supplies voted. The debts bearing a certain rate of interest payable till the principal shall be redeemed, are denominated, in the language of finance, perpetual annuities, or redeemable annuities; but, in the common course of business, they are called funds or stocks: a small part of the public debts consist of annuities for a certain term of years, commonly called long or short annuities: there are also some life and tontine annuities still existing; but the whole of the terminable annuities bears a very small proportion to the permanent debts. The perpetual annuities are distinguished according to the rate of interest they pay, or the time or purpose of their creation; and when by a new loan government contracts an additional debt, bearing a certain fixed interest, the capital thus created is added to the amount of that part of the public debt which bears the same rate of interest, and the produce of the taxes imposed for payment of the interest of such new debt being carried to the fund established for paying the interest of the former capital, the old and new debts are consolidated, and the whole interest made payable out of the general produce of the fund; hence we have three or four per cent. consolidated annuities, according to the rate of interest payable on the capital. The interest on all the public debts was formerly paid at the Exchequer; but the bank being found a much more convenient place for this purpose, nearly the whole is now payable there, the company receiving a certain allowance from government for managing all business relative to the public funds. The different denominations of the funds transferable at the Bank of England, with the days on which the transfers are made, and the times when the interest or dividend becomes due, are at present as follows:

Funds.	Transfer days	Divid. due.
Consolid. 3 per C. An....	Tues. Wed. Th. and Fr.	Jan. 5, and July 5.
Three per C. An. 1726....	Tues. and Thurs.....	
Navy 5 per C. An.....	Mon. Wed. and Fr.....	
Bank Stock.....	Tues. Th. and Fr.....	April 5, and Oct. 10.
5 per C. An. 1797, 1802....	Tues. Th. and Fr.....	
4 per C. Consolid. An....	Tues. Th. and Sat.....	
Reduced 3 per C. An....	Tues. Wed. Th. and Fr.	May 1, and Nov. 1.
Long Annuities.....	Mon. Wed. and Sat.....	
Imperial 3 per C. An....	Mon. Wed. and Fr.....	
Imperial An. 25 years....	Tues. Th. and Sat.....	March 25, and Sept. 25.
Irish 5 per C. An.....	Tues. Th. and Sat.....	
Irish Terminable An....	Tues. Th. and Sat.....	

Transferable at the South Sea House.

South Sea Stock.....	Mon. Wed. and Fr....	Jan. 5, and July 5.
New South Sea An.....	Tues Th. and Sat.....	
Three per Cent. An.....	Tues. and Thurs.....	Jan. 5, and July 5.
Old South Sea An.....	Mon. Wed. and Fr....	

As the prices of the several funds are continually fluctuating, and there is frequently a considerable difference in the interest produced by investing money in different funds, the following table of the prices which each fund should be at to produce an equal

equal interest, will be found very useful to persons investing their money in these securities.

TABLE,

Shewing the comparative Value per Cent. of the several Public Funds, and the Annual Interest produced by 100l. invested at different Prices.

3 per Cent.	4 per Cent.	5 per Cent.	Bank-Stock, 7 per c.	Ind. St. 10½ per Cent.	Annual Interest.

Tables of all the intermediate prices, and for comparing the value of the terminable annuities with the other funds are given in Fairman's Guide to Purchasers in the Public Funds. Some useful information respecting the funds, and the mode of transacting business at the bank and stock exchange, will also be found in Mortimer's "Every Man his Own Broker."

FUNDAMENT, in anatomy, the lowest part of the intestinum rectum, called by anatomists the anus. See **ANATOMY**.

FUNDAMENTAL NOTE, in music, the principal note in a song, or composition, to which all the rest are in some measure adapted, and by which they are swayed: it is otherwise called the key to the song.

FUNDI, in ancient geography, a town of Latium, on the Via Appia, near Cajeta; now called Fundi.

FUNDY, a bay of North America, between New England and Nova Scotia, remarkable for its tides, which rise to the height of fifty or sixty feet, and flow so rapidly as to overtake animals which feed upon the shore. It has a good fishery.

FUNEN, **FIONIA**, or **FYEN**, a considerable island of Denmark, in the Baltic sea, separated from Jutland by a strait called the Lesser Belt, and from the island of Zealand by the Great Belt. It is 340 miles in circuit; is fertile in wheat and barley, and

abounds in grain, cattle, horses, game, and fish. Odensee is the capital. Lon. from 9. 40. to 10. 50. E. Lat. 55. 7. to 55. 42. N.

FUNERAL RITES, ceremonies accompanying the interment or burial of any person. See **BURIAL**. These rites differed among the ancients, according to the different genius and religion of each country. The Egyptians, among the rest of their funeral rites, embalmed their dead. Among the ancient Greeks it was usual sometimes, before the interment, to put a piece of money into the mouth of the deceased, which was thought to be Charon's fare for wafting the departed soul over the infernal river. This ceremony was not used in those countries which were supposed to be situated in the neighbourhood of the infernal regions, and to lead thither by a ready and direct road. The corpse was likewise furnished with a cake composed of flour, honey, &c. which was designed to oppose the fury of Cerberus, the door-keeper of hell, and to procure the ghost a safe and quiet entrance. During the time the corpse continued in the house, there stood before the door a vessel of water, the design of which was, that those concerned about the body might purify themselves by washing; it being the opinion of the Greeks as well as of the Jews, that pollution was contracted by touching a dead body. The ceremonies by which they expressed their sorrow for the death of their friends were various; but it seems to have been a constant rule to recede as much as possible in habit and behaviour from their ordinary customs. For this reason they abstained from banquets and entertainments; they divested themselves of all ornaments; they tore, cut off, or shaved their hair, which they cast into the funeral-pile, to be consumed with the body of their deceased friend. Sometimes they threw themselves on the ground, and rolled in the dust, or covered their head with ashes; they beat their breasts, and even tore their flesh with their nails upon the loss of a person they much lamented. When persons of rank, such as public magistrates, or great generals, died, the whole city put on a face of mourning: all public meetings were intermitted; the schools, baths, shops, temples, and all places of concourse, were shut up. Interring or laying the dead in the ground, seems to have been the most ancient practice among the Greeks; though burning came afterwards to be generally used among them. It was customary to throw into the funeral-pile those garments the deceased usually wore. The pile was lighted by one of the dead person's nearest relations or friends, who made prayers and vows to the winds to assist the flames, that the body might quickly be reduced to ashes; and during the time the pile was burning, the dead person's friends stood by it, pouring libations of wine, and calling upon the deceased. When Numa reformed the religion of Rome, he ordered that the pontiffs should have the care of the funeral ceremonies; which, in most respects, were like those of the Greeks already described. The funeral-rites among the Hebrews, were solemn and magnificent: when any person was dead, his relations and friends rent their clothes; which custom is but faintly imitated by the modern Jews, who only cut off a bit of their garment, in token of affliction. It was usual to bend the dead person's thumb into the hand, and fasten it in that posture with a string; because the thumb then having the figure of the name of God, they thought the devil would not dare to approach it. When they came to the burying-place, they made a speech to the dead in the following terms: "Blessed be God, who has formed thee, fed thee, maintained thee, and taken away thy life. O dead! he knows your numbers, and shall one day restore your life, &c." Then they spoke the eulogium, or funeral-oration, of the deceased; after which they said a prayer, called the righteousness of judgment; then turning the face of the deceased towards heaven, they called out, "Go in peace." The ancient Christians testified their abhorrence of the Pagan custom of burning the dead; and always deposited the body entire in the ground: and it was usual to bestow the honour of embalming upon the martyrs, at least, if not upon others. They prepared the body for burial, by washing it with water, and dressing it in a funeral-attire. The exportation, or carrying forth of the body, was performed by near relations, or persons of such dignity as the circumstances of the deceased required. Psalmody, or singing of psalms, was the great ceremony used in all funeral-processions among the ancient Christians. In the Latin church, when a person is dead, they wash the body, and put a crucifix in its hand. At its feet stands a vessel full of holy water, and a sprinkler, that they who come in may sprinkle both themselves and the deceased. In the mean time some priest stands by the corpse, and prays for the

the deceased till it is laid in the earth. In the funeral-procession, the exorcist walks first, carrying the holy water; next the cross-bearer, afterwards the rest of the clergy, and last of all the officiating priest. They all sing the miserere, and some other psalms; and at the end of each psalm a requiem. We learn from Ale's ritual, that the faces of deceased laymen must be turned towards the altar, when they are placed in the church; and those of the clergy, towards the people. The corpse is placed in the church surrounded with lighted tapers: after the office for the dead, mass is said; then the officiating priest sprinkles the corpse thrice with holy water, and as often throws incense on it. The body being laid in the grave, the friends and relations of the deceased sprinkle the grave with holy water.

FUNERAL EXPENCES, in law, are allowed previous to all other debts and charges; but if the executor or administrator be extravagant, it is a species of devastation or waste of the substance of the deceased, and shall only be prejudicial to himself, and not to the creditors or legatees of the deceased. But, in strictness, no funeral-expences are allowable against a creditor, except for the shrouds, coffin, ringing the bell, parson, clerk, grave-digger, and bearer's fees, but not for pall or ornaments.

FUNGI, [from *αμύγος*, *fungus*.] in botany, the fourth order of the twenty-fourth class of vegetables, in the Linnaean system; comprehending all those which are of the mushroom kind, and which in Tournefort's constitute the second, third, fourth, fifth, sixth, seventh, and eighth, genera of the first section in the class seventeen. This order contains ten genera. See **AGARICUS**, **BOLLETUS**, **CLAVARIA**, **LYCOPERDON**, &c. and **BOTANY**.

FUNGI, an order of plants in the *Fragmenta Methodi Naturalis* of Linnaeus.

FUNGITÆ, in natural history, a kind of fossile coral, of a conic figure, though sometimes flattened and striated longitudinally.

FUR, or **FURR**, in commerce, signifies the skins of wild beasts, dressed in alum with the hair on; and used as a part of dress, by princes, magistrates, and others. The kinds most in use are those of the ermine, sable, castor, hair, coney, &c. See **CASTOR**, **CAVIA**, **LEPUS**, **MUSTELA**, &c. It was not till the later ages that the furs of beasts became an article of luxury. The refined nations of antiquity never made use of them; those alone who were stigmatized as barbarians were clothed in the skins of animals. Those at present used are imported chiefly from North America, and Russia.

FURCA, in antiquity, a piece of timber resembling a fork, used by the Romans as an instrument of punishment.

FURCHE, in heraldry, a cross forked at the ends.

FURIA, in natural history, a genus of the class and order *vermes intestina*, having a body linear, equal, filiform, and ciliate, each side with a single row of reflected prickles, pressed close to the body; one species only is mentioned by Gmelin, viz. the *F. infernalis*, which inhabits the vast marshy plains of Bothnia and Finland, where it crawls up shrubs and sedge-grass, and being carried forwards by the wind, penetrates suddenly into the exposed parts of men and cattle, where it quickly buries itself under the skin, leaving a black point where it had entered, which is frequently succeeded by excruciating pains, inflammation, and even death. This fatal termination takes no length of time, a few hours, or a day, being sufficient for the whole process, unless the animal be almost instantly extracted by means of the knife, or a milk-poultrice.

FURIE, or **FURIES**, in Pagan mythology, goddesses, whose offices it was to punish the guilty after death. They sprang from the blood of the wound which Cælus received from his son Saturn. According to others, they were daughters of Earth, and conceived from the blood of Saturn. Some make them daughters of Acheron and Night, or Pluto and Proserpine. According to the more received opinions, they were three in number, Tisiphone, Megera, and Alecto, to which some add Nemesis. Plutarch mentions only one called Adrasta, daughter of Jupiter and Necessity. They were supposed to be the ministers of the vengeance of the gods; stern and inexorable; always employed in punishing the guilty upon earth, as well as in the infernal regions. They were also called Eumenides and Erinnydes. The Athenians styled them *εὐμενίδες*, venerable goddesses. Their worship was almost universal; and people dared not to mention their names, or fix their eyes upon their temples.

VOL. II.—NO. 90.

FURLING, in the sea-language, signifies the wrapping up and binding any sail close to the yard; which is done by hawling upon the clew-lines, bunt-lines, &c. which wraps the sail close together, and being bound fast to the yard the sail is furled.

FURLONG, [*farlang*, Sax.] a long measure, equal to one-eighth of a mile, or forty poles. It is also used, in some law-books, for the eighth part of an acre.

FURLOUGH, in the military language, a licence granted by an officer to a soldier, to be absent for some time from his duty.

FURNACE, an utensil to raise and maintain a vehement fire in, whether of coal or wood. In order to apply fire, to manage and to direct it where it is to act, furnaces are convenient, and they are the most necessary and indispensable instruments to chemists. The materials of which they are constructed ought to be sufficiently proof against that degree of heat, which they are intended to be exposed to. Commonly they are built of bricks, made of sand and clay, or of cast-iron, or of iron plates, which, the better to be defended against the fire, are coated (in the inside) to the thickness of an inch with Windsor loam. According to Lewis, various kinds of fire-proof furnaces, for small experiments, may be prepared from black-lead crucibles. The burning of the fuel is kept up in the furnace either by a natural current of air, which is caused by the fire itself, and such a furnace is called an air wind-furnace; or it is done by compressed air, conveyed to the furnace by a large bellows, as in blast-furnaces. In all furnaces the principal things to be attended to are, 1. To confine the heat as much as possible to the matter to be operated upon; 2. To prevent its being dissipated; 3. To produce as much heat with as little fuel as possible; and, 4. To have it in our power to regulate the degree of heat according to our pleasure. To answer the first intention, the fire is usually confined in a chamber or cavity built on purpose for it, and furnished with a door for putting in the fuel; a grate for supporting it, and allowing air to pass through, as well as the ashes to drop down into a cavity provided on purpose, and called the ash-pit. Thus the heat produced by the inflamed fuel is confined by the sides of the furnace, and obliged to spend great part of its force upon the subject inclosed. The second intention, viz. to prevent the dissipation of the heat, is obtained by shutting the door of the furnace; taking care that the chimney be not too wide, and that the matter to be acted upon be placed in such a manner, that the fire may have its full effect upon it as it goes up the chimney. The third intention, which is the most important, is at the same time the most difficult to answer, and depends entirely upon the proportion between the spaces betwixt the furnace-bars and the wideness and height of the chimney. This will appear from a consideration of the principles on which the degrees of inflammation are produced. These depend entirely on the current of air which passes through the inflamed fuel. As soon as the fuel is set on fire, a certain degree of heat is produced; but unless a constant influx of air is admitted through the burning fuel, the fire is instantly extinguished; nor is it possible by any means to renew the inflammation until we admit a stream of fresh air among the fuel. When this is done, a rarefaction commences in the air of the fire-place of the furnace: so that it is no longer a counterpoise to the external air, and is therefore driven up the chimney by that which enters at the ash-pit. This again passing through the fuel, is rarefied in its turn; and giving place to fresh quantities, there is a constant flow of air up the chimney. In proportion to the rarefaction of the air in the fire-place, the greater is the heat. But by a certain construction of the furnace, the under part of the chimney will become almost as strongly heated as the fire-place; by which means, though a very strong current of air is forced through the fuel, yet as great part of the heat is spent on the chimney, where it can be of no use, the fuel is wasted in a very considerable degree. To avoid this, we have no other method than to contract the throat of the chimney occasionally by a sliding-plate; which when put quite in, shuts up the whole vent; and by being drawn out more or less, leaves a larger or smaller vent at pleasure. This plate ought to be quite drawn out till the fuel is thoroughly kindled, and the furnace well heated, so that a current of air may flow strongly through the fuel. After this the plate is to be put in a certain length, so as just to prevent the smoke from coming out at the door of the furnace. The rarefaction of the air in the fire-place will solicit a very considerable draught of air, which will keep the fuel

6.Q

fuel

fuel inflamed to a great degree; at the same time that the heat, being reflected from every part of the furnace excepting that narrow passage where the smoke goes up, becomes very intense. A large quantity of fuel may be put in at once, which will consume slowly, and thus require but little attention in comparison with those furnaces where no such precaution is used. The sliding-plate may be made of cast iron in those furnaces where no great heat is excited; but in others fire-clay would be more convenient. The contrivance, however, is scarce applicable to those furnaces where great quantities of metal are to be melted; and accordingly the waste of fuel there is immense. It is computed, that the iron works of Carron in Stirlingshire consume annually as many coals as would be sufficient for a city containing 790,000 inhabitants. The fourth intention, viz. that of regulating the heat, is accomplished by allowing only a certain quantity of air to pass through the fuel. For this purpose, says Dr. Black, it is necessary to have the command of the furnace below; the parts above being frequently filled with small quantities of soot. The best method of managing this is to shut up the door of the ash-hole perfectly close, and to have a set of round holes bearing a certain proportion to one another; and their areas being as 1, 2, 4, 8, 16, &c. Seven or eight of these ought to be made in the door of the ash-pit, which will give a sufficient command over the fire. When the fire is to be increased to the utmost, all the passages both above and below are to be thrown open, and the height of the vent augmented; which, by increasing the height of the column of rarefied air, increases also the motion of that through the fuel, and of consequence also the heat of the furnace. Macquer recommends another tube applied to the ash-pit, widest at the end farthest from the furnace, and tapering gradually towards it. The intention of this is to augment the current and velocity of the air, by its being made to pass from a wider into a narrower vent; but though this is no doubt true, the air will not ultimately move with greater velocity than if the tube were not there. It can only be useful therefore in cases where the furnace is placed in a small room, and the tube itself has a communication with the external air.

FURNACE, CUPELLING, or FURNACE, ESSAYING, described in Cramer's Art of Essayng. See Plate LXXVII. fig. 1. Make with iron plates a hollow quadrangular prism, 11 inches broad and nine inches high, *aa bb*, ending at top in a hollow quadrangular pyramid, *bb cc*, seven inches high, terminating in an aperture at top seven inches square. This prism must be closed at bottom with another iron plate, which serves as a basis or bottom to it, *aa*. 2. Near the bottom make a door, *e*, three inches high, and five inches broad, that leads to the ash-hole. 3. Above this door, and at the height of six inches from the basis, make another door, *f*, of the figure of a segment of a circle, four inches broad at its basis, and 3½ inches high in the middle. 4. Then fasten three iron plates on the fore-part of this furnace. Let the first of them, *gg*, 11 inches long, and half an inch high, be fastened, so that its lower edge shall rest against the bottom of the furnace, with three or four rivets: and in such a manner, that there may be between the upper edge of the said plate and the side of the furnace a groove so wide, as that the sliders of the lower door, *kk*, may be put into it, and freely move backwards and forwards therein; these must be made of a thicker iron plate. The second iron plate, *hh*, 11 inches long, three inches high, and perfectly parallel to the foregoing plate, must be fastened in the space between the two doors, in such manner, that both the upper and the lower edges of it may form a hollow groove with the side of the furnace. One of these grooves, which is turned downwards, serves to receive the upper edge of the sliders that shut the lower door, No. 2. The other, that turns upwards, is to receive the inferior edges of the sliders of the small door above, No. 3. The third plate, *ii*, which is like the first, must be riveted close above the upper door, in such manner that it may form a groove turning downwards, and contiguous to the upper edge of the upper door, No. 3. 5. To shut both doors, No. 2 and 3, adapt to each of them two sliders made of iron plates, that they may move within the above-mentioned grooves, *kk ll*. But the two sliders belonging to the upper door, No. 3, must have each a hole near the top; that is, one a small hole one-fifth part of an inch broad, and one inch and a half long, *m*; and the other a semicircular aperture, one inch high and two inches broad, *n*. Let, besides, each slider have a handle, that they may be laid hold of when they are to be removed. 6. Moreover,

let five round holes, one inch broad, be bored in the furnace; two of which must be made in the fore-part of the furnace, *oo*, two others in the back part; all at the height of five inches from the bottom, but 3½ inches distant from each side of the furnace; and, finally, a fifth hole, *p*, at the height of one inch above the upper edge of the upper door, *f*. 7. In short, let the inside of the furnace be armed with iron hooks, jutting out half an inch, and about three inches distant from each other, to fasten the lute with which the furnace is to be covered over within. 8. Let then an iron, moveable, hollow, quadrangular pyramid, *q*, three inches high, be adapted to the upper aperture, *d*, of the furnace, at the basis seven inches broad, ending upwards in a hollow tube, *r*, three inches in diameter, two inches high, almost cylindrical, though somewhat convergent at top. This prominent tube serves to support a funnel or flue, which is almost cylindrical, hollow, made of iron plates, and two feet high; and which, when a very strong fire is required, is put perpendicularly upon the shorter tube, in such a manner, that it enters close into it, one and a half or two inches deep, and may again be taken off at pleasure, when there is no need of so strong a fire. This pyramidal cover, *q*, must have two handles, *ss*, adapted to it, that it may be laid hold of, and thus be taken off or put on again: and that this, being put on the aperture, *d*, of the furnace, may not be easily thrown down, let an iron plate be riveted to the right and left upper edge of the furnace, *cc*, and be turned down towards the inside, so as to make a furrow open before and behind, into which the lateral edges of the cover may enter and be fastened, and at pleasure be moved backwards and forwards, whenever it must be put on or moved. 9. Let a square ledge, made of a thick iron plate, be fastened at the top of the upper edge of the lower door, *e*, to support the grate and the lute; but it must be made of two pieces, that it may be easily introduced into the cavity of the furnace. This assay-oven must afterwards be covered over on the inside with lute, as follows:—That the fire may be better confined, and that the iron may not be destroyed by growing red hot, the whole inside of the furnace must be covered over with lute, one finger or one finger and a half thick. The lute fit for this is described under Chemistry. But before using this lute, first put within the furnace small iron bars, equal in length to the diameter of the oven, quadrangular, prismatical, half an inch thick, having their extremities supported by a square iron ledge, and three-fourths of an inch distant from each other; and fasten them so, that their flat sides may be oblique with regard to the transverse section of the furnace, and that the two opposite angles may look one upwards and the other downwards: the bars must not be laid flat, but edgewise; by which situation the ashes of the fuel are prevented from being detained too long between the interstices of the iron bars, and from making an obstruction that would oppose the free draught of the air. The furnace being then covered over with lute, and dried up by a gentle heat, is at last fit for docimastical operations, and especially for such as must be performed in the assay-oven. When an operation is to be made in this furnace, let through the four lower holes above described, *oo*, before and behind, and directly opposite to each other, two iron bars one inch thick, and long enough that their extremities on every side may jut a little out of the holes. These serve to support the muffle and its bottom. Then introduce the muffle through the upper aperture of the furnace, *d*, and place it upon the above described iron bars, in such a manner that the open fore-side of it may be contiguous to the inward border of the upper door, *f*. The fuel is introduced through the top of the furnace, *d*; the cover of which, *q*, on this account, must be moveable, and not very heavy. The best fuel is charcoal made of the hardest wood, especially of beech, broken into small pieces of the bigness of an inch, wherewith the muffle must be covered over some inches high. Large pieces would not answer, because they could not fall through the narrow interstices, between the sides of the muffle and those of the furnace, and of course could not sufficiently surround the circumference of the muffle; so that there would be on every side places void of fuel, and the fire would be either not strong enough or unequal. But if, on the contrary, coals too small were used, then a great part would fall immediately through the interstices of the grate into the ash-hole; the smallest parts of them would turn too soon into ashes, and by increasing the heap of ashes, obstruct the free draught of the air, which is here very requisite. A perfect management of the fire is necessary in performing operations

rations in this furnace; therefore the chemical reader must give attention to what follows. If the door of the ash-hole, *e*, is quite open; and the sliders of the upper door, *f*, drawn towards each other, so as to touch one another in the middle of the door; and if, besides, the cover, *g*, and the funnel adapted to its tube, *r*, are upon the top, *d*, of the furnace; the fire will be then in the highest degree possible; though, in the mean time, it is hardly ever necessary to put the funnel on, except in a very cold season: but if, after having disposed the furnace in the manner just described, red burning coals are put into the open upper door, *f*, of it, the fire is still more increased thereby: however, this is very seldom or never necessary. When the upper door is shut with only that slider that has a narrow oblong hole in it, *m*, then the heat becomes a little less; but it diminishes still more when shut with the other slider, that has it in a semicircular hole, *n*, which is larger than that of the first slider: nay, the heat again is less when the funnel put at the top of the cover is taken away. Finally, the door of the ash-hole being either in part or totally shut, the heat is still diminished; because the draught of air so necessary to excite the fire is thereby hindered: but if, besides all these, the upper door be opened wide, then the cold air rushing into the muffle, cools the bodies put under it, that are to be changed, to a degree incompatible with any operation, as it will entirely hinder the boiling of the lead. If, during the operation, the fire begins to decay, or to grow unequal, it is a sign that there are places void of coals between the sides of the furnace and those of the muffle; therefore, in this case, the coals must be stirred on every side with an iron rod, introduced through the upper hole, *p*, of the furnace, that they may fall together, and thus act equally and in a proper manner. However, the effect does not always uniformly answer, even when the apparatus has been made with all the exactness mentioned. The cause of this difference has most commonly its origin in the various dispositions of the air: for as every fire is more excited, in proportion as the air, more condensed, and more quickly agitated, strikes the fuel more violently (which the effect of the bellows plainly shews;) it thence appears, that in warm and wet weather, when the atmosphere is light, the fire must be less efficacious in furnaces, that likewise, when several furnaces, situated near each other, are burning at the same time, the fire is in part suffocated, because the circum-ambient air is thereby rendered more rare and lighter. The same effect is produced by the sun, especially in summer, when it shines upon the place where the furnace is situated. The atmosphere, on the contrary, being heavier in cold dry weather, excites a very great fire. The heat of the fire acts the stronger upon the bodies to be changed, as the muffle put in the furnace is less; as it has more and larger segments cut out of it; as its sides are thinner; in short, as there are more vessels placed in the hinder part of it; or the contrary. In this case, when many of the conditions requisite for the exciting of fire are wanting, the artificer, with all his skill, will hardly be able to excite the fire to a sufficient degree, to perform operations well, in common assay-ovens, even though he uses bellows, and puts coals into the upper door of the furnace. For this reason, the grate ought to be put almost three inches below the muffle, lest the air, rushing through the ash-hole, should cool the bottom of the muffle, which happens in common assay-ovens; and again, that the smaller coals, almost already consumed, and the ashes, may more easily fall through the interstices of the grate, and the larger coals still fit to keep up the fire be retained. Lastly, the above-mentioned funnel is added, that the blowing of the fire being, by means of it, increased as much as possible, this may at last be carried to the requisite degree; for the fire may always be diminished at pleasure, but cannot always be increased, without the assistance of a proper apparatus.

FURNACE, MR. WATT'S STEAM-ENGINE. The steam-engine furnace is described in the specification of the patent obtained for the invention by Mr. Watt of Birmingham. His "improved methods of constructing furnaces, or fire-places, consist in causing the smoke or flame of the fresh fuel, in its way to the flues or chimney, to pass, together with a current of fresh air, through, over, or among, fuel which has already ceased to smoke, or which is converted into coaks, charcoal, or cinders, and which is intensely hot; by which means the smoke and grosser parts of the flame, by coming into close contact with, or by being brought near unto, the said intensely hot fuel, and being mixed with the current of fresh or unburnt air, are consumed, or converted into heat, or into pure flame free from smoke." This is done, "first, by stopping up

every avenue or passage to the chimney or flues," except such as are left in the interstices of the fuel, by placing the fresh fuel above, or nearer to the external air, than that which is already converted into coaks or charcoal; and by constructing the fire-places in such a manner that the flame, and the air which animates the fire, must pass downwards, or laterally, or horizontally, through the burning fuel, and pass from the lower part, or internal end or side, of the fire-place, to the flues or chimney. In some cases, after the flame has passed through the burning fuel, it is made to pass through a very hot funnel, flue, or oven, before it comes to the bottom of the boiler, or to the part of the furnace where it is proposed to melt metals or perform other offices, by which means the smoke is still more effectually consumed. In other cases, the flame is carried immediately from the fire-place into the space under a boiler, or into the bed of a melting or other furnace. Fig. 2, Plate LXXVII. shews a section of a fire-engine boiler, and its furnace, which has been chosen for an example of the application of this new method to the heating and evaporating of water. A A is the boiler, which may be made of any form suitable to its use. B B is a flue, surrounding the boiler as usual. C is the uptake, or passage from the space under the boiler to the flues. D D is a funnel or flue for the flame to come from the fire-place to the boiler. E E is a place to contain the ashes; and F is a door to take them out at, which must be kept continually shut during the time of working. G H is the fire-place: the fresh fuel is put in at G, and gradually comes down as the fuel below consumes. The part at H is very hot, being filled with the coaks or coals which have ceased to smoke. I is an opening or openings, to admit fresh air, and regulate the fire. K is a door into the space under the boiler; and which being opened, admits air, and stops the draught of the chimney when the operation is wanted to cease. Fig. 3 is a section of the same fire-place in the other direction; in which M M is the back of the fire-place; L the brick arch on which the fuel lies; and E the ash-hole. Fig. 4 is an outside view of the same fire-place, shewing the air-holes I I, and the ash-hole door E; and fig. 5, is a plan of the same, with part of the boiler seated; taken in the line Z of fig. 2. The dotted lines represent the flues, and the darts point out the direction of the flame. The fire is first kindled upon the brick arch L, fig. 2; and when well-lighted, more fuel is gradually added until it is filled up to G. Care is taken to leave proper interstices for the air to pass, either among the fuel, or between the fuel and the front-wall N; and as much air is admitted at I I, as can be done without causing the smoke to ascend perpendicularly, which it will always do if too much air is admitted at I I. The dimensions of this fire-place are shewn by the scale, and are properly adjusted for burning about 84lb. of coals in an hour; where greater or less quantities are required to be burnt, the furnace must be enlarged or diminished; or, if much greater, more furnaces than one must be employed. Fig. 6. represents this new fire-place as applied to a furnace for melting iron and other metals, and constructed without the funnel, or perpendicular flue D in fig. 2. The same letters refer to the same parts in all these figures. Mr. Watt also constructs these new fire-places so that the part G H lies sloping, or horizontal, and otherwise varies the figure or form, and proportions; but in all cases the principle is the same; the fresh or raw fuel being placed next the external air, and so that the smoke or flame passes over or through the cooked or charred part of the fuel. He also occasionally covers the opening G, and causes the air to enter only, or principally, at I I. In particular cases, he places the fresh fuel on a grate as usual, as at A fig. 7, and beyond that grate, or near at the place where the flame passes into the flues or chimneys, he places another smaller grate B, on which he maintains a fire of charcoal, coaks, or coals, which have been previously burnt until they have ceased to smoke; which, by giving intense heat and admitting some fresh air, consumes the smoke of the first fire. Lastly, he states his new invention to consist only in the method of consuming the smoke, and increasing the heat, by causing the smoke and flame of the fresh fuel to pass through very hot funnels or pipes, or among, through or near, fuel, which is intensely hot, and which has ceased to smoke; and by mixing it with fresh air when in these circumstances; and in the form and nature of the fire-places above mentioned: the boilers and other parts of the furnaces being such as are in common use. These new invented fire-places are also applicable to furnaces for almost every other purpose.

FURNACE, MR. W. THOMPSON'S STEAM-ENGINE. In vol. iv. of the

of the Repertory is given the following account of a furnace of this sort by Mr. W. Thompson, who describes his invention to be "a furnace which will effectually consume the smoke arising from it, without requiring more coals than usual, as has been the case with former contrivances for that purpose. It may be adapted to any boiler or copper already set up, and at a very small expence. Fig. 8, is a section of an oblong boiler and fire-place. *aaaa*, The brick-work in which boilers are usually set. *AA*, The boiler. Two iron flues run through this boiler, and also go round it. *BB*, The fire-place, which must be about $\frac{1}{2}$ longer than they are generally made. An arch is constructed across the fire-place, two inches lower than the bottom of the flue under the boiler, and about the middle of the fire-place. *DDD*, Flues through which the hot air ascends, and spends its heat upon the boiler. *E*, the door of the fire-place; which must have a small shutter in it. Through this shutter the coals must be gently stirred up, by the slice or poker, taking care not to injure the arch, nor to raise too great a quantity of coals at once. *F* is a small space left behind the fire for a current of air to come through, as in the patent lamps. A brick is placed with its whole length across the fire-place, to hinder the coals from falling down the space *F*, and choking it. Fig. 9, is a front-view of the same boiler and fire-place; in which the same letters represent the same parts. *HH* are two slides, the one shifting backwards, the other forwards, to make the space *F*, for the current of air, larger or smaller, as by practice may be found best. The manner in which this furnace operates is this: the arch hinders the smoke from going up the chimney, and obliges it to pass through the fire behind it; which has a very strong draught, and burns the smoke as it passes through it. The air which comes up through the space *F* gives fresh vigour to the flame, which consumes any smoke that may be left. Too much air will have a very bad effect, as it will cool the flame; therefore the slides *HH* must be regulated in such manner as the operator may find most advantageous. The shutter in the door *E* must also be of a proper size; as its being too large or too small will be prejudicial.

FURNACE, REFINING, a furnace for refining metals. See **METALLURGY**, and **REFINING**. Fig. 10, Plate LXXVII, represents a longitudinal section of this furnace. 1. The masonry of the pillars and walls surrounding the furnace. 2. The channels for carrying off the moisture. 3. Other small channels which join in the middle of the bason. 4. The bason made of bricks. 5. A bed of ashes. 6. The hollow or bason in which the metal is melted and refined. 7. The great flame-hole. 8, 8. The two openings for the entry of the tuyeres of the bellows. 9. The vault or dome of the furnace. 10. The fire-place. 11. The grate. 12. The draught-hole. 13. A hole in the vault, which, being opened, serves to cool the furnace.

FURNACE, REVERBERATORY, FOR SMELTING ORES. Fig. 11, Plate LXXVII, represents a longitudinal section of this furnace. 1. The masonry. 2. The ash-hole. 3. A channel for the evaporation of the moisture. 4. The fire-place. 5. The grate. 6. The inner part of the furnace. 7. A bason formed of sand. 8. The cavity where the melted metal is. 9. A hole through which the scoria is to be removed. 10. The passage of the flame and smoke, or the lower part of the chimney; which is to be carried up to a height of about 30 feet. 11. A hole in the roof, through which the ore is thrown into the furnace. This furnace is 18 feet long, 12 feet broad, and $9\frac{1}{2}$ high. For the purpose of melting large quantities of ore at a time, it was formerly necessary to use bellows of an immense size, which proved inconvenient in several respects. This however has been remedied by a new method of blowing up fires by means of water; which we shall here describe. It depends on the following principle, viz. That a stream of water, running through a pipe, if by any means it is mixed with air at its entrance into the pipe, will carry that air along with it, and part with it again as soon as it comes out of the pipe; and if the air is then collected by a proper apparatus, it may with success be used for exciting the most violent degrees of heat. Machines of this kind are called water-bellows, and are represented Plate LXXVII, fig. 12. In the right hand machine, *AB* represents a stream of water falling into the funnel, whose throat is contracted at *B*; after which the stream runs through the perpendicular pipe *EF*, in the upper part of which there are some small holes represented by *cdef*. Through these holes the air has access to mix itself

with the descending water, which, being dashed against the sides of the pipe, is reduced to froth, and thus fills the whole cavity of the pipe *EF*, which is considerably larger than the throat of the funnel *B*. When this frothy stream enters the vessel *C*, the air extracts itself from the water; and as it cannot return through the pipe *EF*, because it is continually filled with a stream of liquid matter, it flies off with considerable force through the smaller pipe *D*, by which it is conveyed to the furnace. The principal thing, to be kept in view in the construction of these machines, is to mix the descending stream of water, with as great a quantity of air as possible. For this purpose the contrivance represented in the left hand machine answers much better than the former. By this the water descending from the reservoir *A* falls into a kind of cullender *B*, perforated with a great number of holes in its sides. Thus the water being forced out in a number of small streams, is very effectually dashed against the sides of the wide descending pipe, when it enters the condensing vessel *C*, and is sent off by the pipe *D*, as in the former. In some machines of this kind the constructors seem to have been of opinion, that a great height was required in the water-fall; but Dr. Lewis, who has made a great number of experiments upon the subject, shews, that an excess in height can never make up for a deficiency in the quantity of the water. Four or five feet, he thinks, is a sufficient height for the water-fall; where there is a greater height, however, it may be rendered useful, by joining two or more machines together in the manner represented in the plate; where the water, after having once emitted its air in the condensing vessel *C*, flows out into a new reservoir *E*. From thence it descends through another cullender *F*, and descending from it into a condensing vessel *G*, the air is extricated, and carried off through the pipe *H*. The upper figure, *I*, represents the cullender with the shapes of the holes and their proportional distances according to Dr. Lewis. Thus, with very little expence, where there is a sufficient quantity of water, as strong a blast of air as can be desired may be readily obtained; for several machines may be constructed, and joined together in a manner somewhat similar to that above-mentioned, until all the quantity of water is employed. But, as by this method the air is loaded with moisture, it is proper to make the condensing vessel as high as conveniently may be, that the air may arrive at the furnace in as dry a state as possible. The long slender pipes in the left hand machines represent a gauge filled with mercury or water, by which the strength of the blast may be determined. In the large iron founderies another method is used for blowing up the fires by means of a kind of air-pumps. These consist of cast iron cylinders of about three feet diameter, exactly fitted with a piston moved up and down by means of a water-wheel. In the bottom of the cylinder is a large valve like that of bellows, which rises as the piston is lifted up, and thus admits the air into the cavity of the cylinder from below. Immediately above the bottom is a tube which goes to the furnace; and as it proceeds from the cylinder is furnished with a valve opening outward. Thus, when the piston is drawn up, the valve in the bottom rises and admits the air that way into the cylinder, while the lateral valve shuts, and prevents any air from getting into it through the pipe. When the piston is thrust down, the valve in the bottom shuts, while the air being compressed in the cavity of the cylinder is violently forced out through the lateral tube into the furnace. For other furnaces used in chemical operations, see **CHEMISTRY**.

FURUSUND, an island of Sweden, in the Baltic. Lon. 18. 45. E. Lat. 59. 46. N.

FURZE, in botany. See ULEX.

FUSANUS, in botany, a genus of the monœcia order, and polygamia class of plants. The hermaphrodite calyx quinquefid; no corolla; stamina four; germen beneath; fruit a plum. One species.

FUSAROLE, in architecture, a moulding or ornament placed immediately under the echinus, in the Doric, Ionic, and Composite capitals.

FUSEE, [*fuseau*, French,] in clock-work, is that conical part drawn by the spring, and about which the chain or string is wound; for the use of which see CLOCK and WATCH.

FUSIGNANO, a market-town of Italy the late duchy of Ferrara.

FUSIL, in heraldry, a bearing of a rhomboidal figure, longer than the lozenge, and having its upper and lower angles more acute and sharp than the other two in the middle. It is called in Latin *fuscus*, "a spindle," from its shape.

FUSILIERS, FUSILEERS, or FUZILEERS, are armed as the rest of the infantry, but wear caps like the grenadiers, though somewhat shorter. There are three royal regiments of fusiliers in the British service: viz. those of the Scotch fusiliers raised in 1678; of English fusiliers, in 1685; and of Welsh fusiliers, in 1688-9.

FUSION. See CHEMISTRY and FLUIDITY.

FUST, or FAUSTUS, a goldsmith of Mentz, and one of the three earliest printers, to whom the invention of this most useful art has been ascribed. Some say, he only assisted Guttemberg at Strasburg, in his attempts to make moveable types, in 1444. Fust, in partnership with Peter Schoeffer, having, in 1462, printed a considerable number of copies of the Bible, to imitate those which were sold in MS., Fust undertook the sale of them at Paris, where the art of printing was then unknown. At first he sold his copies

for so high a sum as 500 or 600 crowns, the prices usually demanded by the transcribers. He afterwards lowered his price to 60 crowns, which created universal astonishment; but when he produced copies as fast as they were wanted, and lowered the price to 30 crowns, all Paris was agitated. The uniformity of the copies increased the wonder; informations were given into the police against him as a magician; his lodgings were searched; and a great number of copies being found, they were seized: the red ink with which they were embellished, was said to be his blood; it was seriously adjudged that he was in league with the devil; and if he had not fled, most probably he would have shared the fate of those whom ignorant and superstitious judges condemned in those days for witchcraft. Fust is said to have died of the plague at Paris, about 1466.

FUSTIAN, in commerce, a kind of cotton-stuff, which seems as if it were whaled on one side. Fustians should be altogether made of cotton-yarn, both woof and warp; but many pieces are made, the warp of which is flax, or even hemp. Fustians are made of various kinds, wide, narrow, fine, coarse; with shag or nap, and without it.

FUSTICK, in the arts, is the wood of the *morus tinctoria*, a tree that grows to a considerable size in the West Indies. It is much used in dyeing yellow, and produces a large quantity of colouring matter. It is not very hard, and its colour is yellow with orange veins.

FUSTIGATIO, in the Roman customs, a punishment inflicted by beating with a cudgel. This punishment was peculiar to free men; the slaves were scourged with whips.

FUTTOCKS, in a ship, the timbers raised over the keel, or the encompassing timbers that make her breadth. Of these there are the first, second, third, and fourth, denominated according to their distance from the keel, those next it being called first or ground futtocks, and the others upper futtocks; those timbers being put together, make a frame-bend.

FUTTYPOUR SICRI, a considerable town of Hindostan Proper, in the province of Agra, 42 miles W. of Agra.

FUTURE, or FUTURE TENSE, in grammar, denotes an inflexion of verbs, whereby they denote, that a thing will be in some time yet to come. See GRAMMAR.

FYAL, one of the Azores. It is well cultivated, and yields corn, garden-stuffs, and various fruits. It has several kinds of domesticated European animals: the people are cleanly, diligent, and fairer than those of Madeira. The chief town is Villa de Horta. Lon. 28. 36. W. Lat. 38. 32. N.

FYZABAD, a city of Hindostan Proper, in the territory of Oude; 80 miles E. of Lucknow.

G.

G, is the seventh letter of our alphabet, and the fifth consonant. In the alphabets of all the oriental languages, the Hebrew, Phœnician, Chaldee, Syriac, Samaritan, Arabic, and even the Greek, it is the third letter. The Hebrews call it *ghimel*, or *gimel*, i. e. *camel*, because it resembles the neck of that animal; and it bears the same appellation in the Samaritan, Phœnician, Chaldee; in the Syriac it is called *gamel*, in Arabic *gîm*, and in Greek *gamma*. The gamma (γ) of the Greeks is evidently the gimel ($\aleph$) of the Hebrews or Samaritans. The chief difference between the gamma and gimel consists in this, that the one is turned to the right, and the other to the left, according to the different manners of writing and reading which obtained among those nations: though Salmasius, on Solinus, vainly attempted to prove

that the G was derived from the Greek kappa. It is clear that the Latins borrowed their form of this letter from the Greeks; the Latin G being only a variation of the Greek gamma, γ ; as might easily be shewn, had our printers all the forms of this letter, which we meet with in the Greek and Latin MSS. through which it has passed from γ to G. G has two sounds, one called that of the hard G, before a, o, u, l, r; as, *gate*, *go*, *gall*. The other sound, called that of the soft G, resembles that of J, and is commonly, though not always, found before e, i; as, *gem*, *gibbet*. Before n, at the end of a word, g is commonly melted away as in the French, from which these words are commonly derived: thus, for *benign*, *malign*, *condign*, we pronounce *benine*, *maline*, *condine*. It is often silent in the middle of words before h; as, *might*.

might. The Saxon *G, g*, seems to have had generally the sound of *g* consonant; whence *gate* is by rustics still pronounced *yate*. The modern *G* takes its form from that of the Latins. It is a mute, and cannot be sounded at all without the help of a vowel. Its hard sound is formed by the reflection of the air against the palate, made by the tongue as the air passes out of the throat; which Martianus expresses thus, *G spiritus cum palato*; so that *G* is a palatal letter. *G* often sounds hard before *i*, as *give*, &c. and sometimes before *e*, as *get*, &c. It is also hard in derivatives from words ending in *g*, as *singing*, *stronger*, &c. and generally before *er*, at the end of words, as *finger*. *G* is mute before *n*, as *gnash*, *sign*. *Gh* has the sound of hard *G* in the beginning of a word, as *ghostly*; sometimes at the end it is quite silent, as *though*. But at the end of many other words *Gh* has the sound of *f*, as *laugh*, *rough*, *tough*, &c. As an abbreviation, *G* stands for *Gaius*, *Gellius*, *gens*, *genius*, &c. *G. G.* for *gemina*, *gessit*, *gesserunt*, &c. *G. C.* for *genio civitatus* or *Casaris*. *G. L.* for *Gaius libertus*, *gentio loci*. *G. V. S.* for *genio urbis sacrum*. *G. B.* for *genio bono*. And *G. T.* for *genio tutelari*. In music, *G* is the character or mark of the treble cleff; and from its being placed at the head, or marking the first sound in Guido's scale, the whole scale took the name *Gamut*. As a numeral, *G* was anciently used to denote 400; and with a dash over it, thus *G̃*, for 40,000.

GAAL, [Hb. Hebrew, *i. e.* an abomination,] the son of Ebed, the leader of the conspiracy of the Shechemites against the usurper Abimelech, the son of Gideon. See Judges, ix. 26—41.

GABALE, in mythology, a deity worshipped at Heliopolis under the figure of a lion, with a radiant head; and it is thus represented on many medals of Caracalla.

GABARA, or **GABBARA**, in antiquity, the dead bodies which the Egyptians embalmed, and kept in their houses.

GABARET, a town of France, in the department of Landes, 15 miles W. of Condom.

GABEL, [Lat. *Gabella*, *Gabium*, *Gablagium*, *i. e.* *Vectigal*,] has the same signification among the ancient English writers, that *Gabelle* had in France, before the revolution. It has been variously used, for a rent, custom, service, &c. Where it was a payment for rent, those who paid it were termed *Gablatores*. Formerly when mentioned without any addition, *gabel* signified the tax on salt, though afterwards it was applied to all other taxes. In the late French customs, the *gabelle*, or tax on salt, is said to have had its rise in 1286, under Philip IV. It was afterwards so greatly advanced by the succeeding kings, that at length it was estimated to constitute $\frac{1}{4}$ of the whole revenue of the kingdom; so that a minot of salt at last paid a duty of 52 livres, 8 sols, and 6 deniers. Philip VI. first established granaries and officers of the *gabelles*, and prohibited all others from selling salt. From that period, the commerce of salt for inland consumption continued wholly in the king's hands, every grain of it being sold by his farmers. This very odious and oppressive tax was early abolished by the National Assembly.

GABEL, in geography, a town of Bohemia, in the circle of Boleslaw, 45 miles N. of Prague.

GABELLE. See **GABEL**.

GABINIAN LAWS, in Roman antiquity, laws instituted upon several occasions by persons of the name of *Gabinus*.

GABINUS CINCTUS, in Roman antiquity, a particular way of tucking the gown, by drawing it forwards on the breast, and tying it into a knot: as the people of *Gabii* did at a solemn sacrifice, on the sudden attack of an enemy, in order to be fitter for action.

GABIONS, in fortification, are baskets made of osier-twigs, of a cylindrical form, six feet high and four wide; which, being filled with earth, serve as a shelter from the enemy's fire.

GABLE, or **GABLE-END**, of a house, is the upright triangular end from the cornice or eaves to the top of the house.

GABRES, or **GAVRES**, a religious sect in Persia and India; called also *Gebres*, *Guebres*, *Gevres*, *Gaurs*, &c. See **MAGI**. Those of this sect are dispersed through the country, and said to be the remains of the ancient Persians, or followers of Zoroaster, being worshippers of fire.

GABRES is also a name given by the Turks to the Christians, signifying infidels, or people of a false religion.

GABRIELITES, in ecclesiastical history, a sect of anabap-

tists that appeared in Pomerania, in 1530; so named from *Gabriel Scherling*; who, after having been for some time tolerated in that country, was obliged to remove, and died in Poland.

GAD, [Hb. *i. e.* a troop,] one of the 12 patriarchs, the son of Jacob by *Zilpah*, and progenitor of the tribe of the *Gadites*.

GAD, in ancient geography, a district of Transjordan Palestine, situated between Gilead and the kingdom of Bashan on the N. and that of the Amorites to the S. having the Jordan to the W. and bounded by various nations on the E. so called from the tribe of that name.

GAD, among miners, a small punch of iron, with a long wooden handle, used to break up the ore. One of the miners holds this in his hand, directing the point to a proper place, while the other drives it into the vein, by striking it with a sledge-hammer.

GADARA, in ancient geography, a strong town of the *Peæa*, in Decapolis, restored by Pompey after its demolition by the Jews.

GAD-BEE, or **GAD-FLY**. See **OESTRUS**.

GADEBUSCH, a town of Germany, 16 miles W. N. W. of Schwerin.

GADEMIR, or **GADEMIS**, a country of Africa, W. of Fezzan, containing 92 towns and villages.

GADEMIS, or **GADEMIR**, the capital of the above country, lies 300 miles from the sea-coast.

GADES, or **GADIRA**, in ancient geography, a small island in the Atlantic, on the Spanish coast, 25 miles from the Pillars of Hercules.

GADOLINITE, a mineral first found in a white felspar in the quarry of Ytterby in Sweden, and was called *gadolinite*, from *Gadolin* who first ascertained its composition. Colour perfect black, passing sometimes to brown. Found in mass. Fracture conchoidal. Scratches quartz. Brittle. Specific gravity 4.0497. Gelatinizes with hot diluted nitric acid. Before the blow-pipe decrepitates, and assumes a whitish red colour, but does not melt. With borax it melts into a topaz-yellow glass. Affects the magnetic needle. A new earth called *Yttria*, from the place where it is formed, has been discovered in it. According to the analysis of *Vauquelin*, it is composed of:

35.0	yttria
25.5	silica
25.0	oxide of iron
2.0	lime
2.0	oxide of manganese
10.5	water and carbonic acid

100.0

Klaproth, on the other hand, found

59.75	yttria
21.25	silica
18.00	oxide of iron
0.50	alumina

99.50

GADONA, or **GADUA**, a country of Africa, S. of the Senegal, containing mines of gold, iron, and nitre.

GADUS, in ichthyology, the *CON*, a genus of fishes of the order *jugulares*. Generic character: the head smooth; gill-membrane, seven-rayed; body oblong, covered with deciduous scales; fins all covered by the common skin; more than one dorsal fin, of which the rays are unarmed; ventral fins slender and ending in a point. There are twenty-three species; the most remarkable are these,

G. BARBATUS, the *POUT*, never grows to a large size, seldom exceeding a foot in length. It is distinguished from all others by its great depth; one of the size above-mentioned being near four inches deep in the broadest part. The colour of the body is white; but more obscure on the back than the belly, and tinged with yellow. It is called at Scarborough a *kleg*, and is a very delicate fish.

G. EGLESINUS, the *HADDOCK*, has a long body; the upper part of a dusky brown colour, and the belly and lower part of the sides silvery. On the back are three fins resembling those of the common cod-fish; the lateral line is black; and the tail is forked.

The

The head slopes down to the nose; on the chin is a short beard; and on each side beyond the gills is a large black spot. The fishermen assert, that in rough weather haddocks sink down into the sand and ooze in the bottom of the sea, where they shelter themselves till the storm is over; for in stormy weather they take none; and those that are taken immediately after a storm have mud on their backs. In summer they live on young herrings and other small fish; in winter on the stone-coated worms, a species of *Serpula*, which the fishermen call haddock-meat. The grand shoal of haddocks comes periodically on the Yorkshire coast. It is remarkable that they appeared in 1766, on the 10th of December, and exactly on the same day in 1767: these shoals extended from the shore near three miles in breadth, and in length from Flamborough head to Tinmouth castle, and perhaps much farther northwards. An idea may be given of their numbers by the following fact: Three fishermen, within the distance of a mile from Scarborough harbour, frequently loaded their boat with them twice a-day, taking each time about a ton of fish; when they put down their lines beyond the distance of three miles from the shore, they caught nothing but dog-fish, which shews how exactly these fish keep their limits. The best haddocks were sold at from 8d. to 1s. per score, the smaller sort at a penny and even a halfpenny per score.

G. LOTA, the **BURBOT**, in its body has some resemblance to an eel, only shorter and thicker; and its motions also resemble those of that fish: they are besides very smooth, slippery, and slinky. The head is very ugly, being flat, and shaped like that of a toad: the teeth are very small, but numerous. On the end of the nose are two small beards; on the chin another.

G. MERLANGUS, the **WHITING**, is a fish of an elegant make: the upper jaw is the longest; the eyes are large, the nose is sharp: the teeth of the upper jaw are long, and appear above the lower when closed. The colour of the head and back is a pale brown; the lateral line white, and crooked; the belly and sides are silvery, the last streaked lengthwise with yellow. These fish appear in vast shoals in spring, keeping at the distance of about half a mile to that of three from the shore. They are caught in vast numbers by the line, and afford excellent diversion. They are the most delicate, as well as the most wholesome, of any of the genus: but they do not grow to a large size, the biggest not exceeding 20 inches; the usual length being 10 or 12.

G. MERLUCIUS, the **HAKE**, is found in vast abundance on many of our coasts, and those of Ireland. There was formerly a vast stationary fishery of hake on the Nymph Bank off Waterford; immense quantities appearing there twice a-year; the first shoal coming in June, during the mackerel-season; the other in September, at the beginning of the herring-season, probably in pursuit of those fish: it was usual for six men with hooks and lines to take a 1000 hakes in one night, besides a considerable quantity of other fish. These were salted and sent to Spain, particularly to Bilbao.

G. MOLVA, the **LING**, is usually from three to four feet long, but have been caught seven feet long. The body is very slender; the head flat: the upper jaw is longest; the teeth in that jaw are small and very numerous; in the lower, few, slender, and sharp: on the chin is a small beard. They vary in colour, some being of an olive hue on the sides and back, others cinereous: the belly white. The ventral fins are white: the dorsal and anal edged with white. The tail is marked near the end with a transverse black bar, and tipped with white. Its English name *ling* is derived from its length, being a corruption of long. It abounds about the Scilly Isles, on the coasts of Scarborough, Scotland and Ireland, and forms a great branch of trade.

G. MORHUA, or the **COMMON COD**, inhabits the northern seas, both of Europe and America, in innumerable shoals, and constitutes an important article of human subsistence. Its general length is from two to three feet, and its common weight from fourteen to thirty pounds. It has occasionally, however, been known to weigh upwards of seventy. Its food consists of small fish, worms, crabs, and other testaceous fishes, and its voracity is extraordinary. It is prolific in the extreme, no less than a million of eggs having been counted in a single roe. Its sound, or air-bladder, is preserved with salt, and considered as a luxury; it is also converted into a sort of isinglass, in preparing which the inhabitants of Iceland are particularly skilful. Off the coasts of Cape Breton, Nova Scotia, and New England, and, more especially, on the great sand-bank off

Newfoundland, this fish is found in inexhaustible abundance; the neighbourhood of the Polar Seas, where they return to deposit their spawn, and the immense number of worms to be found in these sandy bottoms being the grand inducements to their preference of these situations. They are abundant also on the southern and western coasts of Iceland, but proceed towards the south only in very diminished numbers, and are rarely seen in that direction beyond the Straights of Gibraltar. Before the discovery of Newfoundland, in 1496, Iceland was the principal scene for the cod-fishery, which was speedily after that event transferred to Newfoundland, where it is conducted to such an extent, merely by the hook, baited with the herring and other small fishes, as to furnish employment for fifteen thousand British seamen, and to a more numerous portion of population at home, occupied on the various articles of manufacture, indispensable for a concern of such vast extent and importance.

G. POLLACHIUS, the **POLLACK**, has the under jaw longer than the upper; the head and body rises pretty high, as far as the first dorsal fin. The side-line is incurvated, rising towards the middle of the back, then sinking and running straight to the tail; it is broad and of a brown colour. The colour of the back is dusky, sometimes inclining to green: the sides beneath the lateral line are marked with lines of yellow; and the belly is white. This species is common on many of our rocky coasts: during summer they are seen in great shoals frolicking on the surface of the water, and flinging themselves into a thousand forms. They will then bite at any thing that appears on the top of the waves, and are often taken with a goose-feather fixed to the hook. They are very strong, being observed to keep their station at the feet of the rocks in the most turbulent and rapid sea. They are good eating. They do not grow to a very large size; the biggest seldom exceeding six or seven pounds.

GAEL, a town of France in the department of Ille and Vilaine, 1 mile S. of St. Maen, and 10 W. of Montfort.

GAELIC, belonging to the Gaels, Celtes, or ancient Scots Highlanders.

GAELICK LANGUAGE, the language of the ancient and modern Highlanders of Scotland. It is esteemed the most ancient as well as the purest dialect of the Celtic, now spoken. It has all the marks of an original language. Most of its words are expressive of some property or quality in the objects which they denote. This, with the variety of its sounds, (many of which, especially those that express the soft and mournful passions, are peculiar to it,) renders it highly adapted for poetry. It was the language of the Scottish Court, till the reign of Malcolm Canmore, and was even spoken so late as that of Robert Bruce, particularly in a parliament held by him at Ardochattan. Its alphabet consists of 18 letters, of which five are vowels. "Those who understand it, (says the Rev. Dr. James Robertson, of Callander,) know its energy and power; the ease with which it is compounded; the boldness of its figures; its majesty in addressing the Deity, and its tenderness in expressing the finest feelings of the human heart. But its genius and constitution, the structure of its nouns and verbs, and the affinity it has to some other languages are not so much attended to. These point at a very remote æra, and seem to deduce its origin from a very high antiquity. The verbs have only three tenses, which is the simplest and most natural division of time. The persons of each tense are distinguished, by adding pronominal particles to each person. The third person singular of each verb has genders, or admits of a masculine and feminine particle affixed. The moods are the indicative, imperative, and infinitive. The subjunctive differs from the indicative only by the addition of one syllable to the verb, and a conjunction before it. The imperative has only the second person in both numbers. The infinitive is often used as a substantive noun, expressive of the abstract signification of the verb. There is only one conjugation, and one declension. The cases of the nouns are marked by different particles, or by a change of the last vowel. The degrees of comparison are formed by placing certain syllables before the adjective; and the superlative frequently by a repetition of the positive."

GARTNERE, a genus of the decandria monogynia class and order. The calyx is five parted; corolla five-petaled: seed-vessel nearly globose, with wings. There is one species, a shrub of the East Indies.

GAETA,

GAETA, an ancient, and strong town of Naples, in Lavoro, 40 miles of Naples.

GÆTULI, the people of Gætulia, were among the earliest inhabitants of Africa. They were distinguished by different epithets; as Nigri, Autolotes, Dara, and Baniuræ. (Pliny.)

GÆTULIA, in ancient geography, a country of Africa, lying S. of Mauritania, divided into Gætulia Propria, and Gætulia Vetus.

GAFF, a sort of boom or bole, frequently used in small ships, to extend the upper edge of the mizen; and always employed for the same purpose on those sails, whose foremost edges are joined to the mast by hoops or lacings, and which are usually extended by a boom below. Such are the main-sails of all sloops, brigs, and schooners.

GAGE, in our ancient customs, is only properly used in speaking of moveables; for immoveables, Hypotheca is used. If the gage perish, the person who received it is not to answer for it, but only for extreme negligence, &c.

GAGE is also used for a challenge to combat. It was a pledge, which the accuser or challenger cast on the ground, and the other took up as accepting the challenge; being usually a glove, gauntlet, chaperoon, or the like.

GAGE, among letter-founders, a piece of box, or other hard wood, variously notched: used to adjust the dimensions, slopes, &c. of the different sorts of letters.

GAGE, in joinery, an instrument made to strike a line truly parallel to the straight side of any board or piece of stuff. Its chief use is for the gaging of tenons true, to fit into mortises; and for gaging stuff of an equal thickness. It is made of an oval piece of wood, fitted upon a square stick, to slide up and down stiffly thereon, and with a tooth, at the end of a staff, to score, to strike a line upon the stuff at any distance, according to the distance of the oval from it.

GAGE, in the sea-language. When one ship is to the windward of another, she is said to have the weather-gage of her. They likewise call the number of feet that a vessel sinks in the water the ship's gage; this they find by driving a nail into a pike near the end, and putting it down beside the rudder till the nail catch hold under it; then as many feet as the pike is under water is called the ship's gage.

GAGE, AQUEO-MERCURIAL, an apparatus contrived by Dr. Hales, and applied in various forms to the branches of trees, to determine the force with which they imbibe moisture. In Plate LXXVIII. fig. 1, *e, r*, is a cylindric glass, *e, g*, of an inch diameter within, and eight inches long. Into this glass is introduced the branch of a young thriving apple-tree, *b*, about three feet long, with lateral branches; the diameter of the transverse cut *i* being three-fourths of an inch. Having fitted the joint *r* to the tube at *r*, by folding a piece of sheep's skin round the stem, it is cemented with a mixture of bees-wax and turpentine melted together, in such proportion as to make a very stiff clammy paste when cold, and over the cement folds of wet bladders are bound firmly with pack-thread. To the lower end *e* of the large tube, a smaller tube *z e* is cemented, being about $\frac{1}{2}$ of an inch diameter, and 18 inches long, and in substance full $\frac{1}{3}$ of an inch thick. These tubes are cemented together at *e*, with common hard brick-dust, or powdered chalk cement, and the joint is farther secured with the cement of bees-wax and turpentine, over which a wet bladder is bound. The apparatus being thus prepared, the branch is turned downwards, and the glass-tube upwards, and then both tubes are filled with water; with the finger applied to the open end of the small tube, it is inverted and immersed in the glass-cistern *x*, full of mercury and water. In this situation the lower end of the branch was immersed six inches in water, viz. from *r* to *i*; the water was imbibed by the branch at its transverse cut *i*; and during its ascent into the sap-vessels of the branch, the mercury rose in the tube *e z* from the cistern *x*, so that in half an hour it was risen $5\frac{1}{2}$ inches high, as far as *z*. The height of the mercury indicated, in some measure, the force with which the sap was imbibed, though not the whole force; because, while the water was imbibed by the branch, its transverse cut was covered with innumerable little hemispheres of air, and many air-bubbles issued out of the sap-vessels, which partly filled the tube *e r*, as the water was drawn out of it: and therefore the height of the mercury could only be proportionable to the excess of the quantity of water drawn off, above the quanti-

ty of the air which issued out of the wood. If the quantity of air issuing from the wood had been equal to the quantity of water imbibed, it is plain that the mercury could not rise at all, because there would be no room for it in the tube: but if 9 parts in 12 of the water be imbibed by the branch, and only three such parts of air issue into the tube in the same time, the mercury must rise near six inches, and so proportionably in other cases. Dr. Hales observed, that the mercury rose highest, in most cases, when the sun was clear and warm, and that it subsided three or four inches towards evening, but rose again the next day as it grew warm, though seldom so high as at first. He adapted the size and shape of the glass apparatus to a great variety of branches of several sizes and of different kinds of trees, and repeated the experiment above described, *mutatis mutandis*, in a variety of instances. See his *Vegetable Statics*, vol. i. chap. ii. p. 84, &c.

GAGE, BUCKET SEA, an instrument contrived by Dr. Hales to find the different degrees of coolness and saltness of the sea, at different depths. It consists of a common household pail or bucket, with two heads; which have each a round hole in the middle, about four inches in diameter, covered with square valves opening upward; and that they may both open and shut together, there is a small iron rod fixed to the upper part of the lower valve, and the other end to the lower side of the upper valve. So that as the bucket descends with its sinking weight into the sea, both the valves may open by the force of the water, which thus has a free passage through the bucket. But when the bucket is drawn up, then both the valves shut by the force of the water at the upper part of the bucket; so that the bucket is drawn up full of the lowest sea-water to which it has descended. When the bucket is drawn up, the mercurial thermometer fixed in it is examined; but great care must be taken to observe the degree at which the mercury stands, before the lower part of the thermometer is taken out of the water in the bucket, lest it be affected by the different temperature of the air. To keep the bucket in a right position, there are four cords fixed to it, reaching about three feet below it; to which the sinking weight is fixed. The result of several trials with this gage was, that when it was let down to different depths, from 360 feet to 5,346 feet, in lat. 25. 13. N. and lon. 25. 12. W. it was discovered by the thermometer, that the cold increased gradually in proportion to the depths, till it descended to 3,900 feet, viz. near three-fourths of a mile, whence the mercury in the thermometer came up at 53°; and though it afterwards sunk to 5,346 feet, i. e. a mile and 66 feet, it came up no lower: the warmth of the water upon the surface, and that of the air, was all that time 84°. When the water in the bucket was become of the same temperature with that on the surface of the sea, equal quantities of both were weighed and tried by the hydrometer; that from below was found to be the heaviest, and consequently the saltest. Dr. Hales was probably led to the construction of this sea-gage from an instrument invented by Dr. Hook, and designed for the same purpose. See Plate LXXVIII. fig. 2. This consists of a square wooden bucket *C*, whose bottoms are so contrived, that as the weight *A* sinks the iron *B*, to which the bucket *C* is fastened by two handles *D, D*, on the end of which are the moveable bottoms or valves *E E*, and thereby draws down the bucket, the resistance of the water keeps up the bucket in the posture *C*, whereby the water, whilst the bucket is descending, hath a free passage through it; whereas, as soon as the bucket is pulled upwards by the line *F*, the resistance of the water to that motion beats the bucket downwards, and keeps it in the posture *G*, whereby the included water is kept from getting out, and the ambient water kept from getting in. Phil. Trans. N° 9, p. 149, and N° 24, p. 447, or Abr. vol. ii. p. 260.

GAGE, SEA, an instrument invented by Dr. Hales and Dr. Desaguliers for finding the depth of the sea; the description whereof is this: *AB*, Plate LXXVIII. fig. 3, is the gage-bottle, in which is cemented the gage-tube, *F f*, in the brass cap at *G*. The upper end of the tube *F* is hermetically sealed, and the open lower end *f* is immersed in mercury, marked *C*, on which swims a small thickness or surface of treacle. On the top of the bottle is screwed a tube of brass *H G*, pierced with several holes to admit the water into the bottle *AB*. The body *K* is a weight hanging by its shank *L*, in a socket *N*, with a notch on one side at *m*, in which is fixed the catch *l* of the spring *S*, and, passing through the hole *L*, in the shank of the weight *K*, prevents its falling out when once hung

on. On the top, in the upper part of the brass tube at H, is fixed a large empty ball, or full blown bladder I, which must not be so large but that the weight K may be able to sink the whole under water. The instrument thus constructed is used in the following manner. The weight K being hung on, the gage is let fall into deep water, and sinks to the bottom; the socket N is somewhat longer than the shank L; and therefore, after the weight K comes to the bottom, the gage will continue to descend till the lower part of the socket strikes against the weight; this gives liberty to the catch to fly out of the hole L, and let go the weight K: when this is done, the ball or bladder I instantly buoys up the gage to the top of the water. While the gage is under water, the water having free access to the treacle and mercury in the bottle, will by its pressure force it up into the tube Ff, and the height to which it has been forced by the greatest pressure, viz. that at the bottom, will be shewn by the mark in the tube which the treacle leaves behind it, and which is the only use of the treacle. This shews into what space the whole air in the tube Ef is compressed, and consequently the height or depth of the water which by its weight produced that compression, which is the thing required. If the gage-tube Ff be of glass, a scale might be drawn on it with the point of a diamond, shewing, by inspection, what height the water stands above the bottom. But the length of ten inches is not sufficient for fathoming depths at sea, since that, when all the air in such a length of tube is compressed into half an inch, the depth of water is no more than 634 feet, which is not half a quarter of a mile. If, to remedy this, we make use of a tube fifty inches long, which for strength may be a musket-barrel, and suppose the air compressed into a hundredth part of half an inch; then by saying, 1 : 99 :: 400 : 39600 inches, or 3300 feet; even this is but little more than half a mile, or 2640 feet. But since it is reasonable to suppose the cavities of the sea bear some proportion to the mountainous parts of the land, some of which are more than three miles above the earth's surface; therefore, to explore such great depths, the doctor contrived a new form for his sea-gage, or rather for the gage-tube in it, as follows: BCDE, fig. 4, is a hollow metalline globe communicating on the top with a long tube, AB, whose capacity is a ninth part of that globe. On the lower part, at D, it has also a short tube DE, to stand in the mercury and treacle. The air contained in the compound gage-tube is compressed by the water as before; but the degree of compression, or height to which the treacle has been forced, cannot there be seen through the tube; therefore, to answer that end, a slender rod of metal or wood, with a knob on the top of the tube AB, will receive the mark of the treacle, and shew it when taken out. If the tube AB be fifty inches, and of such a bore that every inch in length should be a cubic inch of air, and the contents of the globe and tube together 500 cubic inches; then when the air is compressed within a hundredth part of the whole, it is evident the treacle will not approach nearer than five inches of the top of the tube, which will agree to the depth of 3300 feet of water as above. Twice this depth will compress the air into half that space nearly, viz. two inches and a half, which correspond to 6600, which is a mile and a quarter. Again, half that space, or one inch and a quarter, will shew double the former depth, viz. 13200 feet, or two miles and a half; which is probably very nearly the greatest depth of the sea.

GAGE, WIND, an instrument for measuring the force of the wind upon any given surface. It was invented by Dr. Lind, who gives the following description of it, Philosophical Transactions, vol. lxxv. See Plate LXXVIII. fig. 5. This instrument consists of two glass-tubes, AB, CD, of five or six inches in length. Their bores, which are so much the better for being equal, are about four-tenths of an inch in diameter. They are connected together like a siphon, by a small bent glass-tube, *ab*, the bore of which is about one-tenth of an inch in diameter. On the upper end of the leg AB there is a tube of latten brass, which is kneed, or bent perpendicularly outwards, and has its mouth open towards F. On the other leg CD is a cover with a round hole G in the upper part of it, two-tenths of an inch in diameter. This cover and the kneed tube are connected together by a slip of brass *ed*, which not only gives strength to the whole instrument, but also serves to hold the scale III. The kneed tube and cover are fixed on with hard cement, or sealing-wax. To the same tube is soldered a piece of brass *e*, with a round hole in it to receive the steel spindle KL; and at *f* there is just another piece of

brass soldered to the brass hoop *gh*, which surrounds both legs of the instrument. There is a small shoulder on the spindle at *f*, upon which the instrument rests, and a small nut at *i*, to prevent it from being blown off the spindle by the wind. The whole instrument is easily turned round upon the spindle by the wind, so as always to present the mouth of the kneed tube towards it. The end of the spindle has a screw on it; by which it may be screwed into the top of a post or a stand made on purpose. It has also a hole at *L*, to admit a small lever for screwing it into wood with more readiness and facility. A thin plate of brass *k*, is soldered to the kneed tube, about half an inch round the hole G, so as to prevent rain from falling into it. There is likewise a crooked tube AB, fig. 6, to be put occasionally upon the mouth of the kneed tube F, to prevent rain from being blown into the mouth of the wind-gage when it is left out all night, or exposed in the time of rain. The force or momentum of the wind may be ascertained by this instrument, by filling the tubes half full of water, and pushing the scale a little up or down, till the 0 of the scale, when the instrument is held up perpendicularly, be on a line with the surface of the water in both legs of the wind-gage. The instrument being thus adjusted, hold it up perpendicularly, and turning the mouth of the kneed tube towards the wind, observe how much the water is depressed by it in the one leg, and raised in the other. The sum of the two is the height of a column of water which the wind is capable of sustaining at that time; and every body that is opposed to that wind will be pressed upon by a force equal to the weight of a column of water having its base equal to the altitude of the column of water sustained by the wind in the wind-gage. Hence the force of the wind upon any body, where the surface opposed to it is known, may be easily found, and a ready comparison may be made betwixt the strength of one gale of wind and that of another. The force of the wind may likewise be measured with this instrument, by filling it until the water runs out at the hole G. For if we then hold it up to the wind as before, a quantity of water will be blown out; and if both legs of the instrument are of the same bore, the height of the column sustained will be equal to double the column of water in either leg, or the sum of what is wanting in both legs. But if the legs are of unequal bores, neither of these will give the true height of the column of water which the wind sustained. But the true height may be obtained by the following formulæ. Suppose that after a gale of wind which had blown the water from A to B, fig. 7, forcing it at the same time through the other tube out at E, the surface of the water should be found standing at some level DG, and it were required to know what was the height of the column EF or AB, which the wind sustained. In order to obtain this, it is only necessary to find the height of the columns DB or GF, which are constantly equal to one another; for either of these added to one of the equal columns AD, EG, will give the true height of the column of water which the wind sustained. I. Let the diameters AC, EH, of the tubes be respectfully represented by *c* and *e*; and let *a* = AD, or EG, and *x* = DB, or GF: then it is evident that the column DB is to the column EG, as *c*²*x* to *e*²*a*. But these columns are equal. Therefore *c*²*x* = *e*²*a*; and conse-

quently $x = \frac{e^2 a}{c^2}$. II. But if at any instant of time whilst the

wind was blowing, it was observed, that, when the water stood at E, the top of the tube out of which it is forced, it was depressed in the other to some given level BF, the altitude at which it would have stood in each, had it immediately subsided, may be found in the following manner: Let *b* = AB or EF. Then it is evident that the column DB is equal to the difference of columns EF, GF. But the difference of these columns is as *b*² - *d*²*x*; and consequently $x = \frac{b^2 - d^2}{c^2 + d^2}$. For the cases when the wind blows

in at the narrow leg of the instrument: Let AB = EF = *b*, EG, or AD = *a*, GF = DB = *x*, and the diameters EH, GA, respectively = *d*, *c*, as before. Then it is evident that the column AD is to the column GF as *a*² to *d*²*x*. But the columns are equal;

therefore $d^2 x = a^2$; and consequently $x = \frac{a^2}{d^2}$. It is also evi-

dent that the column AD is equal to the difference of the columns AB,

AB, DB; but the difference of these columns is as $bc^2 - c^2x$.

Therefore, $d^2x = bc^2 - c^2x$. Whence we get $x = \frac{bc^2}{d^2 + c^2}$. The

use of the small tube of communication ab , fig. 5, is to check the undulation of the water, so that the height of it may be read off from the scale with ease and certainty. But it is particularly designed to prevent the water from being thrown up to a much greater or less altitude, than the true height of the column which the wind is able at that time to sustain, from its receiving a sudden impulse whilst it is vibrating in its ascent or descent. As in some cases the water in this instrument might be liable to freeze, and thus break the tubes, Dr. Lind recommends a saturated solution of sea-salt to be used instead of it, which does not freeze till Fahrenheit's thermometer falls to 0.

GAGO, a fertile kingdom of Africa, in Negroland, abounding in corn and gold.

GAGO, the capital of the above kingdom.

GAHNIA, in botany, a genus of the monogynia order, and hexandria class of plants. Calyx, an involucre with two or five flowers; corolla two-valved; antheræ linear, sharp-pointed at the apex, as long as the corolla; seed single and oblong. There are two species.

GAIA, or **GAJA**, a town of Italy situated, 20 miles S. of Modena.

GAILLAC, a town of France, in the department of Tarn, 8 miles N.N.W. of Castres, and 27 N.E. of Toulouse.

GAILLON, a town of France, in the department of Eure, $7\frac{1}{2}$ miles S. E. of Louviers, 9 N. W. of Vernon, and 22 from Rouen.

GAIN, in architecture, is the workmen's terms for the bevelling-shoulder of a joist or other timber. It is used also for the lapping of the end of the joist, &c. upon a trimmer or girder; and then the thickness of the shoulder is cut into the trimmer, also bevelling upwards, that it may just receive the gain; and so the joist and trimmer lie even and level with the surface. This way of working is used in floors and hearths.

GAIN THE WIND, in sea-language, is to arrive on the weather-side or to windward of some other vessel in sight, when both are plying to windward, or sailing as near the wind as possible.

GAINAGE, or **GAINAGIUM**, in ancient writers, signifies the draught-oxen, horses, wain, plough, and furniture, for carrying on the work of tillage by the sokemen and villains. Gainage is the same with wainage.

GAINAGE, is also used for the land itself, or the profit raised by cultivating it.

GAINSBOROUGH, a town of Lincolnshire, 18 miles N. W. of Lincoln. Lon. O. 40. W. Lat. 53. 27. N.

GALACTOPHAGI, and **GALACTOPOTÆ**, [from *γαλακτο*, milk; *φαγω*, to eat; and *ποτος* of *πινω*, I drink,] in antiquity, persons who lived wholly on milk, without corn or any other food. Certain nations in Scythia Asiatica, as the Getae, Nomades, &c. are famous in ancient history, as galactophagi.

GALACZ, **GALASI**, or **GALATZ**, a town of European Turkey, in Bulgaria, near the Danube, 20 miles S. S. W. of Bender.

GALANGAL. See **KEMPFERIA**.

GALANTHUS, the **SNOW-DROP**; in botany, a genus of the monogynia order, and hexandria class of plants; natural order, Spahacæ. Petals three, concave; nectarium consists of three emarginated petals; stigma simple. There is but one species, *G. Nivalis*, a bulbous-rooted flowery perennial, rising but a few inches in height, and adorned at top with small tripetalous flowers of a white colour. There are three varieties, viz. the common single-flowered snow-drop, the semi-double snow-drop, and the double snow-drop. They are beautiful little plants; and are much valued on account of their early appearance, often adorning the gardens in January or February, when scarce any other flower is to be seen.

GALARDIA, a genus of the class and order syngenesia polygamia frustranea. The receptacle is chaffy; seed crowned with a five-leaved calycle; calyx, two rows of scales, almost equal. There is one species, an annual of Louisiana.

GALATA, an island near the coast of Tunis. Lon. 9. 30. E. Lat. 38. 15. N.

GALATÆA, or **GALATHÆA**, in mythology, a sea-nymph,

daughter of Nereus and Doris. She was beloved by the Cyclops Polyphemus, whom she treated with disdain; while Acis, a shepherd of Sicily, enjoyed her affection.

GALATIA, the ancient name of a province of Asia Minor, now called Amasia. It was bounded on the E. by Cappadocia, on the S. by Pamphylia, on the N. by the Euxine sea, and on the W. by Bithynia.

GALAX, in botany, a genus of the monogynia order, and pentandria class of plants. Corolla salver-shaped; calyx decaphyllous; capsule unilocular, bivalved, and elastic. One species, viz. *G. aphylla*.

GALAXIA, a genus of the monodelphia triandria class and order. Spatha one-valved; corolla one-petaled, six-cleft; tube capillary; stigma many-parted. There are two species, herbs of the Cape.

GALAXY, that long white luminous track, which seems to encompass the heavens like a girdle; and is easily perceivable in a clear night, especially when the moon does not shine. The Greeks called it *Γαλαξίας*, of *Γαλα*, *γαλακτο*, milk, and the Romans via lactea, the milky way, on account of its colour and appearance. And their poets told many fables about the spilling of Juno's milk, &c. as the cause of its whiteness. It passes between Sagittarius and Gemini, and divides the sphere into two parts; it is unequally broad; in some parts single, in others double. The ancient poets, and even philosophers, speak of the Galaxy as the road by which the heroes went to heaven. Aristotle supposed it a kind of meteor, formed of a crowd of vapours, drawn into that part by certain large stars disposed in the region of the heavens answering hereto. Others, finding that the Galaxy was seen all over the globe, that it always corresponded to the same fixed stars, and that it transcended the height of the highest planets, set aside Aristotle's opinion; placed the Galaxy in the firmament, or region of the fixed stars, and concluded it to be nothing but an assemblage of an infinite number of minute stars. Since the invention of the telescope, this opinion has been abundantly confirmed. By directing a good telescope to any part of the milky way, where before we only saw a confused whiteness, we now descry an innumerable multitude of little stars, so remote, that a naked eye confounds them. See **ASTRONOMY**.

GALBANUM, a gum-resin which issues from the stem of an umbelliferous plant, growing in Persia, and many parts of Africa. See **BUBON**. The juice is semi-pellucid, soft, tenacious; of a strong smell, and a bitterish warm taste; the better sort is in pale-coloured masses, composed of clear white tears. Galbanum agrees in virtue with gum ammoniac, but is generally accounted less efficacious in asthmas, and more so in hysterical complaints. It is an ingredient in the gum-pills, the gum-plaster, and some other official compositions.

GALBULAR, the **JACAMAR**, in natural history, a genus of birds of the order Picæ. Bill straight, very long, quadrangular, and pointed; nostrils situated near the base of the bill, and oval; tongue pointed and short; legs feathered before, down to the toes; feet formed for climbing. There are four species. *G. alcedo*, is about the size of a lark, and is of a most elegant and brilliant plumage. It is found in the damp places of the woods of Guiana and Brazil.

GALE, **THOMAS**, D. D. and F. R. S. a learned divine, born at Scruton, in Yorkshire, in 1636. He was educated at Cambridge, and afterwards chosen head-master of St. Paul's school, London; and wrote those elegant inscriptions on the monument erected in memory of the conflagration in 1666. In 1676, he was made a prebendary in St. Paul's; and being elected a F. R. S. presented a Roman urn to the society. About 1697, he gave to the new library of Trinity college, in Cambridge, a great number of Arabic MSS.; and in 1697 was admitted dean of York. He died in that city in 1702; and was interred in the cathedral, where a monument was erected to his memory. He was a great historian, one of the best Greek scholars of his age, and corresponded with the most learned men at home and abroad. He published, 1. *Historiæ Poetiæ Antiqui Scriptores*, 8vo. 2. *Opuscula Mythologica, Ethica et Physica*, in Greek and Latin, 8vo. 3. *Herodoti Historia*, in folio. 4. *Historiæ Anglicanæ Scriptores Quinque*, in folio. 5. *Historiæ Britannicæ, Saxonice, Anglo-Danicæ, Scriptores Quindecim*, in folio. 6. *Rhetores Selecti*, &c.

GALE, in sea-language, a term of various import. When the

wind blows not so hard but that a ship may carry her top-sails a-trip, (that is, hoisted up to the highest,) they say it is a loom gale. When it blows very strong, it is a stiff, strong, or fresh gale.

GALE. When two ships are near one another at sea, and there being but little wind blowing, one of them finds more of it than the other, they say that the one ship gales away from the other.

GALEA, in antiquity, a light casque, head-piece, or morrion, which came down to the shoulders, commonly of brass.

GALEASSE, a large low-built vessel, using both sails and oars, and the largest of all the vessels that make use of the latter. It may carry twenty guns, and has a stern capable of lodging a great number of marines. It has three masts, which are never to be lowered or taken down.

GALEGA, in botany, a genus of the decandria order, and diadelphia class of plants; natural order, Papilionaceæ. Calyx composed of subulated nearly equal dents or segments; legume has oblique striz, and seeds lying between them. It has nineteen species.

GALEN, **CLAUDIUS**, prince of the Greek physicians after Hippocrates, was born at Pergamus, in Asia Minor, A. D. 131. His father being possessed of a fortune, and well versed in philosophy, astronomy, geometry, and architecture, instructed his son in the first rudiments of learning, and afterwards procured him the greatest masters of the age. Galen, having finished his studies, chose physic for his profession, studied the works of Hippocrates, and at length resolved to travel, to converse with the most able physicians in all parts, and to take every opportunity of inspecting on the spot the plants and drugs of the countries through which he passed. With this view he went to Alexandria, where he staid some years; thence he travelled through Cilicia, Palestine, Crete, Cyprus, Lemnos, and the Lower Tyria; in which last places he obtained a thorough insight into the nature of the Lemnian earth, and the opobalsamum; after which he returned home by Alexandria. Galen had been four years at Pergamus, where his practice was attended with extraordinary applause, when some commotions induced him to go to Rome, where he resolved to settle: but the proofs he gave of his superior skill, added to the respect shewn him by several persons of very high rank, created him so many enemies among his brethren of the faculty, that he was obliged to quit Rome, after having resided there four or five years. He had not long returned to Pergamus, when he was recalled by the emperors Aurelius and Verus. After their death, he retired to his native country; where he died, about A. D. 200. He wrote in Greek; and is said to have composed 200 volumes, which were unhappily burnt in the temple of Peace. The best editions of those that remain, are, those printed at Basil in 1538, in five vols. and at Venice in 1625, in seven. Galen was of a weak and delicate constitution, as he himself asserts; but he nevertheless, by his temperance and skill in physic, arrived to a great age. One of his rules was, always to rise from table with some degree of appetite. He is justly considered as the greatest physician of antiquity, next to Hippocrates; and he performed such surprising cures, that he was accused of magic.

GALENIA, in botany, a genus of the digynia order, and octandria class of plants; natural order, Succulentæ. Calyx trifid; no corolla; capsule roundish, dispermous. It has two species.

GALENIC, or **GALENICAL**, in medicine, is applied to that manner of considering and treating diseases, founded on the principles of Galen, or introduced by Galen.

GALENICAL, is more frequently used as contradistinguished from chemical. The distinction of galenical and chemical was occasioned by a division of the practitioners of medicine into two sects, Galenists and Chemists, on the introduction of chemistry into medicine. The chemists, arrogating to themselves every kind of merit and ability, stirred up an opposition to their pretensions, founded on the invariable adherence of the other party to the ancient practice.

GALENICAL MEDICINES, are those which are formed by the easier preparations of herbs, roots, &c. by infusion, decoction, &c. and by combining and multiplying ingredients; while those of chemistry draw their more intimate and remote virtues by means of fire and elaborate preparations, as calcination, digestion, fermentation, &c.

GALENISTS, a denomination given to such physicians as practise, prescribe, or write, on the Galenical principles. They stand opposed to the chemists.

GALENISTS, or **GALENITES**, in church-history, a branch of Mennonites or Anabaptists, who take in several of the opinions of the Socinians, or rather Arians, touching the divinity of our Saviour.

GALEOPSIS, in botany, a genus of the gymnospermia order, and didynamia class of plants; natural order, Verticillatæ. Corolla, upper lip a little crenated or arched; the under lip bidentate, two teeth above. There are four species.

GALERICULUM, in Roman antiquity, a cap worn both by men and women, consisting of a skin, so neatly dressed with human hair, that the artificial covering could scarcely be distinguished from the natural.

GALFALLY, a town of Ireland, in Tipperary, 32 miles S. E. of Limerick.

GALICIA, a province of Spain, bounded on the N. and W. by the ocean, on the S. by Portugal, and on the E. by Asturias and Leon. The air is temperate along the coast, but in other places, cold and moist.

GALICIA, or **GUADALAXARA**, a country of Mexico, containing seven provinces. It has mines of silver and copper, and abounds with corn. The climate is temperate. Guadalaxara is the capital.

GALICIA, the modern name given to a large country in the S. of Poland, which was seized on by the late emperor Joseph II, and annexed to the Austrian dominions. It comprehends a part of Red Russia and the palatinate of Lemberg; and is separated from Hungary by the Carpathian mountains.

GALILEE, in ancient geography, a province of Judea, bounded by mount Lebanon on the N. by the Jordan and the sea of Galilee on the E. by the Chison on the S. and by the Mediterranean on the W. It was the scene of many of our Saviour's miracles; but the bounds of the country are not now well known, nor the places where many of the towns stood. It belongs to the Turks.

GALILEANS, a sect of the Jews. Their founder was one Judas, a native of Galilee, who, esteeming it an indignity for the Jews to pay tribute to strangers, raised up his countrymen against the edict of Augustus, which had ordered a taxation of all the subjects of the Roman empire. They insisted that God alone should be owned as Lord. In other respects they were of the opinion of the Pharisees; but, as they judged it unlawful to pray for infidel princes, they separated from the rest of the Jews, and performed their sacrifices apart. As our Saviour was supposed to be a native of Galilee, and his apostles were mostly Galileans, they were suspected to be of this sect; and it was on this principle, as St. Jerome observes, that the Pharisees laid a snare for him; by asking, whether it was lawful to give tribute to Cæsar; that in case he denied it, they might have an occasion of accusing him.

GALILEO, **GALILEI**, the famous mathematician and astronomer, was the son of a Florentine nobleman, and born in 1564. He had from his infancy a strong inclination to philosophy and mathematics; and made prodigious progress in these sciences. In 1592, he was chosen professor of mathematics at Padua. In 1609, having heard that Jansen had invented a glass by which objects at a distance were rendered as visible as if near, he turned his attention to the subject, and constructed a telescope, by means of which he discovered various phenomena in the heavens, not before heard of. In 1611, Cosmo II, grand duke of Tuscany, sent for him to Pisa, where he made him professor of mathematics, with a handsome salary; and soon after inviting him to Florence, gave him the office and title of principal philosopher and mathematician to his highness. He had been but a few years at Florence, before he was convinced, that Aristotle's doctrine, however ill-grounded, was held too sacred to be called in question. Having observed some solar spots in 1612, he printed that discovery in 1613, at Rome; in which, and in some other pieces, he ventured to assert the truth of the Copernican system, and brought several new arguments to confirm it. For these he was cited before the inquisition; and, after some months' imprisonment, was released upon a simple promise, that he would renounce his heretical opinions, and not defend them by word or writing. But having afterwards, in 1632, published at Florence his "Dialogues of the two greatest Systems of the World, the Ptolemaic and Copernican," he was again cited before the inquisition, and committed to the prison of that dreadful court at Rome. On June 22, N. S. 1632, the congregation convened; and in his presence pronounced sen-

tence against him and his books, obliging him to abjure his errors in the most solemn manner; committed him to the prison of their office during pleasure; and enjoined him, as a saving penance, for three years, to repeat once a-week the seven penitential psalms: reserving to themselves, however, the power of moderating, changing, or taking away altogether, or in part, the above-mentioned punishment and penance. On this sentence, he was detained a prisoner till 1634: and his *Dialogues of the System of the World* were burnt at Rome. He lived ten years after this, seven of which were employed in making still further discoveries with his telescope. But by the continual application to that instrument, added to the damage he received in his sight from the nocturnal air, his eyes grew gradually weaker, till he became totally blind in 1639. He bore this calamity with patience and resignation, worthy of a great philosopher. The loss neither broke his spirit, nor hindered the course of his studies. He supplied the defect by constant meditation: whereby he prepared a large quantity of materials, and began to dictate his own conceptions; when, wasting away by degrees, he expired at Arcetti near Florence, in January, 1642, N. S. aged 78. His discoveries and writings have rendered essential service to philosophy. From the time of Archimedes, as M. Leibnitz observed, there had been nothing done in mechanical geometry, till Galileo, who possessing an excellent judgement, and great skill in the most abstruse points of geometry, first extended the boundaries of that science, and began to reduce the resistance of solid bodies to its laws. As observed by Dr. Hutton, "He made the evidence of the Copernican system more sensible, when he shewed from the phases of Venus, like to the monthly phases of the moon, that Venus actually revolves about the sun. He proved the revolution of the sun on his axis, from his spots; and thence the diurnal rotation of the earth became more credible. The four satellites that attended Jupiter, in his revolution about the sun, represented, in Jupiter's less system, a just image of the great Solar System, and rendered it more easy to conceive how the moon might attend the earth, as a satellite, in her annual revolution. By discovering hills and cavities in the moon, and spots in the sun constantly varying, he shewed that there was not so great a difference between celestial and sublunary bodies as the philosophers had vainly imagined. "He rendered no less service to science by treating, in a clear and geometrical manner, the doctrine of motion, which has been justly called the key of nature. The rational part of mechanics had been so much neglected, that scarcely any improvement was made in it for almost 2000 years; but Galileo has given us fully the theory of equable motions, and of such as are uniformly accelerated or retarded, and of these two compounded together. He first demonstrated, that the spaces described by heavy bodies from the beginning of their descent, are as the squares of the times; and that a body, projected in any direction that is not perpendicular to the horizon, describes a parabola. These were the beginnings of the doctrine of the motion of heavy bodies, which has been since carried to so great a height by Sir Isaac Newton. In geometry, he invented the cycloid, or trochoid, though the properties of it were afterwards chiefly demonstrated by his pupil Torricelli. He invented the simple pendulum, and made use of it in his astronomical experiments: he had also thoughts of applying it to clocks, but did not execute that design. The glory of that invention was reserved for his son Vincenzo, who made the experiment at Venice in 1649; and Huygens afterwards carried the invention to perfection. Of Galileo's invention also was the machine with which the Venetians render their laguna fluid and navigable. He also discovered the gravity of the air, and endeavoured to compare it with that of water; and opened several other inquiries in natural philosophy. He was not esteemed and followed by philosophers only; but was honoured by persons of the greatest distinction of all nations. Galileo had scholars worthy of so great a master, by whom the gravitation of the atmosphere was fully established, and its varying pressure accurately and conveniently measured, by the column of quicksilver of equal weight sustained by it in the barometrical tube. The elasticity of the air, by which it perpetually endeavours to expand itself, and while it admits of condensation, resists in proportion to its density, was a phenomenon of a new kind, (the common fluids having no such property), and of the utmost importance to philosophy. These principles opened a vast field of new and useful knowledge, and explained a

great variety of phenomena, which had been accounted for in an absurd manner before that time. It seemed as if the air, the fluid in which men lived from the beginning, had been then first discovered. Philosophers were every where busy, enquiring into the various properties and their effects; and valuable discoveries rewarded their industry. Of the great number who distinguished themselves on this occasion, we cannot but mention Torricelli and Viviani, in Italy; Pascal, in France; Otto Guricke, in Germany; and Boyle, in England." Galileo wrote a number of treatises, of which the principal published during his life-time were, "A Treatise on Mechanics," "On the Balance," and "Dialogues on the Solar System;" "The Operations of the Compass, geometrical and military," 1606; "A Discourse, addressed to the Most Serene Cosmo II. Grand Duke of Tuscany, concerning the Swimming of Bodies upon, and their Submersion in, Water," 1612; "Nuncius Sidereus," 1610, of which a "Continuation," or "An Essay on the History of Galileo's last Observations on Saturn, Mars, Venus, and the Sun, &c." was afterwards collected from letters between Galileo and his correspondents; "A Letter Concerning the Trepidation of the Moon, lately discovered, inscribed to Alphonso Antonini, with Antonini's Answer," 1638; "A Discourse of the Solar Spots, &c. with Predictions and Ephemerides of the Medicean Planets," 1613; the famous Italian piece, entitled, "Il Saggiatore," written in defence of Guiducci's "Discourse on Comets," and containing a complete account of the physiology and astronomy of our author, printed in 1623; "A Letter to Prince Leopold of Tuscany, Examining the fiftieth chapter of Licetus's *Letheosporos*;" "A Letter to Christopher Greinbergerus, Concerning the Montuosity of the Moon," 1611; "Mathematical Discourses and Demonstrations Concerning two new Sciences, Relating to Mechanics and Local Motions, together with an Appendix Concerning the Centre of Gravity in some Solids, 1638, &c. The preceding articles, together with some other treatises, written either by Galileo, or by some of his disciples, in defence of his doctrines and observations, were collected and published by Menolessi, in 1656, under the title of "L'Opere de Galileo Galilei Lynceo, nobile Fiorentino," &c. in two volumes quarto. Several of these pieces were translated into English, and published by Thomas Salisbry, in his "Mathematical Collections," in two vols. folio. A volume also of his "Letters" to several learned men, and solutions of a variety of problems, were published at Bologna, in quarto. His last disciple, Vincenzo Viviani, who proved a very eminent mathematician, methodised a piece of his master's, and published it under the title of "Quinto Libro de gli Elementi d'Euclid," &c. 1674, quarto; and he also published some other pieces of Galileo, including extracts from his "Letters to a Learned Frenchman," in which the author gives an account of the works which he intended to have published, and an extract of a letter to John Camillo, a mathematician of Naples, concerning the angle of contact. Many other of Galileo's writings were unfortunately lost to the world, owing to the superstition of those to whom they were left.

GALIPAGO ISLES, several uninhabited islands in the South Sea, on both sides of the equator, near Terra Firma, belonging to Spain. Lon. between 83. 40. and 89. 30. W. Lat. from 3° to 5° S.

GALITSCH, a town of Russia, in Kostrom, 56 miles E. N. E. of Kostrom.

GALIUM, in botany, a genus of the monogynia order, and tetrandria class of plants; natural order, Stellata. Corolla monopetalous, plain; seeds two, roundish. There are forty-eight species.

G. APERINE, **CLIVERS**, or **GOOSE-GRASS**, has a square, very rough, jointed, weak stem, two, three, or four feet long, and adhesive: the branches are opposite; the joints hairy at the base: the seeds are rough; flowers white, small, few, on slender footstalks on the tops of the branches. It is common in fields by the sides of hedges, &c. The expressed juice of this plant taken internally, and the bruised leaves applied by way of poultice, are said to have been used with success as a cure for the cancer.

G. VERUM, the **YELLOW LADY'S BED-STRAW**, has a firm, erect, brown, square, stem; the leaves generally eight in each whirl, linear, pointed, brittle, and often reflex; branches short, generally two from each joint, terminating in spikes of small yellow flowers. It grows commonly in dry ground, and on roadsides.

sides. The flowers coagulate boiling milk; and the best Cheshire cheese is said to be prepared with them. The roots dye a red not inferior to madder. In the Edinburgh Medical Commentaries we have accounts of some violent scorbutic complaints being cured by the juice of this plant.

GALL, in the animal economy, the same with bile. See **BILE** and **ANATOMY**.

GALL, in natural history, signifies any protuberance, or tumor, produced by the punctures of insects on plants and trees of various kinds; but especially the quercus, or oak; cistus, or rock-rose; glechoma hederacea, or ground-ivy; salix, or willow; hieraceum, or hawkweed; salvia, or clary; veronica, or speedwell, &c. Insects deposit their eggs in the leaves or tender branches of plants, the juice of which exudes, and in a short time forms tumors around the punctures or holes. The external coat of this excrescence is dried by the air, and during the winter affords a secure shelter to the inclosed insect, while the soft inner pulp furnishes it with sustenance till the spring approaches, when the fly perforates the shell or rind, and departs. The best of these galls are those found on oak-trees, and which are thence called oak-galls; they are deposited by the cynips quercus gemma, or oak-bud-cynips. See **CYNIPS**. A small portion of galls infused in a weak solution of vitriol in water, imparts to it a purple or violet tint; which, after the whole of the colouring matter is extracted, becomes perfectly black. Considerable quantities of this drug are used in Britain, for the making of ink.

GALL, **ST.** or **ST. GALEN**, a considerable town in Switzerland, in the Upper Thurgau, 37 miles N. E. of Zurich.

GALLA, a nation of Ethiopia, originally dwelling, as Mr. Bruce supposes, under the line, and exercising the profession of shepherds, which they still continue to do. For many years, he says, they have been constantly migrating northwards, though the cause of this migration is not known. At first they had no horses; the reason of which was, that the country they came from did not allow these animals to breed; but as they proceeded northward and conquered some of the Abyssinian provinces, they soon furnished themselves with such numbers, that they are now almost entirely cavalry, and make little account of infantry in their armies.

GALLA, a town of Arabia, 24 miles S. E. of Taas.

GALLAM, a kingdom of Africa.

GALLAM, the capital of the above kingdom, is seated on the Senegal. Lon. 9. 55. W. Lat. 14. 25. N.

GALLE, or **PORT GALLE**, a sea-port town and fort on the S. W. coast of Ceylon.

GALLEON, [*galion*, Fr.] a large ship with four or sometimes five decks, employed in the Spanish West India trade. The Spaniards send annually two fleets; the one for Mexico, which they call the flota; and the other for Peru, which they call the galleons. By a general regulation made in Spain, it has been established; that there should be twelve men of war and five tenders annually fitted out for the armada or galleons; eight ships of 600 tons burden each, and three tenders, one of 100 tons, for the island Margarita, and two of 80 each, to follow the armada; for the New Spain fleet, two ships of 600 tons each, and two tenders of 80 each; and for the Honduras fleet, two ships of 500 tons each: and in case no fleet happened to sail any years, three galleons and a tender should be sent to New Spain for the plate. They sail from Cadiz in January, that they may arrive at Porto Bello in April; where, the fair being over, they may take aboard the plate, and be at Havannah with it about the middle of June; where they are joined by the flota that they may return to Spain with the greater safety.

GALLEOT. See **GALLIOT**.

GALLERY, in gardening, an ornament made with trees of different kinds. Galleries are very common in the French gardens, but are seldom introduced into the British ones, especially since the taste for clipping trees has been exploded.

GALLERY, in a ship, that beautiful frame, which is made in the form of a balcony, at the stern of a ship without board; into which there is a passage out of the admiral's or captain's cabin, and is designed for the ornament of the ship.

GALLERY, in fortification, a covered walk across the ditch of a town, made of strong beams covered with planks, and loaded with earth: sometimes it is covered with raw hides, to defend it from the artificial fires of the besieged.

VOL. II.—NO. 91.

GALLERY OF A MINE is a narrow passage or branch of a mine carried on under ground to a work designed to be blown up.

GALLEYS, low flat-built vessels, furnished with one deck, and navigated with sails and oars. The largest sort are employed only by the Venetians. They are commonly 162 feet long above, and 133 feet by the keel: 32 feet wide, with 23 feet length of stern-post. They are furnished with three masts, and 32 banks of oars; every bank containing two oars and every oar being managed by six or seven slaves, who are usually chained thereto. In the fore-part they have three little batteries of cannon, of which the lowest is of two 36 pounders, the second of two 24 pounders, and the uppermost of two 2 pounders: three 18 pounders are also planted on each quarter. The complement of men for one of these galleys is 1000 or 1200. They are esteemed very convenient for bombarding or making a descent upon an enemy's coast, as drawing but little water; and having by their oars frequently the advantage of a ship of war, in light winds or calms, by cannonading the latter near the surface of the water; by scouring her whole length with their shot, and at the same time keeping, on her quarter or bow, so as to be out of the direction of her cannon. Galley is the name also of an open boat, rowing six or eight oars, and used on the Thames by Custom-house-officers, press-gangs, and also for pleasure. The same word denotes the kitchen of a ship of war, or the place where the grates are put up, fires lighted, and the victuals generally dressed.

GALLEY-SLAVE, a person condemned, in France, to work at the oar on board a galley, being chained to the deck.

GALLEY-WORM, in zoology. See **IVULUS**.

GALL FLY, in entomology. See **CYNIPS**.

GALLI, in antiquity, a name given to the priests of Cybele, from the river Gallus in Phrygia. They were Eunuchs and Phrygians, and in their solemn processions danced, bawled, drummed, cut and slashed themselves, playing upon timbrels, pipes, cymbals, &c. and driving about an ass loaded with the sacred trumpery of their goddess.

GALLI, five small desolate islands on the coast of the Principato Citra of Naples. They are supposed to be the Syrenusæ, or islands once inhabited by the Syrens, which Ulysses passed with so much caution and hazard.

GALLIA, in ancient geography, a large country of Europe, called Galatia by the Greeks. The inhabitants were called Galli, Celtæ, Celtiberi, and Celtoscythæ. Ancient Gaul was divided into four different parts by the Romans, called Gallia Belgica, Narbonensis, Aquitania, and Celtica. Besides these grand divisions there is often mention made of Gallia Cisalpina or Citerior, and Transalpina or Ulterior, which last comprehended the whole of Gaul, properly so called, as possessed by the ancient Gauls. The inhabitants were great warriors, and overcame the Roman armies, took the city of Rome, and invaded Greece in different ages.

1. **GALLIA AQUITANICA** contained the late provinces of Poitou, Saintonge, Guienne, Berry, Limosin, Gascony, Auvergne, &c. and was situated between the Garumna, the Pyrenean mountains, and the ocean.

2. **GALLIA BELGICA** was the largest province, bounded by Germany, Gallia Narbonensis, and the German ocean; and contained the modern countries of Alsace, Lorraine, Picardy, with part of the Low Countries, of Champagne, and of the isle of France.

3. **GALLIA CELTICA**, or **LUGDUNENSIS**, was bounded by Belgium, Gallia Narbonensis, the Alps, and the ocean. It contained the countries heretofore known by the names of Lyonnois, Touraine, Franche Comté, Senenois, Switzerland, and part of Normandy. It was also called Comata, because the people suffered their hair to grow to an uncommon length.

4. **GALLIA CISALPINA**, or **CITERIOR**. By these names the Romans understood that part of Gaul which lies in Italy, on this side of the Alps, in regard to the inhabitants of Rome. They also stiled it Gallia Togata, because the Roman gowns called togæ were worn by the people.

5. **GALLIA CISPADANA** in ancient geography, was applied to a part of Italy conquered by some of the Gauls; and meant the country on this side of the Po, with respect to Rome. See **CISPADANA**.

6 T

6. **GALLIA**

6. *GALLIA NARBONENSIS*, which contained the provinces lately called Languedoc, Provence, Dauphiné, and Savoy, was bounded by the Alps and Pyrenean mountains, by Aquitania, Belgium, and the Mediterranean. *Gallia Narbonensis* was called *Braccata*, on account of the peculiar covering of the inhabitants for their thighs.

7. *GALLIA TRANSALPINA*, or *ULTERIOR*, was the name given by the Romans to that part of Gaul, which lay beyond the Alps, in regard to Rome.

8. *GALLIA TRANSPADANA*, was the name given to that part of Italy, conquered by the Gauls, which lay beyond the Po, in respect of Rome.

GALLIARD, or *GALLIARDA*, a sort of dance anciently in great request, consisting of very different motions and actions, sometimes proceeding terra a terra, or smoothly along, sometimes capering, sometimes along the room, and sometimes across.

GALLIAMBIC VERSE, in ancient poetry, a verse consisting of six feet, viz. an anapaest or spondee; an iambus, or an anapaest, or a tribrach; an iambus; a dactyl; an anapaest.

GALLIC ACID, in chemistry, an acid obtained from the nut-gall. In an infusion of galls made with cold water, a sediment is formed which on examination is found to have a crystalline form and an acid taste. By letting an infusion of galls remain a long time exposed to the air, and removing now and then the mouldy skin which formed on its surface, a large quantity of this sediment was obtained; which beingedulcorated with cold water, redissolved in hot water, filtrated and evaporated very slowly, yielded an acid salt in crystals as fine as sand. Mr. Davy obtained the gallic acid in a state of considerable purity by the following method: Boil for some time a mixture of carbonate of barytes and infusion of nut-galls. A bluish green liquid is obtained, which consists of a solution of gallic acid and barytes. Filter and saturate with diluted sulphuric acid. Sulphate of barytes is deposited in the state of an insoluble powder, and a colourless solution of gallic acid remains behind. Gallic acid, when pure, is in the form of transparent plates or octahedrons. Its taste is acid, and somewhat astringent; and when heated it has a peculiar and rather unpleasant aromatic odour. It is soluble in one and a half parts of boiling water, and in twelve parts of cold water. When this solution is heated, the acid undergoes a very speedy decomposition. Alcohol dissolves one-fourth of its weight of this acid at the temperature of the atmosphere. When boiling hot, it dissolves a quantity equal to its own weight. It is insoluble in ether. When exposed to the action of heat, it is sublimed without alteration: but a strong heat decomposes it in part, and converts it into an acid water, carbureted hydrogen gas, carbonic acid gas, oil, and charcoal. It combines with alkaline bodies, making with them compounds called gallates. It occasions a precipitate when poured into solutions of glucina, yttria, and zircon, in acids, which distinguishes these from the other earths, none of which are precipitated from their solutions by gallic acid. Upon the metallic solutions gallic acid acts with great energy, changing the colour, and producing precipitates in many of them. Hence it is frequently used as a re-agent to detect the presence of metallic bodies. It is composed of oxygen, carbon, and hydrogen, but the proportions of each have not been accurately ascertained.

GALLINÆ, in ornithology, the fifth order of birds: the upper mandible is channelled, extending with a margin above the lower, and a little bowed; the nostrils are covered with a cartilaginous membrane; they live upon grain, dust themselves, make an artless nest, and lay many eggs. Under this order are comprehended the peacock, pheasant, turkey, the common dunghill-cock, partridge, grouse, dodo, curisspa, &c.

GALLINARA, an island on the coast of Genoa, 10 miles S. of Finale.

GALLING OF A HORSE'S BACK, a disorder, occasioned by heat, and the chafing or pinching of the saddle. To prevent it, some take a hind's skin well garnished with hair, and fit it neatly under the pannel of the saddle, so that the hairy side may be next the horse. When a horse's back is galled upon a journey, take out a little of the stuffing of the pannel over the swelling, and sew a piece of soft white leather on the inside of the pannel; anoint the part with salt butter, and every evening wipe it clean, rubbing it till it grow soft, anointing it again with butter, or, for

want of that, with grease: wash the swelling or hurt every evening with cold water and soap; and strew it with salt, which should be left on till the horse be saddled in the morning.

GALLIOPOLIS, or *GALLIPOLIS*, a post-town of the United States, in the North Western Territory, seated on the Ohio, 140 miles E. of Columbia, and 559 S. W. of Philadelphia.

GALLIOT, [*galliotte*, French,] a small galley designed only for chase, carrying only one mast, and two or three patteringoes; it can both sail and row, and has sixteen or twenty oars. All the seamen on board are soldiers, and each has a musket by him on quitting his oar.

GALLIPOLI, a sea-port town of Naples, in the province of Otranto, 21 miles W. of Otranto.

GALLIPOLI, a sea-port town of European Turkey, in the province of Romania, seated at the mouth of the sea of Marmora. Lon. 26. 59. E. Lat. 40. 24. N.

GALLIUM, in botany. See *GALIUM*.

GALLO, an island of the South Sea, near the coast of Peru. Lon. 88. 0. W. Lat. 2. 30. N.

GALLO-GRÆCIA, a country of Asia Minor, near Bithynia and Cappadocia.

GALLON, a measure of capacity both for dry and liquid things, but differs according to the quality of the thing measured: For instance, the wine-gallon contains 231 cubic inches, and holds 8 lb. avoirdupois of pure water; the beer and ale gallon contains 281 solid inches, and holds 10 lb. 3½ ounces avoirdupois of water; and the gallon for corn, meal, &c. 272½ cubic inches, and holds 9 lb. 13 ounces of pure water.

GALLOON, in commerce, a narrow thick kind of ferret, or lace, used to edge or border cloaths, sometimes made of wool, and at others of gold or silver.

GALLOP, [*galoper*, Fr. from *καλπαζειν*,] in the manege, a motion of a horse that runs at full speed, in which making a kind of leap forwards, he lifts both his fore-legs almost at the same time; when these are in the air, just upon the point of touching the ground, he lifts both his hind legs almost at once.

GALLOPER, in artillery, is the name of a carriage, which serves for a pound and a half-gun. This carriage has shafts so as to be drawn without a limber, and is thought by some to be more convenient and preferable to other field-carriages; and it may likewise serve for our light three and six pounders.

GALLOWAY, in geography, a county of Scotland, which is divided into two districts; the western, called the Upper, and the eastern, Lower.

1. *GALLOWAY, LOWER*, or the Stewartry of Kirkcudbright.

2. *GALLOWAY, UPPER*, or the county of Wigton.

GALLOWAY, MULL OF, the south cape or promontory of all Scotland, in the county of Galloway, on the Irish sea.

GALLOWES, [*gealgo*, Sax. *galge*, Dut. which some derive from גלגל, high, others from *gallu*, Welsh, power: but it is probably derived like *gallow*, to fright, from *agalwan*, the gallows, being the great object of legal terror,] a beam laid over two posts, on which malefactors are hanged.

GALLOWES, among our ancestors, was called *furca*, fork; a name by which it is still denominated abroad, particularly in France and Italy. In this latter country, the reason of the name still subsists; the gallows being a real fork drove into the ground, across the legs whereof is laid a beam, to which the rope is tied.

GALLY, in printing, a frame into which the compositor empties the lines out of his composing-stick, and in which he ties up the page when it is completed. The gally is formed of an oblong square board, with a ledge on three sides, and a groove to admit a false-bottom, called a gally-slice.

GALOPINA, in botany, a genus of the tetrandria digynia class and order. Calyx none; corolla four-cleft; seeds two, naked. There is one species, viz. *G. circeoides*, a native of the Cape of Good Hope.

GALWAY, a county of Ireland, in the province of Connaught, bounded by Clare, Tipperary, King's County, Roscommon, and the sea.

GALWAY, the capital of the above county, 96 miles W. of Dublin. Lon. 9° W. Lat. 53° 18' N.

GALVANI, LEWIS, an eminent physiologist, born at Bologna.

logna in 1737. From his youth he was strongly attached to the Roman Catholic religion. He studied medicine under Beccari, Jacconi, Galli, and professor Galeazzi, whose daughter he married. He was created lecturer on anatomy in the university of Bologna in 1762. He soon acquired a very high reputation as an anatomist and physiologist, and great crowds attended his lectures. His extensive knowledge, and industry in making experiments led to a discovery, from which he had the honour of giving his name to a new subject of philosophical inquiry. Happening to have some frogs lying on the table of his laboratory, skinned for the purpose of making soup as a restorative for his wife, who was in a declining state of health, one of his assistants chanced to bring the point of a scalpel near the crural nerves of a frog, which was near the conductor. Instantly the muscles of the limb were agitated with strong convulsions. This was observed by Madame Galvani, a woman of quick understanding, and a scientific turn, and she immediately mentioned it to her husband. He repeated

the experiment; and soon found that the convulsion only took place when a spark was drawn from the conductor, at the time the scalpel was in contact with the nerve. This induced him to go through a series of experiments, which have laid the foundation of Galvanism. Galvani was a man of an amiable character in private life, and possessed of great sensibility. The death of his wife in 1790, threw him into a profound melancholy. On refusing to take the civic oath exacted by the new constitution of the Cisalpine Republic, he incurred the deprivation of his posts and dignities. A prey to melancholy, and reduced almost to indigence, he retired to the house of his brother James, a man of very respectable character, where he indulged his grief. The republican governors, probably ashamed of their conduct towards such a man, passed a decree for his restoration to his professional chair and its emoluments; but it was then too late. He died in 1798, on November 5, aged sixty, being much lamented by his friends and the public.

GALVANISM.

GALVANISM, (so called from Dr. Galvani, the discoverer,) that branch of philosophy which investigates and explains the phenomena arising from the action or influence of certain bodies so disposed as to form a continued chain, or circle of communication with each other. Dr. Galvani was led to the discoveries, which gave rise to this department of science, by an incidental circumstance, mentioned in the last article, which shewed the effects of a small quantity of electricity on the nerves and muscles of a frog. From a series of experiments on this subject, principally performed on dead frogs, he found that a small quantity of electricity is capable of bringing the muscles into action, even after the animal has been dead a considerable time. He also found that independent of any apparent electricity, the same motions may be produced in the dead animal, or even in a detached limb, merely by making a communication between the nerves and the muscles, with substances that are conductors of electricity. If the circuit of communication consists of non-conductors of electricity, as glass, sealing-wax, and the like, no motion will take place. Similar experiments were also successfully instituted upon other animals; and as the power seemed to be inherent in the animal parts, those experiments, or the power which produces the motion of the muscles in those experiments, were denominated animal electricity. But it being now fully ascertained, that by the mere contact of metallic and other conducting substances, some electricity is generated, it is evident that the muscular motions in the above-mentioned experiments are produced by that electricity. Dr. Galvani, in making his experiments, used to skin the legs of a frog recently dead, and to leave them attached to a small part of the spine, but separated from the rest of the body. Any other limb may be prepared in a similar manner; viz. the limb is deprived of its integuments, and the nerve which belongs to it is partly laid bare. If the limbs thus prepared, for instance the legs of a frog, are situated so that a little electricity may pass through them, be it by the immediate contact of an electrified body, or by the action of electric atmospheres (as when the preparation is placed within a certain distance of an electrical machine, and a spark is taken from the prime conductor); the prepared legs will be instantly affected with a kind of spasmodic contraction, sometimes so strong as to jump a considerable way. When the electricity is caused to pass through the prepared frog by the immediate contact of the electrified body, a much smaller quantity of it is sufficient to occasion the movements, than when it is made to pass from one conductor to another, at a certain distance from the prepared animal. The movements are much stronger when the electricity is caused to pass through a nerve to the muscle or muscles, than through any other part. The sensibility of the prepared animal is greatest at first, but it diminishes by degrees till it

vanishes entirely. Animals with cold blood, and especially frogs, retain that sensibility for several hours, sometimes even for a day or two. With other animals the sensibility does not last long after death, and sometimes not above a few minutes. The like movements may be produced in the prepared animal without the aid of any apparent electricity. In an animal recently dead, detach one end of a nerve from the surrounding parts, taking care to cut it not too near its insertion into the muscle; remove the integuments from over the muscles which depend on that nerve; take a piece of metal, as a wire, and touch the nerve with one extremity of it, and the muscles with its other extremity; on doing which you will find that the prepared limbs move in the same manner as when some electricity is passed through them. This, however, is not the most effectual way of forming the communication; yet it will generally succeed, and the experiment will answer whether the preparation be laid upon conductors or upon electrics. If the communication between the nerve and the muscle be formed by the interposition of non conductors of electricity, such as glass, sealing-wax, &c. then no movements will take place. When the application of the metal or metals is continued upon the parts, the contractions will cease after a certain time, and on removing the metal, seldom, if ever, any contraction is observed. The conducting communication between the muscle and the nerve may consist of one or more pieces, and of the same, or much better, of different bodies connected together, as metals, water, a number of persons, and even wood. But it must be observed, that the various bodies, which form this circuit, must be placed in full and perfect contact with each other, which is done by pressure, or by the interposition of water, &c. The less perfect conductors will answer only at first, when the prepared animal is vigorous; but when the power begins to diminish, then the more perfect conductors will only answer, and even these will produce various effects. The most effectual way that has hitherto been discovered of producing those movements in prepared animal parts is by the application of two metals, of which silver and zinc seem upon the whole to be best, though silver and tin, or copper and zinc, and other combinations, are not much inferior to them. If part of the nerve proceeding from a prepared limb is wrapped up in a bit of tin-foil, or only laid upon zinc, and a piece of silver laid with one end upon the bare muscle, and with the other upon the above-mentioned tin or zinc, the motion of the prepared limb will be very vigorous. The two metals may be placed not in contact with the preparation, but in any other part of the circuit, which may be completed by means of other conductors, as water, &c. The best preparation for this experiment is made in the following manner. Separate with a pair of scissors the head and upper extremities of a frog from the rest of the body. Open

the integuments and muscles of the abdomen, and remove the entrails, by which means you will lay bare the crural nerves. Then pass one blade of the scissors under the nerve, and cut off the spine with the flesh close to the thighs, by which means the legs will remain attached to the spine by the nerves alone. This done, leave a small bit only of the spine attached to the crural nerves, and cut off all the rest. Thus you will have the lower limbs G, H, fig. 1, Plate LXXIX, of the frog adhering to the bite of spine A B, by means of the crural nerves C, D. These legs must be flayed in order to lay bare the muscles; and a bit of tin-foil should be wrapped round the spine A B. With this preparation the experiment may be performed in various ways, but the two which follow are the best. Hold the preparation by the extremity of one leg, the other leg hanging down, with the armed bundle of nerves and spine lying upon it. In this situation interpose a piece of silver, as a half-crown, between the lower thigh and the nerves, so that it may touch the former with one surface, and the metallic coating of the latter with the other surface, or with its edge; and you will find that the hanging leg will vibrate very powerfully, sometimes so far as to strike against the hand of the operator, which holds the other leg. Otherwise, place two wine-glasses, both full of water, contiguous to each other, but not actually touching. Put the thighs and legs of the preparation in the water of one glass, and laying the nerves over the edges of the two glasses, let the bit of spine with its armour (viz. tin-foil) touch the water of the other glass. Things being thus prepared, if you form the communication between the waters of the two glasses, by means of silver, or put the fingers of one hand into the water of the glass that contains the legs, and holding a piece of silver in the other, you touch the coating of the nerves with it, you will find that the prepared legs move so powerfully as sometimes to jump fairly out of the glass. Different metals, properly disposed were soon found to affect several of the senses in a remarkable manner. Let a man lay a piece of metal, as zinc, upon his tongue, and a piece of some other metal, as silver, under the tongue; on forming the communication between those two metals, either by bringing their outer edges in contact, or by the interposition of some other piece of metal, he will perceive a peculiar sensation, a kind of irritation, accompanied with a sort of cool and subacid taste, not exactly like, and yet not much different from, that which is produced by artificial electricity. The sensation seems to be more distinct when the metals are of the usual temperature of the tongue. The silver or gold may be applied to any other part of the mouth, to the nostrils, to the ear, or to other sensible parts of the body, whilst the zinc is applied to the tongue; and on making the communication between the two metals, the taste will be perceived upon the tongue. The effect is rather more remarkable when the tongue touches the zinc in a small part, and the silver in a great portion of its surface, than vice versa. Instead of the tongue, the two metals may also be placed in contact with the roof of the mouth, as far back as possible; and on completing the communication, the taste or irritation will be perceived. Different persons are variously affected by this application of metals; with some the sensation or taste is so slight as to be hardly perceived, whilst with others it is very strong, and even disagreeable. Some persons feel merely a pungency, and not properly a taste. In order to affect the sense of sight by means of metals, let a man in a dark place put a slip of tin-foil upon the bulb of one of his eyes, and let him put a piece of silver, as a spoon or the like, in his mouth. On completing the communication between the spoon and the tin-foil, a faint flash of white light will appear before his eyes. This experiment may be performed in a more convenient manner, by placing a piece of zinc between the upper lip and the gums, as high up as possible, and a silver piece of money upon the tongue; or else by putting a piece of silver high up in one of the nostrils, and a piece of zinc in contact with the upper part of the tongue; for in either case the flash of light will appear whenever the two metals are made to communicate, either by the immediate contact of their edges, or by the interposition of other good conductors. By continuing the contact of the two metals, the appearance of light is not continued, it being only visible at the moment of making the contact, and sometimes, though rarely, at the instant of separation: it may therefore be repeated at pleasure, by disjoining, and again connecting, the two metals. When the eyes are in a state of inflammation, the appearance of light is much stronger. When the science was advanced no farther than

the knowledge of the above-mentioned facts, it was doubtful whether the convulsions of prepared animal limbs, and the sensations which are produced by the application of metallic substances, were owing to some electrical property peculiar to the animal parts, which might perhaps be conducted through the metals from one part to the other; or to a small quantity of electricity, which might be supplied by the metals themselves. The latter supposition however was soon verified by the result of various experiments, which prove in the most convincing manner that electricity is produced by the mere contact, not only of metallic substances, but likewise of other bodies. The electricity thus produced by the mere contact of two bodies is so very small as not to be perceived without great care, and without using some of those artifices for discovering small quantities of electricity, which have been mentioned above. But the discoveries of the ingenious Mr. Volta have shewn a method of increasing that electricity to a most extraordinary degree. The action of metallic substances upon the organs of living, or of recently dead animals, has been fully manifested by the above-mentioned discoveries of Galvani and others: but, previously to those discoveries, a variety of facts, frequently asserted, imperfectly known, and often disbelieved, indicated a peculiar action arising from a combination of different metallic bodies in certain cases. It had been long asserted, that when porter (and some other liquors also) is drunk out of a pewter-pot, it has a taste different from what it has when drunk out of glass or earthenware. It has been observed, that pure mercury retains its metallic splendour during a long time; but its amalgam with any other metal is soon tarnished or oxidated. The Etruscan inscriptions, engraved upon pure lead, are preserved to this day; whereas some medals of lead and tin, of no great antiquity, are much corroded. Works of metal, whose parts are soldered together by the interposition of other metals, soon tarnish about the places where the different metals are joined. When the copper-sheeting of ships is fastened on by means of iron nails, those nails, but particularly the copper, are readily corroded about the place of contact. It had been observed that a piece of zinc might be kept in water for a considerable time, with hardly oxidating at all; but that the oxidation would soon take place if a piece of silver happened to touch the zinc, whilst standing in water. The discoveries of Galvani induced many able philosophers to repeat the experiments on this subject; among whom Volta, Aldini, Valli, and Dr's. Monro, Fowler, and Creve, particularly distinguished themselves, and fully confirmed the truth of the effects. Galvani had supposed that these phenomena were produced by the electricity of the animal conveyed between the nerves and muscles through the conductor applied. This hypothesis was successfully opposed by Volta, who made it evident, that the electricity is excited by means of the contact of the different substances, and that they do not act merely as conductors. This view of the subject led the ingenious Volta to the discovery of the pile, called the Voltaic pile, by which the Galvanic influence may be extended to almost any degree. Volta invented two forms of this instrument represented in fig. 16, and 17, and to be described in this article. Volta transmitted an account of this truly admirable discovery, to the Royal Society London, soon after it was made. Several experiments were soon made with this apparatus, by the philosophers of this country; the first of any note were performed by Messrs. Nicolson and Carlisle. Mr. Cruickshank of Woolwich, paid considerable attention to this subject, and to him we are indebted for the discovery of the Galvanic battery or trough, fig. 19, being a much more convenient form of the Voltaic pile. It was soon found from repeated experiments that the pile or battery performed the parts of a powerful agent in chemistry, and water; sulphuric acid, &c. were decomposed by it. Mr. Davy, professor of chemistry at the Royal Institution, discovered that the electricity is produced by a chemical action of the different substances on each other, and that the effect is greater or less as this action is so; and that therefore two dissimilar metals are not essential to the Galvanic process. This ingenious and truly indefatigable philosopher has at length, by the application of his principle, succeeded in the decomposition of the fixed alkalis and some of the earths, which had before been ranked among the simple bodies. This brilliant discovery appears to open an extensive field for further investigations and acquisitions to our stock of knowledge. The identity, however, of the Galvanic and electric fluid had been disputed by many philosophers,

philosophers, till all doubt was removed by the experiments of Dr. Wollaston, who decomposed water, and produced several other Galvanic effects, by common electricity, which before had not been attempted, and which had been considered as objections to the theory which considers the Galvanic and electric fluids to be the same; so that the principal difference between electricity and Galvanism consists in the mode of exciting, accumulating, and applying the fluid. From the various researches of philosophers the following principles have been established:

1. In common electricity the fluid is excited by the rubbing of an electric or non-conductor, and without the electric no effect of this nature can be produced: in Galvanism the fluid is excited by the conductor alone, without the intervention of electrics, being evolved by the chemical agency of the different substances employed. For the more easily understanding of Galvanic operations, the conductors of electricity have been divided into two classes. 1. Dry and good conductors as metals and charcoal. 2. Water and other oxidating fluids, and the substances which contain those fluids, being the less perfect conductors; this second class may be subdivided into species.

2. To produce the Galvanic action, three different substances at least, which are conductors of electricity, must be placed in contact, so as to form a circuit from one to another; for no sensible effect is produced from two conductors, nor from three when the communication between any two of them is broken by an electric: hence such a combination of three different conductors is called a simple Galvanic circle. This circle may be variously formed: thus if a liquid, as diluted muriatic acid, be put into the vessel A B, fig. 2, and two wires inserted through the cork at B as the wire *z* of zinc, and the wire *c* of platina, silver, or copper, while the wires remain separated at the top no action takes place on the wire *c*, but as soon as the circuit is completed by bringing the wires into contact at the top, the Galvanic action is perceived by the evolution of gas from the wire *c*; separate the wires the effect ceases, connect them again and it is renewed. Thus we see that the circuit must be completed, in order to occasion these striking phenomena, as here the wire *z* communicates with the liquid, the liquid with the wire *c*, and the wire *c* again with the wire *z*, forming, as above stated, a simple Galvanic circle. In like manner if the tube A B, fig. 3, be filled with a liquid, and wires of different metals be inserted through the corks A and B, and these be made to communicate at C G, the circle will be formed, and the like appearances will ensue. These effects will likewise take place if the wires, instead of being brought into contact, be connected by any good conductor, which has no particular chemical action on the others. When the circle is formed as above by two conductors of the first class and one of the second, it is called a Galvanic circle of the first order, but when two of the conductors are of the second class, and one of the first, a Galvanic circle of the second order. Thus let one of the glass-vessels, A B, fig. 4, be filled with diluted nitrous acid, and the other with water, and connected by the copper wire *ab*, a simple Galvanic combination is formed of the second order. If one extremity of a prepared frog be placed in one of the vessels, when the other extremity is brought into contact with the liquid of the other vessel, convulsions will take place. The combination would be more powerful if a solution of the sulphuret of potash be put in the glass-vessel B D, fig. 20, and a silver cup, or salt-cellar A, nearly filled with diluted nitric acid, be placed within it, the communication between the liquids being formed by the prepared frog, the convulsions are strongly excited by the Galvanic influence. If the three conductors be all of the first class, or all of the second, then the effect is seldom sensible. In this case such conductors of the second class as differ more from each other, are more likely to produce a sensible effect than those of the first class. But a proper active simple combination must consist of three different bodies; viz. of one conductor of one class, and two different conductors of the other class. Thus (denoting the bodies of the first class by means of large capital letters, and those of the second class by small letters) the combinations of fig. 5 and 6, are active; but those of fig. 7, 8, 9, 10, and 11, are not active; because that of fig. 7, 8, or 9, consists of two bodies only, and that of fig. 10, or 11, consists of three bodies, of which two are of the same sort, and of course act as a single body. In a single active Galvanic combination, or as it is commonly called, in a simple Galvanic circle, the two bodies of one class must touch each other in one or more

points, at the same time that they are connected together at other points by the body of the other class. Thus, when a prepared frog is convulsed by the contact of the same piece of metal in two different places; then the fluids of those parts, which must be somewhat different from each other, are the two conductors of the second class, and the metal is the third body, or the conductor of the first class. If two metals are used, then the fluids of the prepared animal, differing but little from each other, may be considered as one body of the second class. Thus also, when a person drinks out of a pewter mug, the saliva or moisture of his under lip is one fluid or one conductor of the second class, the liquor in the mug is the other, and the metal is the third body, or conductor of the first class.

3. It seems to be indispensably requisite, that in a simple Galvanic circle, the conductor or conductors of one class should have some chemical action upon the other conductor or conductors; without which circumstance the combination of three bodies will have either no Galvanic action at all, or a very slight one. Farther, the Galvanic action seems to be proportionate to the degree of chemical agency; which seems to shew that such chemical action is the primary cause of the electric phenomena. The most active circles of the first order, are two solids of different degrees of oxidability and a fluid capable of oxidating at least one of the solids. Thus gold, silver, and water, do not form an active Galvanic circle; but the circle will become active if a little nitric acid, or any fluid decomposable by silver, is mixed with the water. A combination of zinc, silver, and water, forms an active Galvanic circle; and the water is found to oxidate the zinc, provided the water holds some atmospherical air, and especially if it contains oxygen gas. But zinc, silver, and water containing a little nitric acid, form a more powerful Galvanic circle, the fluid being capable of acting both upon the zinc and upon the silver. The most powerful Galvanic combinations of the second order, are when two conductors of the second class have different chemical actions on the conductors of the first class, at the same time that they have an action upon each other. Thus copper, or silver, or lead, with a solution of an alkaline sulphuret, and diluted nitrous acid, forms a very active Galvanic circle.

The following tables contain a list of the best combination, beginning with the most powerful, and proceeding in order.

Table of Galvanic circles of the first order, viz. which consist of two conductors of the first class, and one of the second.

Zinc with gold, or charcoal, or silver, or copper, or tin, or iron, or mercury; and water containing a small quantity of any of the mineral acids.

Iron, with gold, or charcoal, or silver, or copper, or tin, and a weak solution of any of the mineral acids, as above.

Tin, with gold, or silver, or charcoal, and a weak solution of any of the mineral acids, as above.

Lead, with gold, or silver, and a weak acid solution, as above.

Any of the above metallic combinations, and common water, viz. water containing atmospherical air, or especially water containing oxygen air.

Copper with gold, or silver, and a solution of nitrate of silver and mercury; or the nitric acid; or the acetous acid.

Silver, with gold, and the nitric acid.

Table of Galvanic circles of the second order, viz. which consist of one conductor of the first class, and two of the second.

Charcoal, or	with water, or with	and a solution of ni-
Copper, or	a solution of any	trous acid, or oxyge-
Silver, or	hydrogenated alka-	nated muriatic acid,
Lead, or	line sulphurets, ca-	&c. capable of act-
Tin, or	pable of acting on	ing upon all the me-
Iron, or	the first three me-	tals.
Zinc,	tals only;	

The action of a simple Galvanic circle seems to be in some measure dependent upon the quantity of surface of contact between the acting bodies. A higher temperature, within certain limits, renders the activity of the circle greater than a lower temperature. The activity of a Galvanic circle is not altered by the interposition of such conductors as have no action upon the adjoining conductors of the circle. Thus if a circle consists of zinc, gold, and water; and if you interpose a piece of iron, or of silver, or both, between

between the zinc and the gold; the activity of the circle will not be altered. Hence it appears that the action of a Galvanic circle may be conveyed through extraneous conductors to a considerable distance; but it must be observed, that the activity is weakened by the great length of the conductors, especially if they are of an imperfect nature. 4. When the three bodies which form a Galvanic circle of the first order are laid one upon the other, but the lower and the upper one do not touch each other; then these two extremes are in opposite electric states, viz. the extremity which is next to that metallic surface that touches the body of the second class, is positive, and the opposite extremity is negative. Thus let copper, zinc, and moistened leather, be laid one upon the other, as in fig. 12, and the upper end W, viz. the wetted leather, will be found possessed of positive electricity; whilst the lower end C, or the copper, will be found negative. 5. The Galvanic effects may be increased to almost any degree, by connecting several of the above-mentioned active combinations, or by a repetition of the same simple Galvanic combination (the most active simple combinations forming the most powerful batteries, and vice versa) provided the simple combinations are disposed so as not to counteract each other. Those batteries are said to be of the first or of the second order, according as the simple combinations, of which they consist, are of the first or of the second order. Thus, if a piece of zinc is laid upon a piece of copper, and a piece of moistened card upon the zinc; then a similar arrangement of three other such pieces laid upon them, and a third arrangement upon this, &c. all in the same order; the whole will form a battery of the first order. But if the arrangement be made by connecting a piece of copper with a piece of cloth moistened with water; the latter with a piece of cloth moistened with a solution of sulphate of potass, and this again with another piece of copper, &c. the whole will form a battery of the second order. The above-mentioned restriction, viz. that the parts of a battery must not counteract each other, will be easily understood by considering that every simple, but interrupted Galvanic combination, has a positive and a negative end; or that in every complete Galvanic circle, the electric fluid circulates in one way only. Thus, if two simple combinations are disposed as in fig. 14, this arrangement will not have any Galvanic power, because the actions of the two simple combinations, or the two currents of electricity, are opposed to each other; the two positive ends being called *p*, and the two negative ends *n*. But if those fixed bodies are disposed as in fig. 15, then the combination will be very active; because, according to the hypothesis, the direction of the electric fluid in each simple arrangement tends the same way, and probably the one accelerates the other. What has been said above of the arrangement of two simple Galvanic combinations, must be likewise understood to hold good with respect to the connection of any number of the same; viz. that they must not counteract each other; or if a certain number of them counteract each other, then the remaining only form the active part of the battery. For instance, if a battery consists of 40 simple combinations, and if 12 of them are placed in a direction contrary to the others; then these 12 will counteract 12 others, and of course the whole battery will have no more power than if it consisted of 16 simple combinations properly disposed. This points out a method of comparing the powers of two batteries; for if those batteries are connected in an inverted order, viz. the positive end of one to touch the negative end of the other; then, on connecting the two other extremities, or on applying them to proper instruments, the whole power will be annihilated, if the separate batteries had equal power; otherwise the power of the whole will be the excess of the power of the most powerful battery above that of the weakest; and the direction, viz. its being positive or negative, will shew to which battery it belongs. It must be observed, with respect to the inactive arrangement of fig. 14, that if one of the separate bodies Z, is removed, then the remaining five bodies will form an active combination; for in that case, W, become one body, and S, S, likewise act as one body. It is almost superfluous to observe, that (as has been said with respect to simple circles) in a Galvanic battery the interposition of conductors that have no particular action, or of the conductors of the same class as the adjoining bodies, does not alter the effect of the battery. These simple arrangements being well understood, the effect of uniting two or more simple Galvanic circles, it will be easy to construct the battery several ways.

We shall here describe the two methods first used and invented by Volta, fig. 16 and 17, and that of Mr. Cruickshank now generally employed, fig. 19. The construction, fig. 16, Volta denominates, a *couronne de tasses*, consisting of glass-tumblers, or china-cups, partly filled with water, or salt and water, &c. and two plates unconnected with each other, viz. a plate of zinc and a plate of silver, are plunged in the fluid of each cup, excepting the first and last cups; but each of those plates must have a sort of tail or prolongation, by which they are so connected that the silver plate of one cup communicates with the zinc-plate of the next, and so on; or they may be connected by some other conductor. The battery, fig. 17, consists of pieces of silver, about as big as half-crowns, pieces of zinc, of an equal size to those of silver, and pieces of card, or cloth, or leather, or other bibulous substance, a little smaller in diameter than the metallic pieces, and soaked in water or in other proper fluid. Those pieces are disposed in the order of silver, zinc, and wet cloth, &c. as indicated by the letters, S, Z, W. The pieces of card, or cloth, &c. must be well soaked in the fluid; but before they are applied, they should be squeezed, in order that the superfluous fluid may not run down the outside of the pile, or insinuate itself between the contiguous pieces of silver and zinc. Those pieces, especially if soaked in plain water, lose their moisture pretty soon, so that they can hardly serve longer than for a day or two; after which time the pile must be decomposed, the metallic pieces cleaned, those of cloth or card soaked again, and the whole arranged as before. The three rods R, R, R, are of glass or of baked wood; and the piece of wood, O, slides freely up, or down the rods. This serves to prevent the falling of the pieces. When such battery is to be very powerful, viz. is to consist of numerous pieces, the best way is to form two or three or more piles, and to join them by pieces of metal, as *c c* in fig. 18, where two piles are joined together, so that *a* is the negative extremity, and *b* is the other or positive extremity of the whole arrangement, or of the two piles considered as one. The battery, fig. 19, consists of a wooden box, or trough, the depth and breadth of which corresponds with the size of the plates. It is of such a length, in general, as to contain fifty plates, allowing a space of about three-eighths of an inch, between each pair of plates. The spaces between the plates are formed by grooves, which are to receive the plates. The plates are first soldered together in pairs, one of copper or silver, and the other of zinc, making one plate of the two. The trough being lined with a cement, formed of bees'-wax and resin, the plates which are previously warmed, are pressed into the grooves, in such order, that the zinc-side of each compound-plate may face one way, and the copper or silver the other. The pair of plates of zinc and silver, which, in the pile, are simply laid upon each other, are in the trough, soldered together, and cemented into the grooves; and the cavity or cells formed by the spaces between each pair of plates, in the trough, being filled with a solution of salt or other appropriate liquid, stands in the stead of the pieces of moistened cloth, between the plates of the pile. Two or more of such batteries may be joined, as has been said of the preceding battery. See fig. 24. It need hardly be observed, that instead of zinc, copper, and water, other combinations may be made according to the table. At present the last-described batteries are constructed with copper, zinc, and water mixed with a small proportion of nitric or muriatic acid. For the construction of such batteries it is immaterial whether the metals are quite pure or slightly alloyed. The wood of which the trough is made should be the oldest and hardest mahogany that can be procured, as being less liable to warp, and it ought to be well put together to prevent leaking. The plates should be of copper and zinc, for though silver be somewhat better than copper, it is not so in proportion to the price. The zinc-plates may be cut out of sheets of malleable zinc, and the copper-plates may be so thin as one ounce to twenty-four square inches of surface. They may be made a little larger than the zinc to lap over the edge at the top, where it may more conveniently be soldered; the other edges need not be soldered, they being sufficiently secured by the cement in the grooves. The length of a trough should be about two feet; they become unwieldy when larger. After the plates are inserted by warming them sufficiently to melt the cement in the grooves, and the whole is polished up, by applying a hot iron, the parts may be varnished with copal, or with common spirit varnish. The action of all these batteries is greatest when

when they are first completed or filled with the fluid; and it declines in proportion as the metal is oxidated, or the fluid loses its power. Hence, after a certain time, not only the fluid must be changed, but the metallic pieces must be cleaned by removing the oxidated surface; which is done either by filing or by rubbing them with sand or sand-paper, or by immersing them for a short time in diluted muriatic acid, and then wiping them with a coarse cloth. The metallic pieces of the battery, fig. 19, may be cleaned by the last method, and may be wiped by introducing a stick with a rag into the cells. When experiments are to be made all the cells of the trough must be filled, within about half an inch of the top, with a liquid, composed of water, with about one twenty-fifth part of the muriatic or the nitric acid. The plates of the trough are shorter than the depth of the trough, by about three-fourths of an inch; so that the trough may be leaned on one side in the filling, for the purpose of letting the liquid run equally into all the cells. If a number of troughs are to be connected together, the communication must be made by pieces of metal, which are inserted into the liquid of one cell of each trough, as represented in fig. 24, at *a, b, c*. In making the connection, it is to be observed, that the zinc-surface of one trough must correspond with the copper one of another, and the zinc of the latter with copper of a third, and so on, for the connecting metals are of strong wire answer very well. After all the troughs are connected together, let the two unconnected ends, at which the experiments are to be made, be as near together as possible. A connection being now formed between the two ends, one of which we shall term the zinc-end, and the other the copper-end, the united energy of the whole will be transmitted through the connecting medium. We may now proceed to notice some of the more striking effects of these combinations. The chemical action of bodies upon each other is increased by the Galvanic arrangement so much, that some of them are by that means enabled to act upon bodies that otherwise they would have no action upon. Fig. 3, represents a glass-tube about four inches long. Two corks are thrust into its apertures *A* and *B*. An oblong piece of zinc, *CD*, is fixed into one of the corks, and is made to project within and without the tube. *EFG* is a silver wire, which being fixed into the other cork, projects with the extremity *E*, within the tube; and its other extremity is bent so as to come near the projecting part of the zinc *C*. Remove one of those corks, and fill the tube with water, in which you must mix a drop or two of muriatic acid; then replace the cork, and you will find that the zinc is acted upon by the diluted acid, is oxidated by it, and bubbles of gas are evolved from it; but the silver wire *E* remains untouched, and no gas whatever is evolved from it. Now, if you bend the silver wire, *FG*, so that its end *G* may touch the zinc at *C*, then the Galvanic circle of silver, zinc, and diluted acid is completed, in consequence of which the diluted acid is enabled to act stronger upon the zinc *D*, which is manifested by the more copious evolution of gas, and is besides enabled to act upon the silver wire; for now you will observe the evolution of gas from the silver *E* also. Break the contact between *G* and *C*, and the silver *E* will cease to yield gas. Form it again, and gas will again proceed from the silver. Instead of silver, zinc, and diluted muriatic acid, you may in the same manner use gold, tin, and diluted nitric acid; and by completing the circle, the acid will be enabled to act upon the gold. It has been observed, that whenever an oxidating influence is exerted at one of the places of contact of the perfect and imperfect conductors, a deoxidating action appears to be produced at the other place. Thus when iron, which oxidates rapidly when forming a circle with silver and common water, is arranged with zinc and common water, it remains perfectly unaltered, whilst the zinc is rapidly acted upon. Fig. 2, represents a more convenient method of performing this experiment. The muscular parts of animals recently dead, and making part of the circuit, will be convulsed as above described. The effects thus produced by a single galvanic circle, become abundantly more striking and interesting from the proper combination of several that is from the action of the Galvanic battery. The battery not only convulses the prepared limbs of a frog, or produces the appearances of a flash of light before the human eye; but it shews all the phenomena of electricity in a very considerable degree. It gives the shock; it affects the electrometer; shews a luminous spark, accompanied with an audible report;

it burns metallic and other combustible bodies; and continues in action for a very long time, viz. until the chemical action between the component parts of the battery is quite exhausted. The following contain a more particular, yet concise, enumeration of those wonderful effects. When the Galvanic battery of the first order consists of twenty repetitions of simple combinations, if you touch with one hand one extremity of the battery, as at *b*, in any one of the above-described batteries (see figs. 17, 18, 19), and apply your other hand to the other extremity of the battery, as at *a*, you will feel a very slight shock, like that which is communicated by a Leyden phial weakly charged, and it will be hardly felt beyond the fingers, or at most the wrists. This shock is felt as often as you renew the contact. If you continue the hands in contact with the extremities *b* and *a*, you will perceive a slight but continued irritation; and, when the hand or other part of the body, which touches the extremity of the battery, is excoriated or wounded, this sensation is disagreeable, and rather painful. The dry skin of the human body is seldom capable of conducting this shock; therefore the touching finger should be well moistened with water, or salt and water. It will be better to immerse a wire that proceeds from one extremity of the battery, in a bason of water, wherein you may plunge one of your hands; then grasping with your other hand well moistened a large piece of metal, for instance, a large silver spoon, touch the other end of the battery with it, and the shock will be felt more distinctly. By this means the shock has been felt when the battery consisted of less than twenty repetitions. Instead of one person, several persons may join hands (which must be well moistened with water,) and on completing the circuit, they will all feel the shock at the same instant. But the strength of the shock is much diminished by its passing through the several persons, or, in general, by passing through less perfect conductors. The shock from a battery consisting of fifty or sixty repetitions of the most active combinations of the first order may be felt as far as the elbows; and the combined force of five or six such batteries will give a shock perhaps much stronger than most men would be willing to receive. The prepared limbs of a frog or other animal are violently convulsed, but soon exhausted of their irritability by the action of a Galvanic battery. This shock is similar to that of a large common electrical battery weakly charged, and not to that of a small Leyden phial fully discharged. The difference consists in this, viz. that the latter contains a small quantity of electric fluid highly condensed; hence its discharge will force its way through perhaps an inch of air; whereas the former contains a vast quantity of electricity, but little condensed; hence its spark, viz. its course through the air, is so very short, that the fingers must be brought almost into perfect contact in order to receive the shock; and such is the case with the Galvanic battery; for the shock from a very powerful battery of this sort will hardly ever force its way through the air, when the extremities of the circle of communication are more than the fortieth of an inch distant, even when those extremities consist of perfect conductors. In this case a small, but very vivid, spark is seen at that extremity, accompanied with an audible, but not strong, report. There is no perceptible difference of appearance between the spark of the positive and that of the negative end of the battery. The first effect of the shock seems to be proportional to the number of plates nearly, without regard to their size. Thus if the number of plates be the same, the first perceptible action is nearly the same, though the plates of the one battery be several times larger than the other; but, in the latter case, the effect is continued with less interruption, as the plates are larger, till at length a constant tremor is produced. If a wire, proceeding from one extremity of a pretty strong battery, be made to communicate with the inside coating, and a wire, which proceeds from the other extremity of the battery, be made to communicate with the outside coating of a common large jar or electrical battery; the latter will become weakly, but almost instantaneously, charged, in the same manner as if it had been charged by a few turns of a common electrical machine; and with that charge you may either give the shock or affect the electrometer, &c. From this and several other experiments it appears that a Galvanic battery produces a vast quantity of electric fluid, but which is little condensed; and indeed it cannot be supposed that the electric fluid could proceed in a very condensed state from an arrangement of bodies, which, whether more or less, are, however,

all good conductors of electricity; for if the fluid were much condensed at one extremity of the battery, and much rarefied at the other extremity, the condensation would soon be made through the pile itself. Indeed, it is difficult to comprehend how this compensation does not take place in all cases. Having mentioned above, that the charge of a battery may be communicated to a common electrical battery, it is almost superfluous to observe, that the same may be communicated to a condenser, or to a multiplier, and from it to the electrometer. If the battery consist of two hundred repetitions, the electrometer will be affected by the simple contact. The spark, or the discharge of a Galvanic battery, when sent through thin inflammable bodies that are in contact with common or oxygen air, sets them on fire, and consumes them with wonderful activity. It fires gunpowder, hydrogen gas, phosphorus, and other combustibles; it renders red-hot, fuses, and consumes very slender metallic wires and metallic leaves. The mode of applying the power of the battery for such purposes is shewn in fig. 21, where AB represents a powerful Galvanic battery; ACDF is a wire which communicates with the last plate of the battery at A; BKIHG is another wire which communicates with the last plate at B. DE, HI, are two glass-tubes, through which those wires pass, and into which they are fastened sufficiently steady. Those tubes serve to move the wires by; for if the operator applies his fingers to the middlemost parts of those tubes, he may move the wires wherever he pleases, without the fear of receiving a shock. If the two extremities F, G, are brought sufficiently near to each other, the spark will be seen between them. It is between those extremities that the combustible substances, or metallic leaf, &c. is to be placed, in order to be fired or consumed. This figure represents the situation of the wires in the act of inflaming gunpowder. A battery consisting of two hundred pairs of metallic plates (viz. copper and zinc, each five inches square) melted twenty-three inches of very fine iron wire. A platina-wire about $\frac{1}{4}$ inch in diameter, was melted into a globule. Fig. 24 is the representation of a compound battery of the same kind, fastened together with the conductors *a, b, c*. A more convenient method is, to fasten the wires to the ends of the universal dischargers E and F, fig. 25, and placing the substances between the points ST on the table HG; also to the ends ST may be adapted spring-sockets for receiving bits of charcoal, or wires of different sorts, &c. When charcoal is to be deflagrated it must be prepared with great care from boxwood, lignum vite, or beech, small bits may have the outside taken off, and be put among sand in a crucible, and heated till the wood be charred. It is best to let it remain in the sand till it is wanted for use, when a piece may be fixed to each rod of the discharger connected with the battery. When the contact is made, a most brilliant deflagration takes place, and may be continued a considerable time, by moving the charcoal as it burns. When oils, alcohol, &c. are to be inflamed, it is best to cover thin metallic substances or charcoal with them. Under the exhausted receiver of the air-pump, the Galvanic battery acts less powerfully than in the open air; but in oxygen air it acts with increased power. The flash of light which appears before the eye of the experimenter, when the eye itself, or some other part not very remote from it, is put in the circuit of a Galvanic combination, does not appear much greater when a battery is employed than when two plates are employed in the manner which has been already mentioned; but when the battery is used, the sensation of a flash may be produced in various ways. If one hand or both be placed in perfect contact with one extremity of the battery, and almost any part of the face brought into contact with the other extremity of the battery, the flash will appear very distinctly; the experimenter being in the dark, or keeping his eyes shut. This flash appears very strong, when a wire which proceeds from one extremity of the battery is held between the teeth, and rests upon the tongue, whilst the other wire is held in the hand. In this case the lips and the tongue are convulsed, the flash appears before the eyes, and a very pungent taste is perceived in the mouth. If any part of the human body, forming part of the circuit of a Galvanic battery, be kept some time in that situation, the irritation or numbness is more or less distinct, and more or less painful, according to the sensibility of the parts concerned. This application is likely to prove most useful as a remedy in various disorders. It is said that it has already proved beneficial in deafnesses and in rheumatisms. It highly deserves to

be tried by medical persons. The most extraordinary phenomena of a Galvanic battery are the chemical effects and the modifications which are produced by it upon the bodies concerned, or upon such as are placed in the circuit, some of which we shall here exhibit. AB, fig. 22, represents a glass-tube, full of distilled water, and having a cork at each extremity. EF is a brass or copper wire, which proceeds from one extremity of a Galvanic battery, and passing through the cork A, projects within the tube. HG is a similar wire, which proceeds from the other extremity of the battery, and comes with its extremity G within the distance of about an inch or two from the wire F. In this situation of things, you will find that bubbles of gas proceed in a constant stream from the surface G of the wire which proceeds from the negative end of the battery; these bubbles of gas, ascending to the upper part of the tube, accumulate by degrees. This gas is pure hydrogen, and may be inflamed. At the same time the other wire F deposits an oxide in the form of a stream or cloud, which gradually accumulates in a greenish form in the water, or on the sides of the tube, and is a perfect oxide of the brass. The wire F is readily discoloured and corroded. If you interrupt the circuit, the production of gas and of oxide ceases immediately. Complete the circuit, and the production of gas re-appears. This production of gas may be observed even where the battery consists of not more than six or eight repetitions of silver, zinc, and water. In short, if the power of the battery be sufficient to oxidate one of the wires of communication, the other wire will afford hydrogen gas; both extremities of the wires being in water. In this experiment it seems that the hydrogen is separated from the water, and is converted into a gaseous state by the wire connected with the negative extremity of the battery; whilst the oxygen unites with and oxidates the wire connected with the positive end of the battery. If you connect the positive end of the battery with the lower wire of the tube, and the negative with the upper, then the hydrogen proceeds from the upper wire, and the lower wire is oxidated. If two wires of gold or platinum are used, which are not oxidable; then the stream of gas issues from each, the water is diminished, and the collected gas is found to be a mixture of hydrogen and oxygen. It explodes violently. A little hole must be made in the lower cork B, to let out the water as the gas evolves. A more suitable apparatus for these experiments, is shewn in fig. 23. AB is a glass-cup, having two platina-wires. Fz and Ec, passing through two perforations in the bottom of the vessel AB; this vessel is partly filled with water, and there is introduced the tube D, close at the top, and filled with water, in some other vessel from which it is transferred, with the mouth downward, by means of a small cup containing water; this is then put over the wires z and c in the vessel AB, and the whole put on the stand GHI, which has a glass-top GH, made to receive AB, and having two notches at *m*, and *n* to receive the wires Fz and Ec. These wires being connected with the two ends of the battery, the gas will be given out by the wires, and collected in the tube D; if a tube be placed over each, the gases will be obtained separately. Or vessels may be suspended over a cup of water, they being filled with water. See fig. 27. In all the batteries of the first order, when the connection is completed, changes take place, which denote the evolution of influences capable of producing from common water oxygen and hydrogen, acid and alkali, in different parts of the body. Thus in the battery with a series of zinc-plates, silver-wires, and common water, oxide of zinc is formed on all the plates of zinc, whilst hydrogen is produced from the silver-wires; and if the water in contact with them be tinged with red cabbage-juice, it becomes green. And in the battery with silver, gold, and weak nitric acid, the silver is dissolved, whilst the acid becomes green, and slowly evolves gas at its points of contact with the gold. The chemical agencies exerted in the compound batteries of the first order can be best observed by the substitution of single metallic wires for some of the plates; for, in this case, the changes taking place in the series with wires, will be exactly analogous to those produced in the series with plates; silver, and all the more oxidable metals, oxidating in water, in the usual place, and gold and platina evolving oxygen gas. Thus, when into two small glass-tubes, connected by a moist animal substance, and filled with distilled water, two gold wires are introduced from a large battery in the proper order, oxygen is produced in one quantity of water, and hydrogen in the other, nearly in the proportions in which they are required to form

form water by combustion: and if the process be continued for some time, the apparatus being exposed to the atmosphere, the water, in the oxygen-giving tube, will become impregnated with an acid (apparently the nitrous); whilst that in the hydrogen-giving tube will be found to hold in solution a fixed alkali. Let the glass-vessel A, fig. 26, have the two tubes, Z and C, ground into its two necks. At the ends, Z and C, of the tubes, are tied bits of bladder, so that any liquid in the tubes may have no tendency to enter the vessel A. The vessel being previously filled with some liquid, the tubes are so inserted that no air may exist between the ends of the tubes; the tubes are also provided with two small caps of ivory or wood, through which the platina-wires, *pp*, are passed, reaching the bottom so near as not to pierce the bladders. The tubes being filled with water, and the wire from the zinc-end of the battery connected with the wire of the tube Z, while that of the copper is attached to that of the tube C, the decomposition of water will speedily commence, the wire in Z affording oxygen gas, while that of C affords hydrogen gas. In a very short time, the liquid of the tube Z, will be found to contain muriatic acid; or rather, the oxy-muriatic; and the tube C, will at the same time be found to contain a fixed alkali. If the tubes be filled with infusion of cabbage, the signs of alkali and acid are very soon observed, from the liquid of Z becoming red, and that of C green. If the connection be reversed, the liquids repossess the blue colour, and if the process be continued, that of Z becomes green, and C red. From some experiments it would appear probable, that the quantities of hydrogen, produced in series, are small, and the quantities of alkali great, in proportion as the surfaces of contact of the least oxidable metals with the water are more extended. All the oxygenated solutions of bodies possessing less affinity for oxygen than nascent hydrogen, are decomposed when exposed to the action of the metal occupying the place of the least oxidable part of the series in the compound circle. Thus, sulphur may be produced from sulphuric acid; and copper and other metals precipitated in the metallic form from their solvents. It is well known that hydrogen gas, in its nascent state, reduces the oxides of metals. Accordingly when the tube, fig.

22 or 23, is filled with a solution of acetite of lead in distilled water, and a communication is made with the battery as above described, no gas is perceived to issue from the wire which proceeds from the negative end of the battery; but, in a few minutes, beautiful metallic needles are perceived on the extremity of this wire; these soon increase, and assume the form of a fern or other vegetable. The lead thus separated is in its perfect metallic state, and very brilliant. When a solution of sulphate of copper is employed, the copper is precipitated in its metallic state; but instead of appearing in crystals, it forms a kind of button, which adheres firmly to the end of the wire. On making the experiment with a solution of nitrate of silver, the silver is precipitated in the form of a beautiful metallic brush, the metal shooting into fine needle-like crystals. If iron be immersed in a solution of sulphate of copper, the latter metal will be precipitated into a metallic form, and will adhere to the surface of the former. Upon silver merely immersed in the same solution, no such effect is produced: but as soon as the two metals, viz. the silver and the copper, are brought into contact, the silver receives a coating of copper. A measure of the intensity of the power in Galvanic batteries, producing chemical changes, may be derived from the quantity of gas it is capable of evolving from water in a given time. By the powerful action of a large Galvanic battery, the illustrious Mr. Davy, professor at the Royal Institution, effected the decomposition of the fixed alkalis, which had hitherto been attempted in vain. A small bit of alkali is laid on a plate of platina connected with one end of the battery, and bringing another piece of platina connected with the other end of the battery into contact with it. A portion of black matter is soon formed, in which is found imbedded small metallic globules; which substance is found to be the base of the alkali, and has been deprived of its oxygen by the Galvanic agency. This base is found to be a metal: that obtained from potass is denominated potassium, and that which constitutes the base of soda is called sodium. These metals are very inflammable, and decompose water, with a bright flash and slight explosion. The same ingenious philosopher has also in some degree succeeded in decomposing the alkaline earths.

GAMBIA, a great river of Africa, which, running from E. to W. falls into the Atlantic ocean, S. of Cape Verd. It overflows annually like the Nile, and is navigable for ships of 150 tons, 500 miles from its mouth.

GAMBEZON, or **GAMBA**, in antiquity, a kind of soft quilted waistcoat, worn under the coat of mail to prevent its hurting the body. It is made of wool or cotton, quilted between two stuffs, and was also called counterpoint.

GAMBOGE, a concreted vegetable juice, partly of a gummy, and partly of a resinous, nature. It is brought to us either in form of orbicular masses, or of cylindrical rolls of various sizes, and is of a dense, compact, and firm texture, and of a beautiful yellow. It is chiefly brought to us from Cambaja, in the East Indies, called also Cambodja and Cambogia; and thence it has obtained its names of cambadium, cambogium, and gambogium. It is obtained from the stalagmites cambogioides, a tree of the East Indies, by wounding the shoot. It is a very rough and strong purge; it operates both by vomit and stool, and both ways with much violence, almost in the instant in which it is swallowed, but yet without griping. It requires caution and judgement in administering it; but those who know how to give it properly, find it an excellent remedy in dropsies, cachexies, jaundice, asthmas, catarrhs, and in the worst cutaneous eruptions. Its dose is from two or three grains to six, eight, or ten: four grains generally operate briskly without vomiting, and eight or ten grains usually vomit briskly, and afterwards purge downwards. It is at present much more esteemed by painters in water-colours than by physicians.

GAME, in law, signifies birds, or prey, taken or killed by fowling or hunting. The property of such animals *feræ naturæ* as are known under the denomination of game, with the right of pursuing, taking, and destroying them, is vested in the king alone, and from him derived to such of his subjects as have received the grants of a chase, a park, or free warren. By the law of nature, indeed, every man, from the prince to the peasant, has an equal

right of pursuing, and taking to his own use, all such creatures as are *feræ naturæ*, and therefore the property of nobody, but liable to be seized by the first occupant. But it follows, (says Blackstone,) from the very end and constitution of society, that this natural right, as well as many others belonging to man as an individual, may be restrained by positive laws enacted for reasons of state, or for the supposed benefit of the community. This restriction may be either with respect to the place in which this right may, or may not, be exercised; with respect to the animals that are the subjects of this right; or with respect to the persons allowed or forbidden to exercise it. And, in consequence of this authority, we find, that the municipal laws of many nations have exerted such power of restraint; have in general forbidden the entering on another man's grounds, for any cause, without the owner's leave; have extended their protection to such particular animals as are usually the objects of pursuit; and have invested the prerogative of hunting and taking such animals in the sovereign of the state only, and such as he shall authorise. Many reasons have concurred for making these constitutions: as, 1. For the encouragement of agriculture and improvement of lands, by giving every man an exclusive dominion over his own soil. 2. For the preservation of the several species of these animals, which would soon be extirpated by a general liberty. 3. For prevention of idleness and dissipation in husbandmen, artificers, and others of lower rank; which would be the unavoidable consequence of universal licence. 4. For prevention of popular insurrections and resistance to the government, by disarming the bulk of the people: which last is a reason oftener meant than avowed, by the makers of forest or game laws. Nor, certainly, in these prohibitions is there any natural injustice, as some have weakly enough supposed: since, as Puffendorf observes, the law does not hereby take from any man his present property, or what was already his own; but barely abridges him of one means of acquiring a future property, that of occupancy; which indeed the law of nature would allow him, but

of which the laws of society have in most instances very justly and reasonably deprived him. Yet, however defensible these provisions in general may be, on the footing of reason, or justice, or civil policy, we must, notwithstanding, acknowledge, that, in their present shape, they owe their immediate original to slavery. It is not till after the irruption of the northern nations into the Roman empire, that we read of any other prohibitions, than that natural one of not sporting on any private grounds without the owner's leave. With regard to the rise and original of our present civil prohibitions, it will be found, that all forest and game laws were introduced into Europe at the same time, and by the same policy, that gave birth to the feudal system; when those swarms of barbarians issued from their northern hive, and laid the foundation of most of the present kingdoms of Europe on the ruins of the western empire. For when a conquering general came to settle the economy of a vanquished country, and to part it out among his soldiers or feudatories, who were to render him military service for such donations; it behoved him, in order to secure his new acquisitions, to keep the rustici or natives of the country, and all who were not his military tenants, in as low a condition as possible, and especially to prohibit them the use of arms. Nothing could do this more effectually than a prohibition of hunting and sporting: and therefore it was the policy of the conqueror to reserve this right to himself, and such on whom he should bestow it; which were only his capital feudatories, or greater barons. And, accordingly, we find, in the feudal constitutions, one and the same law prohibiting the rustici in general from carrying arms, and also proscribing the use of nets, snares, or other engines for destroying the game. This exclusive privilege well suited the martial genius of the troops, who delighted in a sport, which in its pursuit and slaughter bore some resemblance to war. *Vita omnis* (says Caesar, speaking of the ancient Germans) in *venationibus atque in studiis rei militaris consistit*. And Tacitus in like manner observes, that *quoties bella non ineunt, multum venatibus, plus per otium transigunt*. And indeed, like some of their modern successors, they had no other amusement to entertain their vacant hours; they despising all arts as effeminate, and having no other learning than was couched in such rude ditties as were sung at the solemn carousals, which succeeded these ancient huntings. And it is remarkable, that in those nations where the feudal policy remains the most unaltered, the forest or game laws continue in their highest rigour. In France, before the revolution, all game was properly the king's; and in some parts of Germany it is death for a peasant to be found hunting in the woods of the nobility. With us in Britain, also, hunting has ever been esteemed a most princely diversion and exercise. The whole island was replenished with all sorts of game in the times of the Britons; who lived in a wild and pastoral manner, without inclosing or improving their grounds; and derived much of their subsistence from the chace, which they all enjoyed in common. But when husbandry took place under the Saxon government, and lands began to be cultivated, improved, and inclosed, the beasts naturally fled into the woody and desert tracts, which were called the forests; and, having never been disposed of in the first distribution of lands, were therefore held to belong to the crown. These were filled with great plenty of game, which our royal sportsmen reserved for their own diversion, on pain of pecuniary forfeiture for such as interfered with their sovereign. But every freeholder had the full liberty of sporting upon his own territories, provided he abstained from the king's forests. However, upon the Norman conquest, a new doctrine took place; and the right of pursuing and taking all beasts of chace or venary, and such other animals as were accounted game, was then held to belong to the king, or to such only as were authorised under him. And this, as well upon the principles of the feudal law, that the king is the ultimate proprietor of all the lands in the kingdom, they being all held of him as the chief lord, or lord paramount of the fee, and that therefore he has the right of the universal soil, to enter thereon, and to chase and take such creatures at his pleasure: as also upon another maxim of the common law, that these animals are *bona vacantia*, and, having no other owner, belong to the king by his prerogative. As therefore the former reason was held to vest in the king a right to pursue and take them any where, the latter was supposed to give the king, and such as he should authorise, a sole and exclusive right. This right, thus vested in the crown, was exerted with the utmost rigour, at and after the time of

the Norman establishment; not only in the ancient forests, but in the new ones which the Conqueror made, by laying together vast tracts of country, depopulated for that purpose, and reserved solely for the king's royal diversion; in which were exercised the most horrid tyrannies and oppressions, under colour of forest-laws for the sake of preserving the beasts of chace; to kill any of which, within the limits of the forest, was as penal as the death of a man. And, in pursuance of the same principle, king John laid a total interdict upon the winged as well as the four-footed creation; *capturam avium per totam Angliam interdixit*. The cruel and unsupportable hardships, which these forest-laws created to the subject, occasioned our ancestors to be as zealous for their reformation, as for the relaxation of the feudal rigours and the other exactions introduced by the Norman family; and accordingly we find the immunities of *charta de foresta* as warmly contended for, and extorted from the king with as much difficulty, as those of *magna charta* itself. By this charter, confirmed in parliament, (9 Hen. III.) many forests were disafforested, or stripped of their oppressive privileges, and regulations were made in the regimen of such as remained; particularly killing the king's deer was made no longer a capital offence, but only punished by a fine, imprisonment, or abjuration, of the realm. And by a variety of subsequent statutes, together with the long acquiescence of the crown without exerting the forest-laws, this prerogative is now become no longer a grievance to the subject. But as the king reserved to himself the forest for his own exclusive diversion, so he granted out from time to time other tracts of land to his subjects under the names of chaces or parks; or gave them licence to make such in their own grounds; which indeed are smaller forests in the hands of a subject, but not governed by the forest-laws; and by the common law no person is at liberty to take or kill any beasts of chace, but such as hath an ancient chace or park; unless they be also beasts of prey. As to all inferior species of game, called beasts and fowls of warren; the liberty of taking or killing them is another franchise, or royalty, derived likewise from the crown, and called free warren; a word which signifies preservation or custody: as the exclusive liberty of taking and killing fish in a public stream or river is called a free fishery; of which, however, no new franchise can at present be granted by the express provision of *magna charta*, c. 16. The principal intention of granting a man these franchises, or liberties, was in order to protect the game, by giving him a sole and exclusive power of killing it himself, provided he prevented other persons. And no man but he who has a chace or free warren, by grant from the crown, or prescription, which supposes one, can justify hunting or sporting upon another man's soil; nor indeed, in thorough strictness of common law, either hunting or sporting at all. However new this doctrine may seem, it is a regular consequence from what has been before delivered, that the sole right of taking and destroying game belongs exclusively to the king. This appears, as well from the historical deduction here made, as because he may grant to his subjects an exclusive right of taking them; which he could not do, unless such a right was first inherent in himself. And hence it will follow, that no person whatever, but he who has such derivative right from the crown, is by common law intitled to take or kill any beast of chace, or other game whatsoever. It is true, that, by the acquiescence of the crown, the frequent grants of free warren in ancient times, and the introduction of new penalties of late by certain statutes for preserving the game; this exclusive prerogative of the king is little known or considered; every man that is exempted from these modern penalties looking upon himself as at liberty to do what he pleases with the game: whereas the contrary is strictly true, and that no man, however well qualified he may vulgarly be esteemed, has a right to encroach on the royal prerogative by the killing of game, unless he can shew a particular grant of free warren; or a prescription which presumes a grant; or some authority under an act of parliament. As to the latter, there are but two instances wherein an express permission to kill game was ever given by statute; the one by 1 Jac. I. c. 27, altered by 9 Jac. I. c. 11, and virtually repealed by 22 and 23 Ca. II. c. 25, which gave authority, so long as they remained in force, to the owners of free warren, to lords of manors, and to all freeholders having 40*l.* per ann. in lands of inheritance, or 80*l.* for life or lives, or 400*l.* personal estate, (and their servants), to take partridges and pheasants upon their own, or their masters free warren, inheritance, or freehold; the

the other by 5 Ann. c. 14, which empowers lords and ladies of manors to appoint game-keepers, to kill game for the use of such lord or lady; which with some alteration still subsists, and plainly supposes such power not to have been in them before. The truth of the matter is, that these game-laws do indeed qualify nobody, except in the instance of a game-keeper, to kill game: but only to save the trouble and formal process of an action by the person injured, who perhaps too might remit the offence, these statutes inflict additional penalties to be recovered either in a regular or summary way, by any of the king's subjects, from certain persons of inferior rank who may be found offending in this particular. But it does not follow that persons excused from these additional penalties are therefore authorised to kill game. The circumstance of having 100*l.* per ann. and the rest, are not properly qualifications but exemptions. And these persons so exempted from the penalties of the game-statutes, are not only liable to actions of trespass by the owners of the land; but also, if they kill game within the limits of any royal franchise, they are liable to the actions of such who may have the right of chase or free warren therein. Upon the whole, it appears, that the king, by his prerogative, and such persons as have, under his authority, the royal franchise of chase, park, or free warren, (see these articles,) are the only persons who may acquire any property, however fugitive and transitory, in these animals *feræ naturæ*, while living; which is said to be vested in them *propter privilegium*. And such persons as may thus lawfully hunt, fish, or fowl, *ratione privilegii*, have only a qualified property in these animals: it not being absolute or permanent, but lasting only so long as the creatures remain within the limits of such respective franchise or liberty, and ceasing the instant they voluntarily pass out of it. It is held indeed, that if a man starts any game within his own grounds, and follows it into another's, and kills it there, the property remains in himself. And this is grounded on reason and natural justice; for the property consists in the possession; which possession commences by the finding it in his own liberty, and is continued by the immediate pursuit. And so, if a stranger starts game in one man's chase or free warren, and hunts it into another liberty, the property continues in the owner of the chase or warren; this property arising from privilege, and not being changed by the act of a mere stranger. Or if a man starts game on another's private grounds, and kills it there, the property belongs to him on whose grounds it was killed, because it was also started there; this property arising *ratione soli*. Whereas if, after being started there, it is killed in the grounds of a third person, the property belongs not to the owner of the first ground, because the property is local; nor yet to the owner of the second, because it was not started in his soil; but it vests in the person who started and killed it, though guilty of a trespass against both the owners. See **LAW, RESPECTING GAME**.

GAMES, in antiquity, were public diversions, exhibited on solemn occasions. Such among the Greeks were the Olympic, Pythian, Isthmian, Nemean, &c. games; and, among the Romans, the Apollinarian, Circensian, Capitoline, &c. games. See **APOLLINARIAN, OLYMPIC, PYTHIAN, &c.**

GAMES, MODERN, are usually distinguished into those of exercise and address, and those of hazard. To the first belong chess, tennis, billiards, &c. and to the latter those performed with cards, or dice, as back-gammon, ombre, picquet, whist, &c. See these articles.

GAMELIA, in Grecian antiquity, a nuptial feast, or rather sacrifice, held in the ancient Greek families on the day before a marriage.

GAMELION, in the ancient chronology, was the eighth month of the Athenian year, containing twenty-nine days, and answering to the end of January and beginning of February.

GAMELORA, an island in the Mediterranean, near the N. E. coast of Tunis, three miles E. of Cape Zibech.

GAMET, an island of Denmark, three miles from the Continent, and eight W. S. W. of Ripen.

GAMING, the art of playing or practising any game, particularly those of hazard; as cards, dice, tables, &c. Gaming has at all times been considered as of pernicious consequence to the commonwealth; and is therefore severely prohibited by law. It is esteemed a practice intended to supply, or retrieve, the expences occasioned by luxury; it being a kind of tacit confession, that the company therein engaged do, in general, exceed the bounds of

their respective fortunes; and therefore they cast lots to determine upon whom the ruin shall at present fall, that the rest may be saved a little longer. But, taken in any light, it is an offence of the most alarming nature; tending, by necessary consequence, to promote public idleness, theft, and debauchery, among those of a lower class; and, among persons of a superior rank, it has frequently been attended with the sudden ruin and desolation of ancient and opulent families, an abandoned prostitution of every principle of honour and virtue, and too often has ended in suicide. To restrain this pernicious vice among the inferior sort of people, the statute 33 Hen. VIII. c. 9, was made; which prohibits to all but gentlemen, the games of tennis, tables, cards, dice, bowls, and other unlawful diversions there specified, unless in the time of Christmas, under pecuniary pains and imprisonment. And the same law, and also the statute 23 Geo. II. c. 24, inflict pecuniary penalties, upon the master of any public house, wherein servants are permitted to game, as well as upon servants themselves who are found gaming there. But this is not the principal ground of complaint; it is the gaming in high life that demands the attention of the magistrate; a passion to which every valuable consideration is sacrificed, and which we seem to have inherited from our ancestors, the ancient Germans; whom Tacitus describes to have been bewitched with the spirit of play to a most exorbitant degree. "They addict themselves (says he) to dice (which is wonderful) when sober, and as a serious employment; with such a mad desire of winning or losing, that, when stript of every thing else, they will stake at last their liberty, and their very selves. The loser goes into a voluntary slavery; and, though younger and stronger than his antagonist, suffers himself to be bound and sold. And this perseverance in so bad a cause they call the point of honour; *ea est in re prava pervicacia, ipsi fidem vocant*." One would almost be tempted to think Tacitus was describing a modern Englishman. When men are thus intoxicated with so frantic a spirit, laws will be of little avail: because the same false sense of honour that prompts a man to sacrifice himself, will deter him from appealing to the magistrate. Yet it is proper that laws should be, and be known publicly, that gentlemen may consider what penalties they wilfully incur, and what a confidence they repose in sharpers; who, if successful in play, are certain to be paid with honour, or, if unsuccessful, have it in their power to be still greater gainers by informing.

GAMING, CHANCE IN. Hazard, or chance, is a matter of mathematical consideration, because it admits of more and less. Gamblers either set out upon an equality of chance, or are supposed to do so. This equality may be altered in the course of the game, by the greater good fortune or address of one of the gamblers, whereby he comes to have a better chance, so that his share in the stakes is proportionably better than at first. This more and less runs through all the ratios between equality and infinite difference, or from an infinitely little difference till it come to an infinitely great one, whereby the game is determined. The whole game, therefore, with regard to the issue of it, is a chance of the proportion the two shares bear to each other. The probability of an event is greater or less, according to the number of chances by which it may happen, compared with all the chances by which it may either happen or fail. M. de Moivre, in a treatise de Mensura Sortis, has computed the variety of chances in several cases that occur in gaming, the laws of which may be understood by what follows. Suppose p the number of cases in which an event may happen, and q the number of cases wherein it may not happen, both sides have the degree of probability, which is to each other as p to q . If two gamblers, A and B, engage on this footing, that, if the cases p happen, A shall win; but if q happen, B shall win, and the stake be

a ; the chance of A will be $\frac{p a}{p+q}$, and that of B, $\frac{q a}{p+q}$; consequently,

if they sell the expectancies, they should have that for them respectively. If A and B play with a single die, on this condition, that, if A throw two or more aces at eight throws, he shall win; otherwise B shall win; What is the ratio of their chances? Since there is but one case wherein an ace may turn up, and five wherein it may not, let $a = 1$, and $b = 5$. And again, since there are eight throws of the die, let $n = 8$; and you will have $\frac{a + b n - b n - 1}{n a b n - 1}$, to $\frac{b n + n a b n - 1}{n a b n - 1}$: that is, the chance of A will be to that of B as 663991 to 1015625, or nearly as two to three. A and B are engaged at single quito; and, after playing some time, A wants four.

four of being up, and B 6; but B is so much the better gamester, that his chance against A upon a single throw would be as three to two; What is the ratio of their chances? Since A wants four, and B six, the game will be ended at nine throws; therefore, raise $a + b$ to the ninth power, and it will be $a^9 + 9a^8b + 36a^7b^2 + 84a^6b^3 + 126a^5b^4 + 126a^4b^5 + 84a^3b^6 + 36a^2b^7 + 9ab^8 + b^9$; call a 3; and b 2, and you will have the ratio of chances in numbers, viz. 1759077 to 194048. A and B play at single quito, and A is the best gamester, so that he can give B two in three: What is the ratio of their chances at a single throw? Suppose the chances as z to 1, and raise $z + 1$ to its cube, which will be $z^3 + 3z^2 + 3z + 1$. Now since A could give B two out of three, A might undertake to win three throws running; and consequently the chances in this case will be as z^3 to $3z^2 + 3z + 1$. Hence $z^3 = 3z^2 + 3z + 1$; or $2z^3 = z^3 + 3z^2 + 3z + 1$. And therefore $z\sqrt[3]{2} = z + 1$; and consequently, $z = \sqrt[3]{2} - 1$. The chances, therefore, are

$\sqrt[3]{2} - 1$, and 1, respectively. Again, suppose I have two wagers depending, in the first of which I have three to two the best of the lay, and in the second, seven to four; What is the probability I win both wagers? I. The probability of winning the first is $\frac{3}{5}$, that is the number of chances I have to win, divided by the number of all the chances: the probability of winning the second is $\frac{7}{11}$; therefore, multiplying these two fractions together, the product will be $\frac{21}{55}$, which is the probability of winning both wagers. Now, this fraction being subtracted from 1, the remainder is $\frac{34}{55}$, which is the probability I do not win both wagers: therefore the odds against me are 34 to 21. II. If I would know what the probability is of winning the first, and losing the second, I argue thus; the probability of winning the first is $\frac{3}{5}$, the probability of losing the second is $\frac{4}{11}$; therefore multiplying $\frac{3}{5}$ by $\frac{4}{11}$, the product $\frac{12}{55}$ will be the probability of my winning the first, and losing the second; which being subtracted from 1, there will remain $\frac{43}{55}$, which is the probability I do not win the first, and at the same time lose the second. III. If I would know what the probability is of winning the second, and at the same time losing the first, I say thus: The probability of winning the second is $\frac{7}{11}$; the probability of losing the first is $\frac{2}{5}$; therefore, multiplying these two fractions together, the product $\frac{14}{55}$ is the probability I win the second, and also lose the first. IV. If I would know what the probability is of losing both wagers, I say, the probability of losing the first is $\frac{2}{5}$, and the probability of losing the second is $\frac{4}{11}$; therefore the probability of losing them both is $\frac{8}{55}$; which, being subtracted from 1, there remains $\frac{47}{55}$; therefore, the odds of losing both wagers is 47 to 8. This reasoning is applicable to the happening or failing of any events that may fall under consideration. Thus if I would know what the probability is of missing an ace four times together with a die, this I consider as the failing of four different events. Now the probability of missing the first is $\frac{5}{6}$, the second is also $\frac{5}{6}$, the third $\frac{5}{6}$, and the fourth $\frac{5}{6}$; therefore the probability of missing it four times together is $\frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} = \frac{625}{1296}$; which being subtracted from 1, there will remain $\frac{671}{1296}$ for the probability of throwing it once or oftener in four times: therefore the odds of throwing an ace in four times, is 671 to 625. But if the flinging of an ace was undertaken in three times, the probability of missing it three times would be $\frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} = \frac{125}{216}$; which being subtracted from 1, there will remain $\frac{91}{216}$ for the probability of throwing it once or oftener in three times: therefore the odds against throwing it in three times are 125 to 91. Again, suppose we would know the probability of throwing an ace once in four times, and no more: since the probability of throwing it the first time is $\frac{1}{6}$, and of missing it the other three times, is $\frac{5}{6} \times \frac{5}{6} \times \frac{5}{6}$, it follows, that the probability of throwing it the first time, and missing it the other three successive times, is $\frac{1}{6} \times \frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} = \frac{125}{1296}$; because it is possible to hit every throw as well as the first, it follows, that the probability of throwing it once in four throws, and missing it the other three, is $\frac{125}{1296} = \frac{1}{10.368}$; which being subtracted from 1, there will remain $\frac{1295}{1296}$ for the probability of throwing it once, and no more, in four times. Therefore, if one undertake to throw an ace once, and no more, in four times, he has 500 to 796 the worst of the lay, or five to eight very near. Suppose two events are such, that one of them has twice as many chances to come up as the other; what is the probability that the event, which has the greater number of chances to come up, does not happen twice before the

other happens once, which is the case of flinging seven with two dice before four once? Since the number of chances is as two to one, the probability of the first happening before the second is $\frac{2}{3}$, but the probability of its happening twice before it, is but $\frac{2}{3} \times \frac{2}{3}$ or $\frac{4}{9}$; therefore it is five to four, seven does not come up twice before four once. But, if it were demanded, what must be the proportion of the facilities of the coming up of two events, to make that which has the most chances come up twice, before the other comes up once? The answer is 12 to 5 very nearly: whence it follows, that the probability of throwing the first before the second is $\frac{12}{17}$, and the probability of throwing it twice is $\frac{12}{17} \times \frac{12}{17}$, or $\frac{144}{289}$; therefore the probability of not doing it is $\frac{145}{289}$; therefore the odds against it are as 145 to 144, which comes very near to an equality. Suppose there is a heap of 13 red cards, and another heap of 13 black cards, What is the probability, that, taking one card at a venture out of each heap, I shall take out the two aces? The probability of taking the ace out of the first heap is $\frac{1}{13}$, the probability of taking the ace out of the second heap is $\frac{1}{13}$; therefore the probability of taking out both aces is $\frac{1}{13} \times \frac{1}{13} = \frac{1}{169}$, which being subtracted from 1, there will remain $\frac{168}{169}$; therefore the odds against me are 168 to 1. In cases where the events depend on one another, the manner of arguing is somewhat altered. Thus, suppose that out of one single heap of 13 cards of one colour I should undertake to take out first the ace; and, secondly, the two: though the probability of taking out the ace be $\frac{1}{13}$, and the probability of taking out the two be likewise $\frac{1}{13}$; yet, the ace being supposed as taken out already, there will remain only 12 cards in the heap, which will make the probability of taking out the two to be $\frac{1}{12}$; therefore the probability of taking out the ace, and then the two, will be $\frac{1}{13} \times \frac{1}{12}$. In this last question the two events have a dependence on each other; which consists in this, that one of the events being supposed as having happened, the probability of the other's happening is thereby altered. But the case is not so in the two heaps of cards. If the events in question be n in number, and be such as have the same number a of chances by which they may happen, and likewise the same number b of chances by which they may fail, raise $a + b$ to the power n . And if A and B play together, on condition that if either one or more of the events in question happen, A shall win, and B lose, the probability of A's winning will be

$\frac{a + b^n - b^n}{a + b^n}$; and that of B's winning will be $\frac{b^n}{a + b^n}$;

for when $a + b$ is actually raised to the power n ; the only term in which a does not occur is the last b^n ; therefore all the terms but the last are favourable to A. Thus if $n = 3$, raising $a + b$ to the cube $a^3 + 3a^2b + 3ab^2 + b^3$, all the terms but b^3 will be favourable to A; and therefore the probability of A's winning will be $\frac{a^3 + 3a^2b + 3ab^2}{a^3 + 3a^2b + 3ab^2 + b^3}$, or $\frac{a + b^3 - b^3}{a + b^3}$; and the probability of B's winning will be $\frac{b^3}{a + b^3}$.

But if A and B play on condition, that if either two or more of the events in question happen, A shall win; but in case one only happen, or none, B shall win; the probability of A's winning will be $\frac{a + b^n - nab^{n-1} - b^n}{n + b^n}$; for the only two terms

in which aa does not occur are the two last, viz nab^{n-1} and b^n . See CHANCES. The reader may also consult "Clarks laws of Chance," and "Simpson's Nature and Laws of Chance."

GAMING, LAWS AGAINST. By stat. 16. Car. II. c. 7, if any person by playing or betting shall lose more than 100l. at one time, he shall not be compellable to pay the same; and the winner shall forfeit treble the value, one moiety to the king, the other to the informer. The statute 9 Ann. c. 14, enacts, that all bonds and other securities, given for money won at play, or money lent at the time to play withal, shall be utterly void: that all mortgages and incumbrances of lands, made upon the same consideration; shall be and enure to the heir of the mortgager: that, if any person at one time loses 10l. at play, he may sue the winner, and recover it back by action of debt at law; and, in case the loser does not; any other person may sue the winner for treble the sum so lost; and the plaintiff in either case may examine the defendant himself upon oath: and that in any of these suits no privilege

vilege of parliament shall be allowed. The statute farther enacts, that if any person cheats at play, and at one time wins more than 10l. or any valuable thing, he may be indicted thereupon, and shall forfeit five times the value, shall be deemed infamous, and suffer such corporal punishment as in case of wilful perjury. By several statutes of the reign of king George II. all private lotteries by tickets, cards, or dice (particularly the games of faro, basset, ace of hearts, hazard, passage, rolly-polly, and all other games with dice, except backgammon), are prohibited under a penalty of 200l. for him that shall erect such lotteries, and 50l. a-time for the players. Public lotteries, unless by authority of parliament, and all manner of ingenious devices, under the denomination of sales or otherwise, which in the end are equivalent to lotteries, were before prohibited by a great variety of statutes under heavy pecuniary penalties. But particular descriptions will be ever lame and deficient, unless all games of mere chance are at once prohibited: the invention of sharpers being swifter than the punishment of the law, which only hunts them from one device to another. The statute 13. Geo. II. c. 19, to prevent the multiplicity of horse-races, another fund of gaming, directs that no plates or matches under 50l. value shall be run, under penalty of 200l. to be paid by the owner of each horse running, and 100l. by such as advertise the plate. By statute 18 Geo. II. c. 34, the statute 9 Ann. is farther enforced, and some deficiencies supplied: the forfeitures of that act may now be recovered in a court of equity; and, moreover, if any man be convicted, upon information or indictment, of winning or losing at any sitting 10l. or 20l. within 24 hours, he shall forfeit five times the sum. Thus careful has the legislature been to prevent this destructive vice: which may shew that our laws against gaming are not so deficient, as ourselves and our magistrates in putting those laws in execution.

GAMMON. See BACK-GAMMON.

GAMMONING, among seamen, a term denoting the several turns of a rope which are taken round the bowsprit, and reeved through holes in knees of the head, for the greater security of the bowsprit.

GAMMUT. See GAMUT.

GAMPS, a town of the Helvetic republic, partly in the canton of Schweitz, and partly in that of Glaris; 5 miles S. of Appenzel.

GAMUT, [*gama*, Ital.] the scale of musical notes.

GAMUT, **GAMMUT**, or **GAM-UT**. See MUSIC. The invention of this scale is owing to Guido Aretin, monk of Arezzo, in Tuscany, about A. D. 1009; though it is not so properly an invention, as an improvement on the diagram or scale of the ancients. See ARETIN. Several alterations have been made in the gamut; M. le Maire, particularly, has added a 7th note; viz. *sz*; and the English usually throw out both *ut* and *sz*, and make the other five serve for all.

GAN, a city of China, of the first rank; capital of the province of Se-tchuen.

GAN, a town of France, in the department of the Lower Pyrenees, $4\frac{1}{2}$ miles S. of Pau.

GANARA, a populous and fertile country of Africa, on the banks of the Niger.

GANARA, the capital of the above country. Lon. 16. 0. E. Lat. 12. 20. N.

GANDELU, a town of France, in the department of Aisne, 8 miles W. N. W. of Chateau Thierry.

GANDER, in ornithology. See ANAS.

GANDIA, a sea-port of Spain in Valencia, 28 miles S. of Valencia.

GANDJA, or **GANGEA**, a town of Asia, in Georgia, 15 miles N. W. of Baku, and 100 S. E. of Teflis.

GANDICOT, or **GANDICOTTA**, a town and fort of Hindostan, in the circar of Cuddapa, on a mountain near the Penner, 87 miles N. W. of Nellore.

GANDINA, or **GANDINO**, a populous town of Italy, 10 miles N. W. of Bergamo.

GANET ISLANDS, a cluster of small isles, near the E. coast of Labrador. Lon. 56. 10. W. Lat. 54. 0. N.

GANG, in sea-affairs, a select number of a ship's crew appointed on any particular service, and commanded by an officer suitable to the occasion.

GANG-BOARD is a plank with several steps nailed to it, for the

convenience of walking into, or out of, a boat upon the shore, where the water is not deep enough to float the boat close to the landing-place.

GANG-WAY, a narrow platform, or range of planks, laid horizontally along the upper part of a ship's side, from the quarter-deck to the fore-castle, and is peculiar to ships that are deep-waisted, for the convenience of walking more expeditiously fore and aft than by descending into the waist: it is fenced on the outside by iron stanchions, and ropes or rails, and in vessels of war with a netting, in part of which the hammocks are stowed. In merchant-men it is frequently called the gang-board. The same term is applied to that part of a ship's side, both within and without, by which persons enter and depart; it is provided with steps nailed upon the ship's side, nearly as low as the surface of the water, and sometimes furnished with a railed accommodation ladder.

GANGELT, a town of Germany, in Westphalia, now in the department of the Roer, 12 miles S. S. E. of Ruremond.

GANGES, a large and celebrated river of India. It rises in the mountains which border on Little Thibet, in 96° lon. E. and 35° 45' lat. N. It crosses several kingdoms, running from N. to S. and falls into the bay of Bengal by several mouths. The waters are lowest in April and May, and highest before the end of September. It overflows yearly like the Nile; and renders Bengal as fruitful as the Delta in Egypt. The people in these parts hold the water of this river in high veneration; and it is visited annually by a prodigious number of pilgrims from all parts of India. The British have several settlements on this river. The greatest happiness that many of the Indians wish for, is to die in this river.

GANGES, a town of France, in the department of Herault, 20 miles N. E. of Lodeve, and 21 N. of Montpellier.

GANGES ISLANDS, two small islands between Borneo and the Gulf of Siam. Lon. 106. 45. E. Lat. 4. 55. N.

GANGLION, [*γανγλιον*,] in anatomy, a knot frequently found in the course of the nerves, and which is not morbid; for wherever any nerve sends out a branch, or receives one from another, or where two nerves join together, there is generally a ganglion or plexus, as may be seen at the beginning of all the nerves of the medulla spinalis, and in many other places of the body.

GANGLION, in surgery, a hard tubercle, generally moveable, in the external or internal part of the carpus, upon the tendons or ligaments in that part; usually without any pain to the patient.

GANGRENE, is a very great and dangerous degree of inflammation, wherein the parts affected begin to corrupt. See MEDICINE and SURGERY.

GANI, or **COULOR**, a town of India, 131 miles E. of Bag-nagar.

GANJAM, a town of Hindostan, on the bay of Bengal. Lon. 85. 20. E. Lat. 19. 22. N.

GANTLOPE, in sea-affairs, commonly pronounced gantlet, is a race which a criminal is sentenced to run in a vessel of war for felony, or some other heinous offence. The whole ship's crew is disposed in two rows, standing face to face on both sides the deck, each person being furnished with a small twisted cord, having two or three knots in it; the delinquent is then stripped naked above the waist, and obliged to pass forward between the two rows, a certain number of times, rarely exceeding three, during which, every person is enjoined to give him stripes as he runs along: this is called "running the gantlet," and is seldom inflicted but for crimes which excite general antipathy among the seamen.

GANYMEDES, in mythology, a beautiful youth of Phrygia, son of Tros and brother to Ilus, kings of Troy; or, according to Lucian, the son of Dardanus. Jupiter was charmed with him; and carrying him away, made him his cup-bearer in the room of Hebe.

GAOL, [*geol*, Welsh; *geole*, Fr.] a prison, or place of legal confinement. Every county has two gaols, one for debtors, which may be any house where the sheriff pleases; the other for the peace and matters of the crown, which is the county-gaol. If a gaol be out of repair, or insufficient, &c. justices of peace, in their quarter-sessions, may contract with workmen for the rebuilding or repairing of it: and by their warrant order the sum agreed on for that purpose to be levied on the several hundreds, and other divisions

divisions in the county by a just rate, 11 and 12 Will. III. c. 19. See PRISON.

GAOL-DELIVERY. The administration of justice being originally in the crown, in former times our kings in person rode through the realm once in seven years, to judge of and determine crimes and offences; afterwards justices in eyre were appointed; and since, justices of assize and gaol-delivery, &c. A commission of gaol-delivery is a patent, in nature of a letter from the king to certain persons, appointing them his justices, or two or three of them, and authorising them to deliver his gaol, at such a place, of the prisoners in it: for which purpose it commands them to meet at such a place, at the time they themselves shall appoint; and informs them, that, for the same purpose, the king hath appointed his sheriff of the same county to bring all the prisoners of the gaol, and their attachments, before them at the day appointed. The justices of gaol-delivery are empowered by the common law to proceed upon indictments of felony, trespass, &c. and to order to execution or reprieve: they may likewise discharge such prisoners, as on their trials are acquitted, and those against whom, on proclamation being made, no evidence has appeared: they have authority to try offenders for treason, and to punish many particular offences, by statute 2 Hawk. 24, 2 Hale's Hist. Placit. Cor. 35.

GAOLER, the keeper of a gaol or prison. Sheriffs are to make such gaolers for whom they will be answerable: but if there be any default in the gaoler, an action lies against him for an escape, &c. yet the sheriff is most usually charged; 2 Inst. 592. Where a gaoler kills a prisoner by hard usage, it is felony; 3 Inst. 52. No fee shall be taken by gaolers, but what is allowed by law, and settled by the judges, who may determine petitions against their extortions, &c. 2 Geo. II. c. 22.

GAONS, a certain order of Jewish doctors, who appeared in the East, after the closing of the Talmud. The word Gaons signifies excellent, or sublime; as in the divinity-schools we formerly had Irrefragable, Sublime, Resolute, Angelic, and Subtile doctors.

GAP, in geography, a town of France, the capital of the department of the Upper Alps, 15 miles S. of Grenoble. Lat. 44° 33' 47" N. Lon. from Greenwich 6° 4' 47" E.

GAPENCOIS, a late county of France, of which Gap was the capital. It is now included in the department of Upper Alps.

GARABUSA, an island in the Mediterranean, near the W. coast of Candia. Lon. 41. 8. E. Lat. 35. 36. N.

GARAMA, in ancient geography, the capital of the Garamantes in Lybia Interior; near the spring of the Cinyphus, now in ruins.

GARBE, in heraldry, a sheaf of any kind of grain, borne in several coats of arms, and said to represent summer.

GARBOARD-STRAKE, the plank next the keel of a ship, one edge of which is run into the rabbet made in the upper edge of the keel on each side.

GARCINIA, in botany, a genus of the monogynia order, and dodecandria class of plants; natural order, Bicornes. Calyx four-leaved, inferior; petals four; berry eight-seeded, crowned with the peltate stigma. There are three species.

GARD, in geography, a department of France, comprehending part of the late province of Languedoc. Nismes is the capital.

GARD, an ancient Roman aqueduct in France, 9 miles N. E. of Nismes, erected, it is supposed, by Agrippa, in the time of Augustus Cæsar, to convey to Nismes the water of the spring of Eure, which rises near Uzes.

GARDA, an open town of Maritime Austria, in the Veronese,

N. of Lacize, 17 miles N. W. of Verona. Lat. 45. 34. N. Lon. from Greenwich 10. 58. E.

GARDANT, or **GUARDANT**, in heraldry, denotes any beast full-faced and looking right forward.

GARDEIAH, a town of Africa, the capital of Beni-Mezzab. Lon. 2. 30. E. Lat. 32. 15. N.

GARDEN. See **GARDENING**.

GARDEN BAY, a bay on the E. coast of Newfoundland. Lon. 54. 50. W. Lat. 49. 42. N.

GARDENS, FLOATING. Abbé Clavigero, in his History of Mexico, says, that when the Mexicans were brought under subjection to the Colhuan and Tepanecan nations, and confined to the miserable little islands on the lake of Mexico, they had no land to cultivate, until necessity compelled them to form moveable fields and gardens, which floated on the waters of the lake. The method which they adopted, to make these, and which they still practise, is extremely simple. They plait and twist together willows and roots of marsh-plants or other materials, which are light, but capable of supporting the earth firmly united. Upon this foundation they lay the light bushes which float on the lake; and over all, the mud and dirt which they draw up from the bottom. Their regular figure is quadrangular; their length and breadth various; but generally they are about eight perches long, and not more than three in breadth, and have less than a foot of elevation above the surface of the water. These were the first fields which the Mexicans had after the foundation of Mexico; there they first cultivated maize, pepper, and other plants. In time, as these fields became numerous from the industry of the people, they cultivated gardens of flowers and odoriferous plants, which they employed in the worship of their gods, and for the recreation of their nobles. At present they cultivate flowers and every sort of garden-herbs upon them. Every day at sun-rise, innumerable vessels loaded with various kinds of flowers and herbs, cultivated in those gardens, arrive by the canals, at the great market-place of that capital. All plants thrive in them surprisingly; the mud of the lake affords a very fertile soil, and requires no water from the clouds. In the large gardens there is commonly a little tree, and even a little hut to shelter the cultivator, and defend him from rain or the sun. When the Chinampa, or owner of a garden, wishes to change his situation, to remove from a disagreeable neighbour, or to come nearer to his own family, he gets into his little vessel, and by his own strength alone if the garden is small, he tows it after him, and conducts it wherever he pleases. That part of the lake, where these floating gardens are, is a place of high recreation, where the senses receive all possible gratification.

GARDENS, HANGING, in antiquity, gardens raised on arches by Nebuchadnezzar, king of Babylon, to gratify his wife Amyctis, daughter of Astyages, king of Media. Q. Curtius makes them equal in height to the walls of the city, viz. 50 feet. They contained a square of 400 feet on every side, and were carried up into the air in several terraces laid above one another, and the ascent from terrace to terrace was by stairs ten feet wide. The arches sustaining the whole pile were raised above one another, and it was strengthened by a wall, surrounding it on every side, of 22 feet in thickness. The mould or earth was of such a depth as to admit the largest trees to take root and grow: and it was covered with various kinds of trees, plants, and flowers. In the upper terrace there was an engine, whereby water was drawn up out of the river for watering the whole garden.

GARDENIA, in botany, a genus of the pentandria monogynia class and order; natural order, Contorta. Corolla one-petaled, contorted or twisted; stigma lobed; berry inferior, two to four-celled, many-seeded. There are fifteen species.

GARDENING.

GARDENING, is a branch of agriculture applied to the management and cultivation of gardens.

HISTORY.

Gardening, says Mr. Walpole, in his History of Modern Gardening, was probably one of the first arts that succeeded to that of

building houses, and naturally attended property and individual possession. Culinary, and afterwards medicinal herbs, were the objects of every head of a family: it became convenient to have them within reach, without seeking them at random in woods, in meadows, and on mountains, as often as they were wanted. When the earth ceased to furnish spontaneously all those primitive luxuries,

ries, and culture became requisite, separate inclosures for rearing herbs grew expedient. Fruits were in the same predicament; and those most in use, or that demanded attention, must have entered into and extended the domestic inclosure. Noah planted a vineyard, and drank of the wine. Thus we acquired vineyards, as well as kitchen-gardens, and orchards. No doubt the prototype of all these sorts was the garden of Eden; but as Paradise was a great deal larger than any gardens we read of afterwards, being inclosed by the rivers Pison, Gihon, Hiddekel, and Euphrates; as every tree, that was pleasant to the sight and good for food grew in it; and as two other trees were likewise found there, of which not a slip or sucker remains; it does not belong to the present discussion. After the Fall, nobody was suffered to enter into the garden; and the poverty and necessities of our first ancestors hardly allowed them time to make improvements in imitation of it, supposing any plan had been preserved. A cottage and a slip of ground for a cabbage and a gooseberry-bush, such as we see by the side of a common, were in all probability the earliest seats and gardens; a well and bucket succeeded to the Pison and Euphrates. As settlements increased, the orchard and vineyard followed; and the earliest princes of tribes possessed just the necessities of a modern farmer. The eastern gardens appear to have been planted adjoining to the house or palace to which they belonged. Thus, king Ahasuerus went immediately from the banquet of wine to walk in the garden of the palace. Esther vii. 7. The garden of Cyrus, at Sardis, mentioned by Xenophon, seems to have been contiguous to the palace; as was that of Attalus, mentioned by Justin, l. 36, c. 4. The hanging-gardens at Babylon were not so much adjacent to the palace as a part of the palace itself, since several of the royal apartments were beneath them. Diod. lib. 2. We are not certain what the taste for gardening was among the Greeks. The Academus was a wooded shady place; and the trees appear to have been of the olive-species. It was situated beyond the limits of the walls, and adjacent to the tombs of the heroes; and though we are not informed of the particular manner in which this grove was laid out, it may be gathered from Pausanius's Attica, that it was elegantly ornamented. At the entrance was an altar dedicated to Love. Within the Academus, were the altars of Prometheus, the Muses, Mercury, Minerva, and Hercules; and at a small distance was the tomb of Plato. So that, in all probability, it was highly adapted by art, as well as nature, to philosophic reflection and contemplation. A taste for gardening does not appear to have prevailed among the Romans, otherwise than as a matter of utility, till a very late period; at least the writers on husbandry, Cato, Varro, Columella, and Palladius, make no mention of a garden as an object of pleasure, but solely with respect to its productions of herbs and fruits. The gardens of Lucullus are the first we find mentioned of remarkable magnificence; though indeed from the extravagance to which these were arrived, it is evident, they could not be the first. Plutarch speaks of them as incredibly expensive, and equal to the magnificence of kings. They contained artificial elevations of ground to a surprising height, of buildings projected into the sea, and vast pieces of water upon land. In short, his extravagance was so great, that he acquired the appellation of the Roman Xerxes. It is not improbable, from the consideration of Lucullus having spent much time in Asia, in a situation wherein he had an opportunity of observing the most splendid constructions of this kind, that these gardens might be laid out in the Asiatic style. The vast masses of building said to have been erected, might have borne some resemblance, in the arrangement and style, to the Babylonian gardens. In the paintings found at Herculaneum are a few traces of gardens, as may be seen in the second volume of the prints. They are small square inclosures, formed by trellis-work and espaliers, and regularly ornamented with vases, fountains, and caretides, elegantly symmetrical, and proper for the narrow spaces allotted to the garden of a house in a capital city. From these remarks, it appears how naturally and insensibly the idea of a kitchen-garden slid into that which has for so many ages been peculiarly termed a garden, and by our ancestors in this country distinguished by the name of a pleasure-garden. A square piece of ground was parted off in early ages for the use of the family:—to exclude cattle, and ascertain the property, it was separated from the fields by a hedge. As pride and design of privacy increased, the inclosure was dignified by walls; and in climes where fruits were not lavished by

the ripening glow of nature and soil, fruit-trees were assisted and sheltered from surrounding winds by the like expedient; for the inundation of luxuries, which have swelled into general necessities, have almost all taken their source from the simple fountain of reason. When nature and prospect were thus excluded, by the custom of making square gardens inclosed with walls, pomp and solitude combined to call for something that might enrich and enliven the insipid and inanimated partition. Fountains, first invented for use, which grandeur loves to disguise and throw out of sight, received embellishments from costly marbles, and at last, to contradict utility, as it were, tossed their waste of waters into air in spouting columns. Art, in the hands of rude man, had at first been made a succedaneum to nature; in the hands of ostentatious wealth, it became the means of opposing nature; and the more it traversed the march of the latter, the more nobility thought its power was demonstrated. Canals, measured by the line were introduced in lieu of meandering streams, and terraces were hoisted aloft in opposition to the facile slopes that imperceptibly unite the valley to the hill. Balustrades defended these precipitate and dangerous elevations, and flights of steps rejoined them to the sub-jacent flat from which the terrace had been dug. Vases and sculpture were added to the unnecessary balconies, and statues furnished the lifeless spot with mimic representations of the excluded sons of men. Thus difficulty and expence were the constituent parts of those sumptuous and selfish solitudes; and every improvement that was made, was but a step farther from nature. The tricks of water-works to wet the unwary, not to refresh the panting spectator, and parterres embroidered in patterns like a petticoat, were but the childish endeavours of fashion and novelty to reconcile greatness to what it surfeited on. To crown these impotent displays of false taste, the sheers were applied to the lovely wildness of form with which nature has distinguished each various species of tree and shrub. The venerable oak, the romantic beech, the useful elm, even the aspiring circuit of the lime, the regular round of the chesnut, and the almost moulded orange-tree, were corrected by such fantastic admirers of symmetry. The compass and square were of more use in plantations than the nurseryman. The measured walk, the quincunx, and the etoile, imposed their unsatisfying sameness on every royal and noble garden. Trees were headed, and their sides pared away; many French groves seem green chests set upon poles. Seats of marble, arbours, and summer-houses, terminated every vista; and symmetry, even where the space was too large to permit its being remarked at one view, was so essential, that, as Pope observed,

— each alley has a brother,
And half the garden just reflects the other.

In Kip's Views of the Seats of our Nobility and Gentry, we see the same firesome and returning uniformity. Every house is approached by two or three gardens, consisting perhaps of a gravel-walk and two grass-plats or borders of flowers. Each rises above the other by two or three steps, and as many walls and terraces, and so many iron gates, that we recollect those ancient romances in which every entrance was guarded by giants or dragons. Yet though these and such preposterous inconveniences prevailed from age to age, good sense in this country had perceived the want of something at once more grand and more natural. And different authors gave descriptions of gardens which they considered as the models of perfection. But as no succeeding generation in an opulent and luxurious country contents itself with the perfection established by its ancestors, more perfect perfection was still sought; and improvements had gone on, till London and Wise had stocked all our gardens with giants, animals, monsters, coats of arms, and mottoes, in yew, box, and holly. Absurdity could go no farther, and the tide turned. Bridgman, the next fashionable designer of gardens, was far more chaste; and whether from good sense, or that the nation had been struck by the admirable paper in the Guardian, No. 173, he banished verdant sculpture, and did not even revert to the square precision of the foregoing age. He enlarged his plans, disdained to make every division tally to its opposite; and though he still adhered much to straight walks with high-clipped hedges, they were only his great lines; the rest he diversified by wilderness, and with loose groves of oak, though still within surrounding hedges. As his reformation gained footing, he ventured, in the royal garden at Richmond, to introduce

roduce cultivated fields, and even morsels of a forest-appearance, by the sides of those endless and tiresome walks that stretched out of one into another without intermission. But this was not till other innovators had broke loose too from rigid symmetry. "But the capital stroke, the leading step to all that has followed, was the destruction of walls for boundaries, and the invention of fosses—an attempt then deemed so astonishing, that the common people called them Ha! Ha's! to express their surprise at finding a sudden and unperceived check to their walk. A sunk fence may be called the leading step, for these reasons. No sooner was this simple enchantment made, than levelling, mowing, and rolling, followed. The contiguous ground of the park without the sunk fence was to be harmonized with the lawn within; and the garden in its turn was to be set free from its prim regularity, that it might assort with the milder country without. The sunk fence ascertained the specific garden; but that it might not draw too obvious a line of distinction between the neat and the rude, the contiguous out-lying parts came to be included in a kind of general design; and when nature was taken into the plan, under improvements, every step that was made pointed out new beauties, and inspired new ideas. At that moment appeared Kent, painter enough to taste the charms of landscape, bold, and opinionative enough to dare and to dictate, and born with a genius to strike out a great system from the twilight of imperfect essays. He leaped the fence, and saw that all nature was a garden. He felt the delicious contrast of hill and valley changing imperceptibly into each other, tasted the beauty of the gentle swell or concave scoop, and remarked how loose groves crowned an easy eminence with happy ornaments; and while they called in the distant view between their graceful stems, removed and extended the perspective by delusive comparison. Thus the pencil of his imagination bestowed all the arts of landscape on the scenes he handled. The great principles on which he worked were perspective, light, and shade. Groups of trees broke too uniform or too extensive a lawn; evergreens and woods were opposed to the glare of the champaign; and where the view was less fortunate, or so much exposed as to be beheld at once, he blotted out some parts by thick shades, to divide it into variety, or to make the richest scene more enchanting by reserving it to a farther advance of the spectator's step. Thus, selecting favourite objects, and veiling deformities by screens of plantations; sometimes allowing the rudest waste to add its soil to the richest theatre: he realized the compositions of the greatest masters in painting. Where objects were wanting to animate his horizon, his taste as an architect could bestow immediate termination. His buildings, his seats, his temples, were more the works of his pencil than of his compasses. We owe the restoration of Greece and the diffusion of architecture to his skill in landscape. But of all the beauties he added to the face of this beautiful country, none surpassed his management of water. Adieu to canals, circular basins, and cascades tumbling down marble steps, that last absurd magnificence of Italian and French villas. The forced elevation of cataracts was no more. The gentle stream was taught to serpentine seemingly at its pleasure; and where discontinued by different levels, its course appeared to be concealed by thickets properly interspersed, and glittered again at a distance, where it might be supposed naturally to arrive. Its borders were smoothed, but preserved their waving irregularity. A few trees scattered here and there on its edges sprinkled the tame bank that accompanied its meanders; and when it disappeared among the hills, shades descending from the heights leaned towards its progress, and framed the distant point of light under which it was lost, as it turned aside to either hand of the blue horizon. Thus, dealing in none but the colours of nature, and catching its most favourable features, men saw a new creation opening before their eyes. The living landscape was chastened or polished, not transformed. Freedom was given to the forms of trees: they extended their branches unrestricted; and where any eminent oak, or master-beech, had escaped maiming, and survived the forest, bush and bramble was removed, and all its honours were restored to distinguish and shade the plain. Where the united plumage of an ancient wood extended wide its undulating canopy, and stood venerable in its darkness, Kent thinned the foremost ranks, and left but so many detached and scattered trees, as softened the approach of gloom, and blended a chequered light with the thus lengthened shadows of the remain-

ing columns. Succeeding artists have added new master-strokes to these touches; perhaps, improved or brought to perfection some that have been named. The introduction of foreign trees and plants, which we owe principally to Archibald D'Argyle, contributed essentially to the richness of colouring so peculiar to our modern landscape. The mixture of various greens, the contrast of forms between our forest-trees and the northern and West Indian firs and pines, are improvements more recent than Kent, or but little known to him. The weeping willow, and every florid shrub, each tree of delicate or bold leaf, are new tints in the composition of our gardens."

GARDENING, in the perfection to which it is now brought in Britain, is entitled to a place of considerable rank among the liberal arts. "It is," says Mr. Wheatley, "as superior to landscape-painting as a reality to a representation: it is an exertion of fancy; a subject for taste; and being realized now from the restraint of regularity, and enlarged beyond the purposes of domestic convenience, the most beautiful, the most simple, the most noble scenes of nature, are all within its province. For it is no longer confined to the spots from which it takes its name; but regulates also the disposition and embellishments of a park, a farm, a forest, &c. and the business of a gardener is to select and apply whatever is great, elegant, or characteristic, in any of them; to discover, or to shew, all the advantages of the place upon which he is employed; to supply its defects, to correct its faults, and improve its beauties." But though all these encomiums are justly due to gardening, upon the large scale of an ornamental garden, including a park, farm, forest, &c. yet our limits here require, that we treat on that part of gardening which regards usefulness and convenience more than ornament.

OF THE CHOICE OF GROUND FOR A GARDEN.

In the choice of a place proper for a garden, the most essential points to be considered are, the situation, the soil, the exposure, water, and prospect.

I. The situation ought to be such as is wholesome, and in a place neither too high nor too low; for if a garden be too high, it will be exposed to the winds, which are very prejudicial to trees; and if it be too low, the dampness, the vermin, and the venomous creatures that breed in ponds and marshy places, will add much to its insalubrity. The best situation is on the side of a hill, especially if the slope be easy, and almost imperceptible; if a good deal of level ground be near the house; and if it abound with springs of water; for, being sheltered from the fury of the winds and the violent heat of the sun, a temperate air will be enjoyed; and the water that descends from the top of the hill, either from springs or rain, will not only supply fountains, canals, and cascades for ornament, but, when it has performed its office, will water the adjacent valleys, and, if it be not allowed to stagnate, will render them fertile and wholesome.

II. A good soil is next to be considered; for it is scarce possible to make a fine garden in a bad soil. There are indeed methods of meliorating ground, but they are very expensive; and sometimes, when the expence has been bestowed of laying good earth three feet deep over the whole surface, a whole garden has been ruined, when the roots of the trees have reached the natural bottom. To judge of the quality of the soil, observe whether there be any heath, thistles, or such-like weeds, growing spontaneously in it; for they are certain signs that the ground is poor. Or if there be large trees growing thereabouts, observe whether they grow crooked, ill-shaped, and grubby; and if they be of a faded green, and full of moss, or infested with vermin; in all such cases, the place is to be rejected. But if it be covered with grass fit for pasture, the depth of the soil may be tried. To know this, dig holes in several places, six feet wide and four deep; and if there be three feet of good earth it will do very well, but less than two will not be sufficient. The quality of good ground is neither to be stony nor too hard to work; neither too dry, too moist, nor too sandy and light; nor too strong and clayey, which is the worst of all for gardens.

III. The next requisite is water; the want of which is one of the greatest inconveniences that can attend a garden, and will bring a certain mortality upon whatever is planted in it, especially in the greater droughts, that often happen in a hot and dry situation in summer; besides its usefulness in fine gardens for making fountains,

fountains, canals, cascades, &c. which are the greatest ornaments of a garden.

IV. The last thing to be considered, is the prospect of a fine country; and though this is not absolutely necessary, yet it is one of the most agreeable beauties of a fine garden: besides, if a garden be planted in a low place that has no kind of prospect, it will not only be disagreeable but unwholesome.

OF LAYING OUT AND PLANTING GARDENS.

Gardens are usually distinguished into Flower-Gardens, Fruit-Gardens, and Kitchen-Gardens. The first being designed for pleasure and ornament, should be placed in the most conspicuous part, that is, next to the back or front of the house; and the two latter, being designed for use, should be placed less in sight. But though the fruit and kitchen gardens are here mentioned as distinct, yet they are now usually united; as they equally require a good soil and exposure, and should both be placed out of the view of the house. In the laying out and planting of gardens, the beauties of nature should always be studied; for the nearer a garden approaches to nature, the longer it will please. According to Mr. Miller, the area of a handsome garden may take up 30 or 40 acres, but no more; and the following rules should be observed in the disposition of it. There ought always to be a descent of at least three steps from the house to the garden; this will render the house more dry and wholesome, and the prospect on entering the garden more extensive. The first thing that ought to present itself to view should be an open lawn of grass; which ought to be considerably broader than the front of the building; and if the depth be one-half more than the width, it will have a better effect: if on the sides of the lawn there are trees planted irregularly, by way of open groves, the regularity of the lawn will be broken, and the whole rendered more like nature. For the convenience of walking in damp weather, this lawn should be surrounded with a gravel-walk, on the outside of which should be borders three or four feet wide for flowers; and from the back of these the prospect will be agreeably terminated by a slope of ever-green shrubs; which, however, should never be suffered to exclude agreeable prospects, or the view of handsome buildings. These walks may lead through the different plantations, gently winding about in an easy natural manner; which will be more agreeable than either those long straight walks, too frequently seen in gardens, or those serpentine windings that are twisted about into so many short turns as to render it difficult to walk in them; and as no garden can be pleasing where there is a want of shade or shelter, these walks should lead as soon as possible into plantations, where persons may walk in private, and be sheltered from the wind. Narrow rivulets, which have a constant stream, if they are judiciously led about the garden, have a better effect than large stagnating ponds or canals so frequently made in large gardens. When wildernesses are intended, they should not be cut into stars and other ridiculous figures, nor formed into mazes or labyrinths, which in a great design appear trifling. In a word, the several parts of a garden should be diversified; but in places where the eye takes in the whole at once, the two sides should be always the same. In designs, the aim should be always at what is natural. The general disposition of a garden and of its parts ought to be accommodated to the different situations of the ground, to humour its inequalities, to proportion the number of sorts of trees and shrubs to each part, and to shut out from the view of the garden no objects that may become ornamental. But these extended views of the subject are not to our present purpose. A practical attention to a garden, is by some esteemed a degrading employment. It is true, indeed, that pastoral and agricultural manners, if we may form a judgement from the dignified descriptions of Virgil, are greatly degenerated. The employments of the shepherds and husbandmen are now become mean and sordid. The work of the garden is usually left to a peasant. Nor is it unreasonable to assign the labour, which wears without amusement, to those who are sufficiently amused by the prospect of their wages. But the operations of grafting, of inoculating, of pruning, of transplanting, are curious experiments in natural philosophy; and that they are pleasing as well as curious, those can testify who remember what they felt on seeing their attempts in these branches of practical gardening attended with success. Among the employments suitable to old age, Cicero has enumerated the superintendence of a

garden. It requires no great exertion of mind or body; and its satisfactions are of that kind which please without violent agitation. Its influence on health is an additional reason for an attention to it at an age when infirmities abound. But it is not the extensive garden alone that calls our attention, or yields us pleasure. The possessor of an acre, or a small portion, may receive a real pleasure, from observing the progress of vegetation, even in a plantation of culinary plants. A very limited tract, properly attended to, will furnish ample employment for an individual. Nor let it be thought a mean care; for the same hand that raised the cedar, formed the hyssop on the wall. Even the orchard, cultivated solely for advantage, exhibits beauties unequalled in shrubbery; nor can the greenhouse produce an appearance to excel the blossom of the apple and the almond. The kitchen-garden ought to be situated on one side of the house, near the stables, from whence the dung may be easily conveyed into it; and after having built the wall, borders should be made under them, which, according to Mr. Miller, ought to be eight or ten feet broad. Upon these borders, exposed to the south, many sorts of early plants may be sown; and upon those exposed to the north, may be sown some late crops, taking care not to plant any deep-rooting plants, especially beans and pease, too near the fruit-trees. Next proceed to divide the ground into quarters; the best figures for these are a square or an oblong, if the ground will admit of it; otherwise they may be of that shape which will be most advantageous. The size of these quarters should be proportioned to that of the garden; if too small, the ground will be lost in walks, and the quarters being inclosed by espaliers of fruit-trees, the plants will draw up slender, for want of a more open exposure. The walks should also be proportioned to the size of the ground; these in a small garden should be six feet broad, but in a large one ten, and on each side of the walk there should be allowed a border three or four feet wide between it and the espalier. In these borders may be sown small sallads, or any other herbs that do not take deep root or continue long; but they should not be sown or planted with the same plants two years together. In the quarter nearest to the stables, and best defended from the cold winds, should be the hot-beds, for early cucumbers, melons, &c. and to these there should be a passage from the stables, and a gate through which a small cart may enter. The most important points of general culture consist in well digging and manuring the soil, and giving a proper distance to each plant, according to their different growths: as also in keeping them clear from weeds: for which purpose, always observe to keep the dunghills free from them, otherwise their seeds will be constantly brought in and spread with the dung.

THE GARDENER'S CALENDAR.

Under this head we proceed to point out what is proper to be done in the different months of the year, in the Kitchen-Garden, Flower-Garden, Orchard, &c. It is necessary, however, to mention here, that the arrangement in the following Calendar was originally drawn up for the climate of England; but will suit those parts of Scotland where the climate is mild equally well, upon allowing a difference of ten or twelve days later for sowing or planting. Where the seasons are still more backward, a proportional allowance will be made by the judicious gardener, or practitioner in this pleasant art.

JANUARY.

KITCHEN-GARDEN. Cauliflower-plants under glasses and frames should be covered with pea-straw, or mats, to defend them from the frost. Celery and endive should be dug up as soon as the frost begins, for daily use, and the other covered with straw. Cucumbers for the first crop, to come in early in March, should now be sown. As soon as they are three or four days old put each into a small pot; and every week sow more to have plenty of plants. Dung should be wheeled into the kitchen-garden in frosty weather, when other work cannot be done. Ground lying vacant should be dug up, if omitted in October, and thrown up into ridges. Hotbeds and loam should be prepared for asparagus, cucumbers, and melons. Lettuces under glasses should be examined, and if they be killed, sow more on a hotbed. Mushroom-beds will require regular attendance, and frost and rain must be

kept out by dry straw and mats. Onions, to draw young, should be sown on a warm border. Peas under the south wall, for the first crop, should have the earth drawn up to them in a dry day, and sticks placed to them to defend them from the violence of the winds; and sow the second crop. Plant asparagus for the fourth crop. Beans for the second crop of mazagans. Beets, cabbages, carrots, parsneps for seed. Mint and potatoes on a hotbed. Onions for eschalions and seed. Radishes for the second crop sow in a warm situation, and the first crop on a hotbed. Small sallading, as cress, mustard, rape, radishes, sow every week on a hotbed. Sow carrots for the first crop, and the second of peas. Sow on hotbeds, carrots and cucumbers for the first crop. Cress, mustard, radish, and rape for sallads; sow likewise turneps.

FLOWER-GARDEN AND SHRUBBERY. Anemones which were planted in the autumn will require to be covered with pea-straw, rotten tan, or mats. Auricula and polyanthus seeds may now be sown in boxes or pots in mild weather. Auriculas should be sheltered from violent rains and frost by mats; and at the end of the month fresh earthed. Beds for bulbous roots which have not been planted in October or November, should be digged and thrown up into ridges, that they may be planted the first fine weather. Carnations must be sheltered from violent rains and frost by mats. Plant all sorts of bulbous roots, crocuses, as jonquils, narcissuses, polyanthus-narcissuses, snow-drops, tulips, &c. Plant flowering-shrubs which are hardy, and flower early, as almonds, double-flowering cherries, honey-suckles, lilacs, mezeoreons, roses, &c. Trenches should be cut to carry off the water, if it stand any where, after heavy rains.

FRUIT-GARDEN AND ORCHARD. Apple-trees should be pruned as soon as the violent frosts are over. Espaliers ought always to be repaired before the buds of the trees begin to open. The fruit-room should be often examined, to pick out all fruit which begins to decay; and nail mats before the windows to keep out the frost. Ground for planting should be prepared by digging the holes ready; and if wet, a cart-load of good loam should be brought for each standard-tree, and formed into a little hill before the tree be planted. Scrape off the moss from all fruit-trees. Orchards in general are much neglected, by not cutting out the dead wood and branches that cross each other. Pear-trees require pruning, both standards, espaliers, and against walls, as soon as the weather becomes mild. Prune currants, gooseberries, and raspberries in pots may be placed on hotbeds for forcing. Vines should not be pruned till towards the end of the month.

GREENHOUSE. Air may be given to the plants, if the weather be mild. Fire must be made if it freeze, and particularly when it begins to thaw, or if it be foggy weather to dry the house; for dampness is as prejudicial as cold. Succulent plants, such as aloes, ficoides, &c. should not have any water this month. Water for all sorts of plants should be the softest that can be got; rain-water is the best; the chillness should be taken off by letting it stand in the house some days before it is used; and this month it should be given very sparingly. Windows in frosty weather should be kept very close, by pasting strips of paper where the wind blows in; if the windows must be covered with mats, take them down in the day-time to admit the light.

FEBRUARY.

KITCHEN-GARDEN. Sow melons at the beginning of the month for the first crop, and when about three days old, plant each in a small pot. Plant mint in pots on a hotbed. Defend mushroom-beds from wet. Sow parsley for edgings, and some curled, very thin on a bed, to grow large for garnishing of dishes, and the large-rooted. Sow parsneps on ground digged very deep. Peas should be earthed in dry weather, and will require sticking. Sow marrowfats and other large sorts, and the third crop of hotspurs. Plant asparagus for forcing, for the last crop. Beans for a third crop: Windsors, for the first; Cauliflowers from under the glasses; endives for blanching and seed: eschalots, garlic, and rochambole; horse-radish, lettuces, from under glasses; leeks, onions, and parsley for seed; potatoes on hotbeds, for the first crop. Uncover radishes in mild weather, and put the straw on again at night. Sow beets, cabbages, carrots, cauliflowers, coleworts, fennel, leeks, lettuces, mustard, onions, parsley, parsneps, peas, radishes, spinach. Sow on hotbeds, cauliflowers, celery, cress, cucumbers, melons, mustard, radish, rape for sallads. Sow spinach, the first crop, and hoe the winter-crop

if it be too thick. Water should be carried away, if it stands after heavy rains, by cutting trenches.

FLOWER-GARDEN AND SHRUBBERY. Plant anemones and ranunculuses: box for edgings at the end of the month; bulbous and tuberous roots of all sorts; flowering shrubs and ornamental trees: forest-trees of all sorts, except evergreens. Shrubby should be digged over and raked smooth, to destroy the young weeds beginning to shoot; but the trees should first be pruned. Shrubs of all sorts should have the suckers taken off, and, if small, be planted in beds a foot asunder until they are stronger; and any sorts may now be planted. Sow at the end of the month hardy annuals and mignonette.

FRUIT-GARDEN AND ORCHARD. Apple and pear trees should be finished pruning the first mild weather. Plant cuttings of currants and gooseberries. Prepare grafts of apples and pears. Place hurdles against peaches, nectarines, and apricots, in the beginning of the month; they should be about two feet higher than the walls, that they may be set sloping; and must be fastened with stakes, and remain there till the fruit is set. Sow kernels of apples and pears, for stocks. Planting all sorts of fruit-trees should be finished early in the month, and the roots covered with mulch. Pruning wall-trees should be finished. Strawberries may be planted at the end of the month, and the old beds dressed; those on hotbeds must be frequently watered. Vines, finish pruning before they bleed. Wall-trees, as apricots, nectarines, peaches, plums, pears, should be finished pruning in the month, and those done in October must be examined, and the dead ends cut off.

GREENHOUSE. Admit air, very freely in mild weather. Earth the top of the pots, but first take out the old an inch deep. Fire must be made in foggy weather to dry the house. Leaves this month decay very fast; therefore they will require picking off almost every day, but especially from the geraniums. Myrtles, oranges, winter-cherries, and some others, water frequently, but not too much at a time. Succulent plants, as aloes, ficoides, &c. must not have any water given them in this month, for it will cause them to rot. Water the plants which require it frequently, but very sparingly; for too much moisture in the house will injure the plants. Windows may be opened for a few hours in the middle of the day, but should be shut again about two o'clock, or whenever it begins to be foggy.

MARCH.

KITCHEN-GARDEN. Alisanders sown in autumn, should be hoed to a foot asunder, and more seed sown. Aromatic shrubs and herbs on beds, weed and fresh earth, early in the month; sow and plant more of all sorts. Dress artichokes, and take the suckers off for a fresh plantation. Plant artichokes, asparagus, beans, cives, cucumbers, Jerusalem artichokes, lettuces, melons, mushrooms, potatoes, and tarragon. Plant aromatic herbs and shrubs; as balm, camomile, lavender, mint, pennyroyal, rosemary, rue, sage, savory, thyme, &c. Pot and sweet-herbs should now be sown. Slip pot-marjoram, savory, and thyme. Weed potatoes, and plant the principal crop. Sow radishes, the fourth crop, and rampions. Sow alisanders, angelica, asparagus, basil, beets, borage, broccole, broccoli, burnet, cabbages, capscums, carrots, cauliflowers, celery, celeriac, chardons, chervil, clary, corianders, cress, cucumbers, dill, fennel, hyssop, kidney-beans, leeks, lettuces, marjoram, marigolds, melons, mustard, nasturtiums, onions, parsley, parsneps, peas, purslane, radishes, rampions, salsify, savory, scorzonera, sea-kale, skirrets, sorrel, spinach, tarragon, thyme, tomatoes, turneps, water-cresses. Weed spinach, and sow the second crop. Turneps, sow the first crop. Sow water-cresses, in a moist place, or where it may be constantly supplied with waste water from the pump. Destroy weeds, while small, which will save future trouble.

FLOWER-GARDEN AND SHRUBBERY. Anemones and ranunculuses, if any remain unplanted, must not be deferred longer than the first mild day. Anemones in flower should be covered with mats in windy or rainy weather. Annual flowers of all the hardy sorts in the Catalogue at the end of the calendar may be sown about the middle of the month in small patches where they are to remain; hollow the earth out in the form of a basin, fifteen inches over, and an inch deep, and sow the seeds very thin all over it, and not a small patch in the middle, as is too frequently the custom. Box for edgings, in mild weather. Bulbous roots in beds should

should be covered with mats in rainy or stormy weather, and the earth stirred gently up with one's fingers to destroy the weeds. Carnations should be potted. Evergreen shrubs, and trees of all sorts, may be planted in mild weather; then cover the roots with turf turned downwards, moss, fern, pea-straw, or some such things, to keep the ground moist, which is better, and gives less trouble than watering. Plant flowering shrubs and forest-trees of all sorts, early in the month, and cover the roots. Mignonette, sown last month, should be transplanted, and more of it sown. Myrtles, winter-cherries, and other hardy greenhouse-plants, planted against walls, should have the mats rolled up in fine weather, and the dust washed off from the leaves, but covered again at night. Perennial and biennial flowers must be sown on beds, very thin, that they may be strong; those sown last year should be transplanted, and the old roots of the perennials divided. Plant annuals from the first hot-bed: Biennials and perennials from the seedbed: Box for edgings: Evergreens of all sorts: Perennials, by dividing their roots, and seedlings of last year's sowing: Shrubs and trees early in the month: Strawberries and thrift for edging. Shrubberies should be pruned early in the month: the suckers taken off, and planted a foot at least asunder, and the rows two feet apart; the ground hoed or digged, and then raked over, that it may appear neat and clean.

FRUIT-GARDEN AND ORCHARD. Apricot, nectarine, and peach-trees, should have hurdles placed before them, to defend the blossoms from hail: or else stick branches of yew, fern, or fir, amongst them, but hurdles are the best. Fig-trees which have mats nailed over them should have them taken away by degrees, towards the end of the month. Graft trees, and cut down the budded ones. Planting and pruning trees of all sorts should be finished at the beginning of the month. Strawberry-beds should now be attended to; hoe them and stir up the earth between them; then spread some very rotten dung and earth over them. Those on hotbeds want frequent watering, and the dead leaves should be constantly picked off, to let the sun come to the fruit. New plantations may now be made. Vines may now be layered; plant cuttings.

GREENHOUSE. Give air freely in the middle of the day, except the wind be very cold. Earth the tops of the pots, but take the old earth out an inch deep. Place geraniums near the windows to prevent their being drawn up weak. Myrtles, winter-cherries, and other hardy plants, will want fresh potting, and, if the weather be mild, may be taken out to make more room, but set them in a sheltered place at first. Sow kernels in pots, good strong seed, and if they are set an inch asunder, they will grow faster. Succulent plants may now have a little water, but not much at a time. Water the plants in the middle of the day, and only when the sun shines.

APRIL.

KITCHEN-GARDEN. April being the latest time for sowing the principal crops of the kitchen-garden, if any thing directed to be performed last month were omitted, or the weather would not permit, let it be done early in this. Aromatic herbs and shrubs of all the following sorts should now be planted, as balm, camomile, pennyroyal, peppermint, spearmint, tansey, lavender, rosemary, rue, sage, southernwood, wormwood, &c. Finish both sowing and planting asparagus early in the month. Let the beds be forked and raked smooth, and watered twice a week with drainings of a dunghill. Cut off every bud, however small; for, if they be left on, they weaken the others; this method is in general only practised by the London kitchen-gardeners. Never suffer any weeds to remain after they are in an inch high, for they weaken the asparagus very much. Beans in flower should have their tops cut off; and draw the stalks of the first crop close to the wall by strings, and earth them up. Plant the third crop of Windsors. Kale and brocoli should have the first crop pricked out, and the second sown. Cabbages of the early sort should have their leaves tied up to forward their cabbaging. Prick out from the seedbed the third crop of sugarloaf, the second of red, and the first of savoys. Pick out capsicums, from the seedbed, to prevent their growing weak, upon another hotbed. Weed carrots, thin the first crop, and sow the second to draw young. Search for caterpillars upon cabbages and apple-trees particularly. Sow cress and mustard, every week. Cucumber-beds must be attended to, and plenty of air given them, when mild; and, if the heat declines, fresh dung must be added to

the sides. Sow kidney-beans, the second crop, and the first of the scarlet-flowering. Tie up lettuces, to assist their cabbaging; those in beds should be thinned to a foot distance; others planted out, and the fourth crop sown very thin in an airy place. Melon-beds will require to be kept up to a good heat, and the second and third crop planted out. Thin Parsley for garnishing dishes, and leave those plants which have the best curled leaves. Sow the large-rooted. Earth up peas frequently, and stick them as soon as any tendrils appear. Sow the third crop of marrowfat. Plant beans and mushrooms.

FLOWER-GARDEN AND SHRUBBERY. Anemones in stormy weather will still require covering with mats. Annual flowers on hotbeds will require thinning, and some of the strongest must be planted into single pots. Hardy annuals, if not already sown as directed in March, should be deferred no longer, and sown very thin. Auriculas in bloom must be constantly attended to, and defended from violent winds, but yet have plenty of air in mild weather; the seedbeds will want frequent and gentle waterings. Balm of gilead may be sown or slipped, but the strongest plants will be raised from seed. Biennial and perennial flowers finish sowing early in the month. Bulbous-rooted flowers, which were planted in boxes or glasses, as soon as the flowers are decayed, should be planted in the ground, to strengthen the roots. Carnation-seed may now be sown, and stir up the earth frequently of those in pots. Crocus-leaves are by many persons cut off; but it greatly weakens the young roots, for the old ones decay, and new roots are formed every year; if they hang over in the walks, tie them up in a knot. Finish planting evergreen-trees and shrubs, and sow the seed. Plant annuals from the hotbeds into pots, and plunge them into another hotbed: Biennials and perennials on the borders: Myrtles, heaths, and other hardy greenhouse-plants: Hollies and quick for hedges: Strawberries and thrift for edgings: Shrubs and trees of all sorts early in the month: Tuberose in pots on a hotbed. Water seedling-heads of flowers, shrubs, and trees, often, but very little at a time. Shrubberies should be finished digging and raking, and frequently hoed when any weeds appear.

FRUIT-GARDEN AND ORCHARD. Apricots commonly growing in clusters require to be thinned three different times: as soon, therefore, as they are the size of a horse-bean, it is proper to begin. Budded fruit-trees, such as apricots, cherries, nectarines, peaches, plums, must be examined to pull off all the shoots which come from the stock. Caterpillars may now be readily found in their webs, but more particularly on apple-trees. Grafted fruit-trees, as apples, cherries, pears, must often be examined to put off the shoots below the grafts; and replace any clay which has cracked or fallen off. Apply hog's-dung to any fruit-trees which are blighted. Take away hurdles when the fruit is set. Finish planting and pruning nectarines and peaches. Planting and pruning should be entirely finished early in the month; and if any trees be removed so late, it should be those which have been planted in baskets and trained. Search for snails in the holes of walls. Finish dressing and planting strawberry-beds, but plant only strong runners of the last year.

GREENHOUSE. Give air, very freely, by keeping the windows open all day, except in storms of hail. American aloes may have water very often, and should be fresh potted. Earth the tops of all the pots, with the compost which each plant requires: and shift those which are in too small pots. Geraniums should be removed as near as possible to the windows, to prevent their being drawn up weak; branches which begin to rot must be cut off, and decayed leaves constantly pulled off. Inaroh-orange and lemon-trees. Constantly pull off decayed leaves from all plants, but especially the geraniums. Myrtles, if prevented from being set out last month, may be removed in this, but it should be in a sheltered place. Prune and fresh-pot any plants that may need it. Orange-trees must be fresh-potted after the myrtles are taken out; leaves which are mildewed must be cleaned with a sponge and water a little warm, and the stems well brushed.

MAY.

KITCHEN-GARDEN. Aromatic herbs and shrubs may still be sown and planted. Artichokes should have the young-shoots pulled off, lest they rob the principal one. Asparagus-beds ought to be frequently weeded, and in very dry weather watering them will be proper. Beans will require to have their tops cut off as they

they come into flower, and the earth drawn up to their stems. Prick out the second crop of kale, and be sure to have plenty of plants, for in all long frosty winters its utility is fully proved. Cabbages will often want hoeing and earthing up. Plant the second crop, and the first of red. Sow the fourth crop, and the second of savoys. Cabbage-turneps, turneprooted-cabbages, American and white Scotch cabbages, and Anjou boorecole, must now be sown; whether they are intended for feeding cattle, or for eating. They are most profitable when very large, therefore sow the seed very thin. Sow cress and mustard every week on a cool border; and hoe that which is intended for seed. Cucumbers for the fourth crop may be planted out, and let some be against walls, both for seed and superior flavour. Sow now in the open ground. If plants be attacked with black flies, fumigate them with tobacco-smoke. Endive, thin the first crop and sow the second. Eschallots, garlic, and rocambole, may have a few roots taken up for present use. Hoe or weed the beds of beets, carrots, leeks, lettuces, onions, parsley, parsnips, turneps, &c. and thin them before they are too much crowded. Sow kidney-beans the third crop of dwarfs, and the second of runners. Thin lettuces in beds, and then sow the fifth crop. Melons on the tan-bed must be thinned.

FLOWER-GARDEN AND SHRUBBERY. Bulbous roots, which flower early, as aconites, anemones, crocuses, irises, snow-drops, and several others, should be taken up as soon as the leaves are withered, and before they entirely disappear, for then they are more readily found. Those in boxes or glasses, which have done flowering, should be put into the ground to strengthen the roots. Carnations will require sticks to be placed to them as soon as they begin to spindle, and the earth should be often stirred up. Evergreen-shrubs and trees lately planted must be frequently watered, and they may also be layered. Weed, roll, and mow, the grass-walks often. Gravel-walks will require frequent rolling. Hyacinths, as soon as the leaves begin to decay, should be taken up, then laid on a ridge of earth with their leaves downwards, and covered with earth two or three inches thick, to harden and ripen the roots. Insects of various sorts, as earwigs, caterpillars, snails, &c. should be searched for and destroyed. Mignonette may be sown in the open ground, for a succession in the autumn. Myrtles, heaths, and other hardy greenhouse-plants against walls, will often require watering. Plant bulbous roots which have been forced, in boxes, or glasses, into the open ground, to strengthen the roots. Ranunculuses should be weeded, and the earth gently stirred with the fingers. Rose-trees infected with green flies or grubs must be constantly examined; wash off the flies with water, and pinch those leaves which have grubs in them with the finger and thumb. To have roses late in autumn, cut off every flower-bud which now appears, from two or three trees, and water them well for about ten days afterwards. Seeds of every sort of flowers which are ripe should be gathered.

FRUIT-GARDEN AND ORCHARD. Apricots should be thinned for the second time, and all foreright shoots pulled off. Blighted trees should have hog's dung spread over the border; then fork up the ground and water it well. Pull off curled leaves, water the trees all over, and strew tobacco-dust on the leaves; or fumigate them with tobacco-smoke, which will greatly help to destroy the insects. Examine budded trees often, and pull off improper shoots. Caterpillars must be searched for upon apple-trees, and destroyed. Disbud all the wall-trees, by pulling off buds which come out in improper places. Espalier-trees should be examined to disbud them and train in the shoots. Grafted trees should have the clay taken off, if properly united. Nectarines and peaches will require thinning for the first time, and the trees to be disbudded. Forced strawberries should have the dead leaves pulled off, and be frequently watered. Those which are beginning to flower, or have lately been planted, must be often watered in dry weather. It is not generally known that hantboys and Chili strawberries do not, like all other species, produce hermaphrodite flowers, but male and female flowers on separate plants; and persons ignorant of this fact, allege their hantboys are blind; whereas those flowers which turn black in the middle are male plants, and never will produce fruit. To make a plantation properly, let a person skilled in botany examine them when in flower; he will then easily distinguish them by the male stamina above a quarter of an inch high. Most of them should be pulled up, and the male ones marked with

a stick; for they cannot be distinguished when out of flower. The females indeed will produce fruit, but neither so large nor well flavoured, and often ill-shaped; and the seed will not grow, unless impregnated by the male flowers. In making a new plantation, do it in the following manner:

```

*   *   *   *   *   *
  m   *   m   *   m
*   *   *   *   *   *

```

The male plants may be transplanted when in flower, if covered with a flower-pot for a few days after; three males will do for every fourteen females.

GREENHOUSE. Air must be given freely except on cold nights. American aloes must be often watered, and placed near the windows. Take geraniums towards the end of the month, except those with variegated leaves. Turn myrtles which are small out of the pots, and plant them in a bed of light rich earth. Orange-trees must be fresh-potted, if not done last month; and as soon as the leaves of mulberry-trees are the size of a half-crown, it shews that the weather is settled, and they may safely be set out. Windows may be kept open all day, and, towards the end of the month, all night, to inure the plants by degrees to the open air.

JUNE.

KITCHEN-GARDEN. Plant the first crop of kale, and sow the third. Broccoli, plant the first, prick out the third, and sow the fourth crop. Cabbages, plant the third crop, prick out the fourth and sow the fifth. Red cabbages, plant the second crop, and sow the third. Savoys, plant the first, prick out the second, and sow the third. Cress and mustard intended to stand for seed, should now be hoed for the last time; the cress left at six inches distance, and the mustard at eight. Nail up or stick cucumbers against walls. Sow the sixth crop of lettuces in a cool place, and thin those for seed to a foot distant. Cover melons in frames with mats in the middle of the day, and lay pieces of broken earthen plates or dishes under the fruit. Sow the last marrowfat pease in a cool place. Plant lettuces and melons. Weed pot-herbs and sweet-herbs often, and gather for drying, just before they begin to flower; then tie them up in small bunches, and hang them across lines in a shady room to dry. Prick out broccoli, cabbages, cauliflowers, and celery. Sow turneps and turnep-radishes. Sow radishes, the seventh crop, and turnep-rooted, and black Spanish, in a cool place. Rape and coleseed may now be sown. Seeds of all sorts must be gathered as they ripen, and defended from birds.

FLOWER-GARDEN AND SHRUBBERY. Take up anemones before their leaves are quite withered, and they will be more readily found. Annuals from the hotbeds will require fresh potting, and may be placed in the open air if it be settled and warm, but will want frequent watering. Annuals on the borders should have the earth stirred up with a hoe, and be often watered, and more sown to flower in autumn, as described under last month. Biennials and perennials, transplant from the seedbeds. Hoe and rake borders of the flower-garden and shrubbery frequently. Box may be clipped, but always do it in moist weather. Bulbous-rooted flowers of every sort, whose leaves are nearly withered, should be taken up before the leaves entirely disappear, and put into shallow wooden boxes, as directed for hyacinths, as soon as dry. Carnations require to be examined frequently and tied up to the sticks. Search for earwigs. Evergreens may be clipped in moist weather. Myrtles, and other greenhouse-plants against walls, should be often watered, all fore-right shoots pulled off while small, and the others nailed to the walls with long narrow shreds of fine cloth. Plant out perennials and biennials from the seed-beds in showery weather; and, if the sun should be very hot soon after, cover each plant with a flower-pot, until they have taken root. Pinks may now be increased by making pipings or cuttings, but a glass must be placed over them. Plant out all annuals from the seed-beds and hot-beds: biennials and perennials from the seed-beds. Shrubs ought frequently to be looked over; all straggling branches should be cut off or tied up; and the grounds stirred with a Dutch hoe. Shrubs in pots may be set in pans, and watered often. Sow annuals, as described under last month, to flower in autumn, in any vacancies that may be on the borders of the shrubbery or flower-garden. Tulips should be taken up before their leaves are quite decayed, that they may be found more readily.

FRUIT-GARDEN, AND ORCHARD. Apple-trees in espaliers must be often examined; all fore-right shoots should be taken off while small, and the others regularly trained to their proper distances. Search for caterpillars. If the standard apple-trees be infected with caterpillars, light some damp straw, and with a fork direct the smoke through the tree, and they will soon be suffocated, and instantly drop down. Apricots must be thinned for the third and last time, and the shoots frequently nailed up. Blighted trees must be constantly attended to, as directed last month. Bud apricots, cherries, and peach trees. Nail up fig-trees with very strong shreds. Nail up every week shoots of wall-trees. Vines require constant attendance, in rubbing off improper buds, and nailing up the shoots. Water those trees frequently which are blighted: all newly planted trees in dry weather; and strawberries in flower.

GREENHOUSE. Air may now be given very freely in the greenhouse, and the windows may be kept open all night. Plant cuttings of various sorts, under bell or hand glasses, at the end of the month. Earth all the plants every month at top, if not shifted. It makes them look neater, and grow better. Geranium-seedlings sown in March will now require pricking out, and cuttings planted under glasses. Inarch jessamines, lemons, and oranges. Layer jessamines, oleanders, &c. Plant myrtle-cuttings at the end of the month under glasses, but never take them off till they have grown two inches. Orange-trees, if not taken out at the end of last month, will require it at the beginning of this. Clean well the leaves which are mildewed, or have insects on them, with a sponge and warm water. Inarching may now be performed.

JULY.

KITCHEN-GARDEN. Aromatic herbs, flowers, and shrubs, gathered last month, if hung on lines, will soon be dried. It is then better to strip off the leaves and flowers from the stalks, and put them into paper-bags, which will preserve their flavour better, and keep them free from dust. Continue to gather them before their flowers are too much opened. Asparagus if wished for in autumn, must be attended to at the beginning of this month; the stalks must be cut down, and, if it be dry weather, the beds must be very well watered with the draining from a dunghill. Next day fork them up lightly, and rake them smooth; if the weather continues dry, water them every night for a week, and in about eight or ten days they will be fit to cut. Plant the second crop of kale, prick out the third, and the first of Anjou. Plant out the third crop of broccoli, and prick out the fourth. Plant the fourth crop of cabbages, and prick out the fifth. Prick out the third crop of red cabbages. Plant the second crop of savoys, and prick out the third. Cabbage-turneps, &c. for cattle, prick out the first crop. Sow carrots to draw young, the third crop. Earth up, and often water, capsicums. Plant out the fourth crop of cauliflowers. Plant the second of celery, and prick out the fifth. Finish sowing coleseeds, coleworts, and rape. Prick out the second crop of coleworts. Stick cucumbers on the open ground, with branches of elm, or other sticks. Lay tiles on endive, or tie up the first crop; plant the second, thin the third, and sow the fourth very thin. Take up some eschalots and garlic for present use. Sow finocchio, the fourth crop. Sow kidney-beans, on a south border, the fifth and last crop. Still plant lavender and rosemary cuttings. Plant red cabbages, rosemary, and savoys. Gather pot-herbs and sweet herbs for drying; and, as soon as dried, strip off the leaves, and put them into paper-bags.

FLOWER-GARDEN AND SHRUBBERY. Seeds nearly ripe must be watched and gathered, else many sorts will be lost. Annuals, to flower late in autumn, may still be sown. Auriculas and polyanthus from the seedbed should be transplanted upon a shady border, and, if possible, in rainy weather. Finish cutting box and evergreen shrubs. Bud the curious sorts of jessamines, roses, &c. Mignonette should now be sown to flower in winter, and more put into pots. Myrtles, and other greenhouse-plants against walls, will require frequent nailing and watering. Finish planting perennials and biennials from the seed-beds. Pinks, finish making pipeings or cuttings. Plant auricula and polyanthus seedlings: biennial and perennial seedlings: cuttings of scarlet lychnis and pinks: evergreens, if the weather be rainy: mignonette into pots: offsets of lilies: offsets of autumnal-flowering bulbs: pipeings of carnations and pinks: saffron-crocus. Ranunculuses must be taken up, and laid in the shade to dry; then well cleaned from earth, and

laid in shallow boxes, or put into paper-boxes. Finish layering and budding rose-trees. Seedling-trees, shrubs, and flowers, must be properly shaded and watered. Seeds now begin to ripen very fast; therefore must be constantly attended to, and gathered. Shrubberies will require frequent attention in pruning of hoeing.

GARDEN-FRUIT AND ORCHARD. Destroy ants, flies, and wasps, as soon as they appear, by hanging bottles half filled with sugar, or honey and water. Often look over apricot-trees; pull off all fore-right shoots, and nail those which are to remain. Attend to blighted trees, and water the borders of en. Budding of apricots, cherries, and peaches, finish. Currants intended to be preserved till autumn, should now be covered with mats. Often examine espalier-trees, and train in the shoots. Fig-trees require nailing up as they shoot, with strong nails and long shreds. Fruit should be gathered in the morning, as soon as the sun has dried the dew from it, and before it is heated, and then laid in a cool room. Destroy insects of all sorts. Water strawberries in flower constantly in dry weather, and pull off decayed leaves. Tie up the fruit of the hant-boys and other large sorts to sticks. Cut off all runners after the first, and these should be planted out as soon as some rain falls. Vines must be very often attended to, to nail up the shoots; and pull off all improper buds. Wall-trees require constant attention, to nail up and water in very dry weather.

GREENHOUSE. African aloes, and other succulent greenhouse-plants, may now be set out in the open air. Cuttings of asters, geraniums, grevias, myrtles, &c. should now be planted under bell or hand glasses, which should not be taken off until they have grown an inch. Earth the tops of all the pots, first taking a little out. Plant geranium-cuttings, and prick out the seedlings before they are too thick. Those with variegated leaves do best in alcoves or under a little shelter. Paint and white-wash the greenhouse. In arching and layering various sorts may still be performed. Plant stocks, when four inches high, in separate pots. Pans should be placed under all the pots, as it is better for the plants, and saves much trouble in watering. Shade, water, and prick out, seedling plants. Succulent plants, as aloes, cereuses, ficoides, and Indian figs, torch-thistles, &c. may now be set abroad.

AUGUST.

KITCHEN-GARDEN. Sow alsanders, angelica, and chervil. Sow corn-sallad on beds. Cucumbers for pickling, either large or small, to have them fine, should now be gathered; and they will be free from spots, and save much trouble in greenening. Lettuces, for standing through the winter, and for forcing, must now be sown very thin at three different times in the month: and plant out those last sown on a south border. Melons, in rainy weather, must be defended from wet by putting hand-glasses over them; and sticks placed for the pickling melons to run up. Prepare mushroom-beds, by having dung and spawn ready for the next month. Onions must be frequently turned, that they may be well dried. Sow the second crop of Welsh onions. Gather peppermint for distilling, as soon as it begins to flower. Sow some hotspur-peas, on a south border for the fifth and last crop. Plant celery, endive, leeks, and lettuce. Prick out Anjou, Brussels boorcele, cabbage-turneps, and turnep-rooted cabbages. Sow radishes, the ninth and last crop. Seeds, nearly ripe, must be guarded from birds, particularly radish-seeds. Sow cress, fennel, mustard, and sorrel. Sow the second crop of prickly broad-cast spinach, and then, at spring, hoe it into beds four feet wide, with paths of eighteen inches between the beds.

FLOWER-GARDEN, AND SHRUBBERY. Plant bulbous roots, that flower in autumn, early in the month. Bulbous roots of all sorts should have their offsets planted at the end of the month. Take off carnations' layers, and plant out the pipings from under the glasses. Finish the clipping of evergreen trees and shrubs. Grass-walks and lawns require frequent mowing. Gravel-walks must be weeded and rolled. Take up lilies, if their leaves be decayed; but the offsets must be planted again directly. Plant mignonette in pots to flower in winter, and place them under a south wall. Myrtles and greenhouse-plants against walls must be pruned and nailed, and constantly watered.

FRUIT-GARDEN, AND ORCHARD. Destroy ants, flies, and wasps, by supplying fresh bottles of sugar, or honey and water. Apple-trees on espaliers will require frequent examining. Budding of all trees finish, and pull off buds and shoots from the stocks.

Currants

Currants intended to be preserved, finish covering with mats. Nail up every week the fruit-trees. Nail up nectarines and peaches frequently. Attend to pear and plum-trees, both on walls and against espaliers, constantly. Transplant strawberry-runners, if rooted, in rainy weather, and cut off all the others as they shoot.

GREENHOUSE. Take off the offsets of aloes, both African and American, and plant them in separate pots. Often water the cuttings of myrtles, geraniums, &c. Earth the tops of all the pots. Water geraniums and myrtles constantly, but pour on the water gently. Oranges, still bud till the middle of the month. Prune any which require it, as this is the season of their shooting.

SEPTEMBER.

KITCHEN-GARDEN. Sow cress and mustard every week; and at the end of the month under glasses. Cucumbers for pickling should be finished gathering; which will shew the advantage of sticking them, and pickling early. Plant out a little of the fourth crop of endive to thin it, and give the rest more room. Tie up some to blanch. Eschalots, garlic, and rocambole, should have the offsets and small roots planted. Lettuces must be thinned early in the seed-bed, if sown thick, and pricked out on a south border to about four or five inches asunder. Melons for pickling will now be fit to gather. Make mushroom-beds at the beginning of the month. Gather nasturtiums for pickling. Finish sowing onions, early in the month, the second crop of Welsh. Weed those sown last month before the weeds are high. Plant water-cresses. Pick out cabbages, cauliflowers, and lettuces. Gather seeds constantly as they ripen. Sow cress, mustard, turneps, and water-cresses. Finish sowing spinach for spring use, and hoe that sown last month. Plant tarragon-roots. Hoe and thin turneps, turnep-radishes, and black Spanish radishes. Water in dry weather any crops lately planted out.

FLOWER-GARDEN, AND SHRUBBERY. Plant anemones, single-flowered, at the end of the month to flower early. Annuals in pots must be frequently watered to ripen the seeds. Remove auriculas, that they may have the morning-sun, and finish slipping them. Balsams, cockscombs, egg-plants, or other curious annuals in pots, which are wished to raise seeds from, must be placed under shelter in an alcove, greenhouse, or room, fronting the south, and then the seeds will ripen. Prepare beds for planting bulbous roots, early in the month. Plant box for edgings, at the beginning of the month, or as soon as any rain falls. Plant bulbous roots of all sorts, early in the month; but the offsets and lilies, and crown-imperials first. Plant evergreens at the end of the month, if the ground be moist. Grass walks may now be repaired; or new ones made. Weed and roll gravel-walks often. Plant hyacinths, jonquils, lilies, narcissuses, polyanthus-narcissuses, &c. at the end of the month. Plant laurel-cuttings, in the shade. Layer laurustinuses and other shrubs. Take up lilies which flower late, as soon as their leaves are decayed, but plant the offsets again directly, and all other sorts of lilies. Place mignonette in pots, under shelter. Myrtles and greenhouse-plants against walls must be constantly watered in dry weather. Plant out perennial seedlings, and divide the old roots. Plant box for edgings, evergreens, crown-imperials, and lilies, early in the month; cuttings of laurel, honeysuckles, jessamines, shrubs, and trees, of all sorts; but not until after there has been some rain. Strawberries and thrift for edgings. Gather seeds in the middle of the day.

FRUIT-GARDEN, AND ORCHARD. Destroy ants, flies, wasps, and insects of all sorts, constantly. Sow cherry-kernels on beds. Plant currant and gooseberry cuttings and trees. Nail up fig-trees frequently with strong shreds. Attend to the fruit-room, and pick out the rotten pears, or any other sorts which begin to decay. Put grapes into bags of crape, gauze, or paper. Plant currants, gooseberries, raspberries, strawberries. Strawberries should be planted early in the month, and then they will be well rooted before the frost begins. Dress the beds, and plant some strong roots in pots to force.

GREENHOUSE. Remove aloes into the greenhouse in the beginning of the month, but leave out the American ones to the end. Plant cuttings and seedlings in separate pots, and earth the tops of all the pots. Set in geraniums with variegated leaves, early in the month, and leave off watering the leaves. Take myrtles out of the ground, and pot them. Fresh earth orange-trees, thin the fruit, or most of it will fall off, and take them into the house at the

end of the month. Take in succulent plants of all sorts, early in the month, and give them very little water. Water in the morning, and keep the windows open all night; leave off watering the geraniums over the leaves.

OCTOBER.

KITCHEN-GARDEN. Cut down asparagus-stalks, hoe the weeds, and spread earth from the paths on them, but first a little rotten dung. Prepare hotbeds, for forcing, and plant three-year old plants for the first crop. Beans, the early mazagan, must be planted on a south border, for the first crop. Plant out Anjou boorcole, the second crop, early in the month; and hoe the ground around the others. Plant out broccoli, the rest of the fourth crop. Plant out half the cabbages, sown in August, of the early sorts, in a warm situation. Plant cabbage-turneps, early in the month, and earth up the others. Finish hoeing carrots, sown in July. Attend to cauliflowers, beginning to flower, by breaking down the leaves. Those intended for glasses will want planting out; let there be six to each glass, and the rest in a frame, or under a south wall. Plant out celery, the fifth and last crop, and earth up the second to blanch. Finish planting coleworts. Sow cress, mustard, and radish, under glasses, and on a hotbed at the end of the month. Tie up endive, to blanch, or lay files on it, and plant more. Plant eschalots, garlic, and rocambole. Throw up vacant ground into ridges. Sow peas, the early hotspurs, on a south border near the wall, for a first crop. Plant on hotbeds asparagus for the first crop, and lettuces and mint.

FLOWER-GARDEN, AND SHRUBBERY. Remove auriculas and carnations into shelter, and in wet weather cover them with mats. Balsams, cockscombs, egg-plants, &c. intended to raise seed from, must be constantly attended to, to hasten the ripening of the seed. Turn over beds and composts for bulbous roots, frequently. Finish planting box for edgings, early in the month. Plant bulbous roots for forcing, in pots or boxes, and finish planting all others before the rain sets in. Plant crocuses, aconites, snow-drops, and any bulbous roots which flower early in the spring, at the beginning of the month. Plant evergreens of all sorts, early in the month. Plant bulbous roots early in the month; as aconites, amaryllises, corn-flags, crown-imperials, daffodils, garlic molly, irises, martagons, pancratiums, ranunculuses, snow drops, star of Bethlehem, tulips, &c. Plant also perennials at the beginning of the month: shrubs and trees of all sorts: strawberries and thrift for edgings: place seedlings in pots, under a south wall in the ground; and weed and earth seedlings in beds. Gather seeds in the middle of the day.

FRUIT-GARDEN, AND ORCHARD. Gather apples and pears in the middle of fine dry days. Plant apple-trees at the end of the month. Plant currants, gooseberries, and raspberries. Examine grapes in bags, to see that they are not mouldy or decayed. Gather nectarines and peaches, in the middle of the day. Orchards or fruit-trees intended to be planted, should have the ground prepared, and the holes digged some weeks before-hand; if the soil be very good, some loam and rotten dung should be mixed together, and the trees planted in it. If the orchard be wet, bring a cart-load of earth at least for each tree: form the earth into a little hill, about a foot high, and plant the tree upon it, but dig up the turf first a foot deep in a circle of four or five feet over. Gather peaches in the middle of the day, and, if not ripe, lay them in the sun for a few days in a window; they are much improved by roasting gently like apples, and eating them with sugar and wine. Plant peach-trees, at the end of the month. Plant fruit-trees of all sorts. Prune all sorts of wall-trees, but sweep off all the leaves first with a birch broom. Finish dressing strawberry-beds, and water the alpine frequently under the frames. Vines in pots should be transplanted; make the holes ready, pour water into them, and then gently turn them out of the pot, or place the pot in the hole and break it, and then the roots cannot be disturbed, and you will have fruit the next year. Finish pruning and planting wall-trees, early in the month.

GREENHOUSE. Give air very freely in the day-time, and leave some of the windows open at night until the end of the month. Earth the tops of the pots. Take in geraniums early in this month, if not done the last; water them sparingly, or they will begin to shoot afresh, and pick off constantly all decayed leaves. Clean leaves well before the plants are set in order, and pick off dead ones.

ones. Take in myrtles towards the end of the month. Orange-trees should not remain out this month; examine the leaves before setting them in, for insects, which fasten themselves underneath, and pick them off; if any leaves be mildewed, wash them with warm water and a sponge. Water succulent plants sparingly. Water myrtles, orange-trees, winter-cherries, and all woody plants often. Open the windows every fine day, but keep them shut in foggy weather.

NOVEMBER.

KITCHEN-GARDEN. Finish planting beans for the first crop. Plant beets, cabbages, and carrots, for seed. Take up carrots and lay them in sand. Give some air to cauliflowers under glasses and frames, in the middle of fine days. Earth up celery, when dry, to blanch. Sow cress, mustard, and radishes, on hotbeds. Prepare hotbeds for forcing asparagus and lettuces. Sow early short-topped radishes, and spread wheaten straw over the beds.

FLOWER-GARDEN, AND SHRUBBERY. Bulbous roots, intended for blowing in water early, may now be placed on the glasses, and let all others be finished planting at the beginning of the month. Those in pots or boxes must be frequently watered, and placed as much in the sun and light as possible; for in the shade they will draw up weak. Composts wanted for flowers in spring should now be collected; such as loam, sand, willow-earth, rotten tan, dung, &c. Let them be laid in dry sunny places, and be frequently turned over, but by no means in cold wet places. Plant early in the month all bulbous roots; particularly those for forcing. All sorts of shrubs and trees should be finished planting early in the month; and long litter, straw, or turf, turned downwards, should be laid over the roots to keep out the frost.

FRUIT-GARDEN, AND ORCHARD. Finish any thing ordered last month, that has been omitted, early in this. Place strawberries in pots for forcing, under frames; and attend to the alpine. Finish the pruning and planting of wall-trees.

GREENHOUSE. Earth the tops of any of the pots, when any mould appears on them. Constantly pick off all decayed leaves, as they corrupt the air of the house very much. Succulent plants, as aloes, ficoides, &c. will require but very little water; large aloes the most. Water woody plants often, but give them only little at a time; as dampness is more prejudicial in a greenhouse than cold.

DECEMBER.

KITCHEN-GARDEN. Asparagus must be planted for the third crop, and give it both light and air to colour it. If the beds be not warm enough, line them with fresh dung. Boorcole, broccoli, and cabbages, must be well earthed up, to keep them upright, and all decayed leaves picked off. Cauliflower-plants must have air while the weather is mild, and pick off dead leaves. Earth up celery when dry, for blanching. Sow cress, mustard, and radishes, on hotbeds every week. Weed and turn over dunghills in frosty weather. Tie up endive for blanching. Hotbeds must be attended to, and plenty of hot dung and loam provided for cucumbers and melons. Lettuces under glasses must have air given them in the middle of mild days.

FLOWER-GARDEN, AND SHRUBBERY. Examine auriculas frequently, and pick off all decayed leaves. Carnations in pots should be plunged into the ground; but, if ashes or sand be put between the pots, it will keep them dryer than earth. Shrubs and trees may still be pruned; and long litter, &c. laid over the roots of those lately planted. Trenches and drains should be made wherever the water stands.

FRUIT-GARDEN, AND ORCHARD. Examine apples and pears in the fruit-room; pick out such as appear the soundest of the best sorts, and wrap each in a piece of paper. This will cause them to keep several weeks longer. Repair espaliers; prune the trees; spread some rotten dung on the border, and fork it in. Finish pruning fig-trees. Guard the fruit-room from frost, but give it some air, when the weather is not very damp nor frosty.

GREENHOUSE. Air must be given whenever the weather is mild, and will permit it. Earth the tops of the pots, but first take out a little of the old. Frost must be guarded against, by keeping the doors and windows close, when it begins to freeze. Constantly pick off decayed leaves. Myrtles and other greenhouse-plants against walls will require to have mats placed before them, and, in

the middle of fine days, before the frost is set in, rolled up, but let down again at night. Water those plants which require it very sparingly. Open the windows for three or four hours in the middle of the day.

A TABLE SHEWING THE NUMBER OF CROPS REQUIRED OF EACH SORT OF VEGETABLES, TO HAVE A REGULAR SUCCESSION THROUGH THE YEAR; WITH THE TIME OF SOWING AND PLANTING.

KITCHEN-GARDEN PLANTS, SEEDS, and ROOTS.

	No. of Crops.	Time of Sowing, &c.
Alisander.....	2	Mar. Aug.
Angelica.....	2	Mar. Aug.
Artichoke.....	1	Mar. or Apr.

Turnep-radish.....	2	June, July
Water-cress.....	2	Mar. Sept.

CATALOGUE OF FLOWERS, SHRUBS, AND TREES, USUALLY CULTIVATED.

I. TENDER ANNUAL FLOWERS.

To be sown on a strong hotbed the last week in February, or first in March, transplanted afterwards upon another at four inches distance; then planted in small pots in May; afterwards in larger, and at the end of June placed in the open air.

- | | |
|-------------------------|---------------------|
| 1. Amaranths. | 6. Humble plant. |
| 2. Balsams. | 7. Ice-plant. |
| 3. Cockscombs | 8. Sensitive plant. |
| 4. Egg-plants | 9. Stramoniums. |
| 5. Glocester amaranths. | |

II. ANNUAL FLOWERS.

To be sown on a moderate hotbed in March or April, transplanted afterwards before they are too thick, in rich light earth, and covered with mats; and in a month or six weeks into pots, or borders of the flower-garden.

- | | |
|----------------------------|---------------------|
| 1. African marygold. | 7. Chrysanthemum. |
| 2. Browallia, blue. | 8. French marygold. |
| 3. Capsicum. | 9. Marvel of Peru. |
| 4. Cape-marygold | 10. Mignonette. |
| 5. Chinese aster. | 11. Nolana. |
| 6. Chinese or Indian pink. | 12. Palma Christi. |

- | | |
|-----------------------|-------------|
| 13. Stock Julyflower. | 15. Zinnia. |
| 14. Sultan, yellow. | |

In sowing them, fix numbers to them, corresponding with these, to distinguish each sort when they appear.

III. HARDY ANNUAL FLOWERS.

To be sown in March or April on the borders of the flower-garden. Those marked thus †, being very hardy, may be sown in the beginning of February, to flower early. Hollow the earth out in form of a little bason, about a foot over, and two inches deep; draw a circle near the edge half an inch deep, and drop a few seeds in it; thin them soon after they appear, and leave them at six inches distance, but the large sorts wider. In dry weather, they will want frequent watering. Gather the seeds as they ripen, and you may save the expence of buying any in another season.

- | | |
|---------------------------|------------------------------------|
| 1. Adonis flower†. | 23. Mallow. |
| 2. Alkekengi. | 24. Mignonette. |
| 3. Alysson. | 25. Nasturtium†. |
| 4. Amaranth. | 26. Nigella, or devil in a bush†. |
| 5. Amethystea. | 27. Pansey, or hearts-ease. |
| 6. Balm, Moldavian. | 28. Peas, sweet-scented†. |
| 7. Belvidere. | 29. Persicaria.† |
| 8. Candy tuft†. | 30. Poppy†. |
| 9. Catchfly, Lobel's†. | 31. Safflower, or bastard saffron. |
| 10. Caterpillar trefoil. | 32. Snail-trefoil. |
| 11. Clary, red and white. | 33. Snap-dragon. |
| 12. Convolvulus. | 34. Stock July-flower†. |
| 13. Cornbottle†. | 35. Sunflower. |
| 14. Cucumber, spurting. | 36. Sweet sultan. |
| 15. Fumatory, yellow. | 37. Tobacco. |
| 16. Hedgehog trefoil. | 38. Venus's looking-glass†. |
| 17. Hone, wort. | 39. Venus's navelwort. |
| 18. Indian corn. | 40. Xeranthemum. |
| 19. Ketmia. | |
| 20. Larkspur†. | |
| 21. Lavatera. | |
| 22. Lupine. | |

In July, sow again annual stock, candy-tuft, convolvulus minor, cornbottles, Lobel's catchfly, and yellow lupines, and they will flower until the frost kills them.

IV. BIENNIAL FLOWERS.

To be sown in March or April in beds very thin; as soon as the plants touch one another, thin them, and leave them at four or six inches asunder; those drawn out, plant at the same distance. In July transplant them all upon beds, at eight inches asunder; there to remain till the end of September, when they must be planted upon the borders of the flower-garden, and they will produce their flowers the next summer, after which they will perfect their seeds and die.

- | | |
|---------------------------|--------------------------|
| 1. Canterbury bell. | 7. Poppy, yellow-horned. |
| 2. Colutea, Ethiopian. | 8. Rocket. |
| 3. French honeysuckle. | 9. Scabious. |
| 4. Globe-thistle. | 10. Stock July-flower. |
| 5. Honesty, or moon-wort. | 11. Sweet-william. |
| 6. Mallow-tree. | 12. Tree-primrose. |
| | 13. Wall-flower. |

V. PERENNIAL FLOWERS.

Which, if sown in the same manner as the biennials, and transplanted into the borders of the flower garden, will continue for several years.

- | | |
|------------------|-----------------------|
| 1. Alysson. | 11. Ox-eye daisy. |
| 2. Auricula. | 12. Pea, everlasting. |
| 3. Bee-larkspur. | 13. Pinks. |
| 4. Campanula. | 14. Polyanthus. |
| 5. Carnation. | 15. Rhubarb. |
| 6. Columbine | 16. Rose-campion. |
| 7. Flax. | 17. Snap-dragon. |
| 8. Fox-glove. | 18. Valerian. |
| 9. Hawk-weed. | 19. Greek valerian. |
| 10. Hollyhock. | |

VI. PERENNIAL

VI. PERENNIAL FLOWERS.

Which are propagated by dividing their roots in spring, in March or April; or in the autumn in September.

- | | |
|------------------------|-------------------------------|
| 1. Adonis flower | 45. Lychnis |
| 2. Anemone | 46. Lychnidea |
| 3. Asphodel | 47. Madwort |
| 4. Asters | 48. Marsh Marygold |
| 5. Bachelors buttons | 49. Meadow-sweet |
| 6. Bean-caper | 50. Milfoil |
| 7. Bears-breech | 51. Milk-vetch |
| 8. Borage | 52. Mint |
| 9. Bugloss | 53. Moth-mullen |
| 10. Campanula | 54. Navelwort |
| 11. Campion | 55. Peony |
| 12. Cardinal-flower | 56. Pilewort |
| 13. Christmas rose | 57. Plantain |
| 14. Cowslip | 58. Primrose |
| 15. Cranesbill | 59. Ragged Robin |
| 16. Crowfoot | 60. Ranunculus |
| 17. Daisies | 61. Reed |
| 18. Dog-tooth violet | 62. Rhubarb |
| 19. Dragons | 63. Saxifrage |
| 20. Dropwort | 64. Skullcap |
| 21. Eternal flower | 65. Sneezewort |
| 22. Fennel-giant | 66. Side-saddle-flower |
| 23. Feverfew | 67. Soapwort |
| 24. Flag | 68. Solomon's seal |
| 25. Fox-glove | 69. Spiderwort |
| 26. Fraxinella | 70. Spurge |
| 27. Fumatory | 71. Stonecrop |
| 28. Garlic | 72. Sunflower |
| 29. Gentianella | 73. Swallow-wort |
| 30. Golden-locks | 74. Thrift |
| 31. Golden rod | 75. Throatwort |
| 32. Greek valerian | 76. Toadflax |
| 33. Hellebore | 77. True love |
| 34. Hepatica | 78. Valerian |
| 35. Herb bennet | 79. Vervain |
| 36. Houseleek | 80. Veronica |
| 37. Ladies mantle | 81. Violet |
| 38. Ladies slipper | 82. Viper's bugloss |
| 39. Ladies smock | 83. Wake-robin |
| 40. Lily of the valley | 84. Willow-herb |
| 41. Lion's tail | 85. Wolfsbane |
| 42. London pride | 86. Wormwood and some others; |
| 43. Loose-strife | but with very little beauty |
| 44. Lupine | to recommend them. |

VII. BULBOUS AND TUBEROUS-ROOTED FLOWERS.

- | | |
|-------------------|--------------------------|
| 1. Aconites | 13. Iris |
| 2. Amaryllis | 14. Lily |
| 3. Anemone | 15. Martagon |
| 4. Bulbocodium | 16. Narcissus |
| 5. Cornflags | 17. Pancratiums |
| 6. Crocuses | 18. Polyanthus Narcissus |
| 7. Crown Imperial | 19. Ranunculus |
| 8. Cyclamen | 20. Sisyrinchium |
| 9. Daffodil | 21. Snowdrop |
| 10. Garlic Moly | 22. Star of Bethlehem |
| 11. Hyacinth | 23. Tuberose |
| 12. Jonquil | 24. Tulips |

To be taken up in April, May, and June, as soon as their leaves are withered, and planted again in September or October, but their offsets in August. The ranunculuses and anemones not to be planted till February. The seed to be sown in February, in boxes.

VIII. BULBOUS-ROOTED FLOWERS.

- | | |
|--------------|---------------------|
| 1. Amaryllis | 5. Daffodil, sea |
| 2. Colchicum | 6. Lily, Belladonna |
| 3. Crocus | 7. — Guernsey |
| 4. Cyclamen | 8. Saffron |

These flower in autumn. They require to be planted in Au-

gust, and to be taken up in April or May, as soon as their leaves are decayed; but their offsets in July.

IX. DECIDUOUS FLOWERING SHRUBS AND ORNAMENTAL TREES.

To be planted in March, April, September, and October.

- | | |
|---------------------------------|-----------------------------------|
| 1. Acacia, rose-flowering. | 37. Jesuits-bark Tree, false. |
| 2. Almond-tree. | 38. Indigo, Bastard. |
| 3. Allspice. | 39. Ironwood Tree. |
| 4. Althæa. | 40. Judas Tree. |
| 5. Ash, mountain. | 41. Kidney-bean Tree. |
| 6. Annona, or papaw. | 42. Laburnum. |
| 7. Azalea. | 43. Lac, or Varnish Tree. |
| 8. Berberry-tree. | 44. Leatherwood. |
| 9. Bigonia or Trumpet-flower. | 45. Lilacs. |
| 10. Bladder-sena. | 46. Mezerion. |
| 11. Bramble. | 47. Nightshade. |
| 12. Buckthorn. | 48. Olive Tree, wild. |
| 13. Caragana. | 49. Passion Flower. |
| 14. Cassioberry-bush. | 50. Peach Trees. |
| 15. Catalpa, or Trumpet-flower. | 51. Periploca, or Virginian Silk. |
| 16. Ceanothus. | 52. Plum Trees. |
| 17. Cephalanthus. | 53. Poison Trees. |
| 18. Cherry Tree. | 54. Pomegranate Tree. |
| 19. Cinquefoil, shrubby. | 55. Privet. |
| 20. Clethra. | 56. Raspberry. |
| 21. Cornel. | 57. Restharrow. |
| 22. Crab Tree. | 58. Rose Tree, 80 varieties. |
| 23. Cytisus. | 59. St. Peter's Wort. |
| 24. Diervilla. | 60. Sassafras. |
| 25. Dogwood. | 61. Service Tree. |
| 26. Fothergilla. | 62. Snowdrop, or Fringe Tree. |
| 27. Gingo, or Maidenhair Tree. | 63. Spindle Tree. |
| 28. Gueldres Rose. | 64. Spiræa. |
| 29. Halesia. | 65. Sumach. |
| 30. Hamamelis. | 66. Syringa. |
| 31. Hawthorn. | 67. Tamarisk. |
| 32. Hickory Nut. | 68. Tea Tree. |
| 33. Honeysuckle. | 69. Toothach Tree. |
| 34. Honeysuckle, upright. | 70. Traveller's Joy. |
| 35. Hypericum. | 71. Tupelo Tree. |
| 36. Jasmin. | 72. Viburnum. |
| | 73. Weeping Willow. |

X. DECIDUOUS FOREST TREES.

To be planted from the middle of February till the beginning of April, and from September till December.

- | | |
|---------------|--------------------|
| 1. Acacia. | 13. Horse-Chesnut. |
| 2. Alder. | 14. Larch. |
| 3. Ash. | 15. Lime. |
| 4. Beech. | 16. Magnolia. |
| 5. Birch. | 17. Maple. |
| 6. Chesnut. | 18. Nettle Tree. |
| 7. Crab Tree. | 19. Oak. |
| 8. Cypress. | 20. Plane. |
| 9. Elder. | 21. Poplar. |
| 10. Elm. | 22. Tulip Tree. |
| 11. Hickory. | 23. Walnut. |
| 12. Hornbeam. | 24. Willow. |

XI. EVERGREEN FLOWERING SHRUBS AND ORNAMENTAL TREES.

To be planted in March, April, September, and October.

- | | |
|------------------------------------|-------------------------------|
| 1. Alaternus. | 10. Cistus, or Rock-rose. |
| 2. Andromeda. | 11. Crab Tree. |
| 3. Arbor Vitæ. | 12. Cytisus, Hairy Evergreen. |
| 4. Arbutus. | 13. Groundsel Tree. |
| 5. Bay. | 14. Holly. |
| 6. Bignonia. | 15. Honeysuckle. |
| 7. Box. | 16. Juniper. |
| 8. Brooms. | 17. Ivy. |
| 9. Cassine, or South Sea Tea Tree. | 18. Kalmia. |
| | 19. Lavender. |

7 B

20 Laurel.

- | | |
|--------------------|-------------------|
| 20. Laurel. | 28. Rose Tree. |
| 21. Laurustinus. | 29. Rosemary. |
| 22. Magnolia. | 30. Rue. |
| 23. Phillyrea. | 31. Savin. |
| 24. Privet. | 32. Spindle Tree. |
| 25. Purslane Tree. | 33. Sweet Brier. |
| 26. Pyracantha. | 34. Tea Tree. |
| 27. Rhododendron. | 35. Widow-wail. |

XII. EVERGREEN FOREST TREES.

To be planted from the middle of February till the end of April, and from September till December.

- | | |
|-------------|----------|
| 1. Cedar. | 5. Oak. |
| 2. Cork. | 6. Pine. |
| 3. Cypress. | 7. Yew. |
| 4. Fir. | |

XIII. FRUIT TREES.

To be planted in February, March, October, and November.

- | | |
|-----------------|----------------|
| 1. Almond. | 12. Nectarine. |
| 2. Apple. | 13. Nut Tree. |
| 3. Apricot. | 14. Peach. |
| 4. Berberry. | 15. Pear. |
| 5. Cherry. | 16. Plum. |
| 6. Crab Tree. | 17. Quince. |

XIV. HARDY GREENHOUSE PLANTS.

To be planted against a south wall, in the open ground, the roots covered with tan or long litter. These will not be killed

except in very severe frosts, and then they generally shoot up afresh from their roots. By this method, many curious plants, formerly only kept in greenhouses, will now ornament the walls, where they will appear in greater vigour and beauty, and many may produce both flowers and fruit, which they will not do when confined in pots in a greenhouse.

For the particular operations in gardening, see **ESPALIER, FRUIT-TREES, GRAFTING, GREEN-HOUSE, HOTBED, INARCHING, INOCULATING, ORCHARD, PLANTING, PRUNING, TREES, &c. &c.** and the culture of the different plants under their respective generic names.

GARDINER, COLONEL JAMES, a brave and pious officer in the army, the son of Captain Patrick Gardiner, of the family of Torwood-Head, by Mrs. Mary Hodge of Gladsmuir. His father had served in the army under king William III. and queen Anne, and died in Germany, after the battle of Hochstet. His maternal uncle, colonel Hodge, was killed at the battle of Steenkirck, in 1692; and his eldest brother, Robert Gardiner, at the siege of Namur, in 1695. Our hero was born at Carriden, Jan. 10th, 1688. He was educated at Linlithgow, and made a very considerable progress in the languages; but having a kind of hereditary attachment to the military life, he served very early as a cadet; and at fourteen years of age bore an ensign's commission in a Scotch regiment in the Dutch service, wherein he continued till 1702; when he received a similar commission in a British regiment from queen Anne, which he bore in the famous battle of Ramillies. In this memorable action, being sent on a desperate service, with a party of what is called the Forlorn Hope, he very narrowly escaped with his life. While calling to his men, a musket-ball entered his mouth, and without touching his tongue or his teeth, went through his neck, and came out about an inch and a half on the left side of the vertebra. Not feeling the pain at first, he began to suspect he had swallowed the ball, till he felt with loss of blood. After this he passed two nights and all next day in the open air, in extreme cold weather, and had his wound dressed at last by an ignorant barber-surgeon; in spite of all which he recovered. In 1706, he was raised to a lieutenantancy, and soon after was made a cornet in lord Stair's regiment of Scotch greys; and in 1715, a captain-lieutenant of dragoons. When the earl of Stair went ambassador to France, he appointed him his master of horse. In 1715 he was promoted to a captaincy, and in 1717 to a majority. In 1724, he was made major of an older regiment; in 1730 he was advanced to the rank of lieutenant-colonel, and in 1743 to that of colonel of a regiment of dragoons; at the head of which he fell, fighting bravely for his country, at the battle of Preston pans, on the 21st Sept. 1745; in the fifty-eighth year of his age. In his person he

was tall, graceful, strong-built, and well-proportioned. And being endowed with a strong constitution, he in his younger years plunged so deep in every fashionable vice, that his companions styled him the happy rake. But in this vortex of vice and dissipation, he was suddenly arrested in a manner almost, if not entirely, miraculous. Our limits permit us not to quote the full account of this phenomenon given by Dr. Doddridge, in his work entitled Remarkable Passages in the Life of Colonel Gardiner; but the substance of it is as follows: In July, 1719, major Gardiner, having spent the Sabbath-evening with some gay company till eleven, and having an assignation with a married woman at twelve, in order "to kill the tedious hour," took up a book, left by his mother or aunt in his chamber, entitled The Christian Soldier; wherein he expected to find some amusement from the author's spiritualizing the terms of his profession. But while reading it carelessly, he was surprised by a sudden and extraordinary blaze of light; and upon looking up, beheld to his astonishment a visible representation of our Saviour on the cross, suspended in the air, and surrounded with glory; while at the same time he thought he heard a voice, saying, "Oh sinner, did I suffer this for thee, and are these thy returns?" Struck with this amazing phenomenon, he sunk down in his arm-chair, and continued for some time insensible; from which circumstance Dr. Doddridge often suggested to him, that he was perhaps all the time asleep, and dreaming; but he himself considered it not as a dream, but a real waking vision. "Be that as it may, it was without question a message of God unto him, and the consequences were as salutary as if an angel had been sent express from heaven to convert him; and from that time to his death he became as eminently distinguished for piety as he had formerly been for profanity. In July, 1726, he married lady Francis Erskine, daughter of the earl of Buchan, by whom he had thirteen children. From the numerous anecdotes recorded of this great and good man by Dr. Doddridge, we shall only add one more, which may afford an useful example to others in an age wherein duelling is so frequent. He had been so much addicted to this

fashionable folly in his younger years, that he had fought three duels, before he was quite a man; but being challenged to fight a fourth after his conversion, he made this calm reply:—"I fear sinning, though you know I do not fear fighting." Dr. Doddridge has summed up his character in few words, in the quotation from Virgil prefixed as a motto to his work:

"——— Justior alter

Nec pietate fuit, nec bello major & armis."

GARDINER, STEPHEN, bishop of Winchester, and chancellor of England was born at Bury St. Edmunds, in 1483. He was natural son to Richard Woodville, the brother of queen Elizabeth, wife to Edward IV, and was educated at Cambridge. He signed the divorce of Henry VIII. from Katharine of Spain; abjured the pope's supremacy; and wrote "*De vera et falsa Obedientia*," in behalf of the king: yet in Edward VI's reign he opposed the reformation, and was imprisoned; but was liberated by queen Mary. He drew up the articles of marriage between her and Philip II. of Spain. He was violent against the reformers, but on his death-bed often repeated these words, *Erravi cum Petro, sed non flevi cum Petro*; "I have sinned with Peter, but I have not repented like Peter." He died in 1555.

GARET, a town of Barbary, in Fez.

GARFETE, a town of Portugal, in Alentejo.

GARGANO, a town of Naples, seven miles N. of Mount St. Angelo.

GARGANVILLARD, a town of France, in the department of Landes, seven miles N. W. of Riviere Verdun.

GARGARISM, [*γαργαρισμός*], a liquid form of medicine to wash the mouth with.

GARGARISMS, are used when the mouth and throat are inflamed, or ulcerated. A small quantity may be taken into the mouth, and moved briskly about, and then spat out; or if the patient cannot do this, the liquor may be injected by a syringe. When gargles are required, their use should be more frequently repeated than is done in common practice. See **MEDICINE**.

GARGET, a distemper in cattle. It consists in a swelling of the throat and the neighbouring parts; to prevent which bleeding in the spring is recommended.

GARGIL, a distemper in geese, which by stopping the head frequently proves mortal. Three or four cloves of garlic, beaten in a mortar with sweet butter, made into little balls, and given fasting, are the ordinary means of cure.

GARGILESSE, a town of France, in the department of Indre, five miles S. E. of Argenton.

GARGLE, a liquid with which the throat is washed. See **GARGARISM**.

GARGLION, an exsudation of nervous juice from a bruise, or the like, which indurates into a hard immovable tumour.

GARIDELLA, in botany, fennel-flower of Crete, a genus of the trigynia order, and dodecandria class of plants; natural order, Multisiliquæ. Calyx pentaphyllous, with leaves resembling flower-petals; nectaria bifid, five, bilabiate; capsules polyspermous, adhering together; seeds numerous. It has but one species.

GARLAND, in naval affairs, a sort of net extended by a wooden hoop, of sufficient size to admit a bowl or platter, and is used by sailors as a locker or cupboard, to contain their provisions.

GARLAND, [derived by Hicks from *gardel handa*, which in the northern languages signify a nosegay artfully wrought with the hand,] ornaments of flowers, fruits, and leaves, intermixed; anciently much used at the gates of temples, where feasts and solemn rejoicings were held; or at any other place where marks of public joy or gaiety were required, as at triumphal arches, tournaments, &c.

GARLAND, is also used for a chaplet made of feathers, or sometimes of precious stones, worn on the head in the manner of a crown.

GARLIC, in botany. See **ALLIUM**.

GARNET, [*granatus*], in natural history, a very beautiful gem of a red colour, with an admixture of blueish. When pure and free from blemishes, it is little inferior, in appearance, to the oriental ruby, though only of a middle degree of hardness between the sapphire and common crystal. It is found of various sizes, from that of a pin's head to an inch in diameter. Among our lapidaries and jewellers, genuine garnets are known by different names, according to their different degrees of colour. 1. The

garnet, simply so called, is the finest and most valuable kind, being of a very deep blood-red, with a faint admixture of blue. 2. The rock-ruby, a name very improperly given to the garnet, when it is of a very strong but not deep red, and has a fairer cast of the blue; this is a very beautiful gem. 3. The sorane or serain garnet, that of a yet brighter red, approaching to the colour of native cinnabar, with a faint blue tinge. 4. The almandine, a garnet only a little paler than that called the rock-ruby. Garnets are distinguished into the oriental and occidental kinds, as being found in Europe as well as the East Indies. The oriental ones are principally brought from Calicut, Cananor, and Cambay; and the European are common in Italy, Hungary, and Bohemia. It is found in great plenty in many mountains, and is usually crystallized. The primitive form of its crystals is a dodecahedron, whose sides are rhombs with angles of 78° 31' and 120° 28'. The inclination of the rhombs to each other is 120°. This dodecahedron may be considered as a four-sided prism, terminated by four-sided pyramids. It is divisible into four parallelepipeds, whose sides are rhombs; and each of these may be divided into four tetrahedrons, whose sides are isosceles triangles, equal and similar to either of the halves into which the rhomboidal faces of the dodecahedron are divided by their shorter diagonal. The integrant molecules of garnet are similar tetrahedrons. The texture of garnet, as Bergman first shewed, is foliated. Its fracture commonly conchoidal: causes single refraction: specific gravity 3.75 to 4.188. Colour usually red, often green: brittle: often attracted by the magnet: fusible per se by the blow-pipe into a black glass.

Variety 1. Noble garnet. Specific gravity 4 to 4.188: colour deep red inclining to violet: almost always in crystals.

Variety 2. Common garnet. Found in mass and disseminated, sometimes in crystals: fracture uneven, inclining to the conchoidal: specific gravity 3.75 to 4: colour various; shades of green and brown; sometimes hyacinth-red and brown-red; rarely orange-yellow. A specimen of oriental garnet, analysed by Klaproth, contained

35.75 silica
27.25 alumina
36.00 oxide of iron
0.25 oxide of manganese.

99.25

A specimen of red garnet analysed by Vauquelin, contained

52.0 silica
20.0 alumina
17.0 oxide of iron
7.7 lime.

96.7

And a specimen of black garnet,

43 silica
16 alumina
20 lime
16 oxide of iron
4 water and volat. matter.

99.

GARNETS, **COUNTERFEIT**, are made as follows: take prepared crystal, two ounces; red lead, six ounces; manganese, sixteen grains; zaffre, three grains: mix all well, put them into a crucible, cover it well with lute, and set it in a potter's kiln for twenty-four hours. Or take crystal, two ounces; minium, five ounces and a half; manganese, fifteen grains; and zaffre, four grains. Mix and bake them as above.

GARNET, in a ship, is a tackle having a pendant coming down from the mainmast, with a block well seized to the main-stay, just over the hatch-way, to which a guy is fixed to keep it steady; and at the other end is a long tackle-block, in which the fall is reeved, that so by it any goods or casks may be hauled and hoisted into or out of the ship. When this garnet is not used, it is fastened along the stay.

GARNISH, in law-books, signifies to warn; in which sense, to garnish the heir, is mentioned in stat. 27 Eliz. c. 3.

GARNISHEE, is used for the third person or party in whose hands money is attached within the liberties of the city of London, in the sheriff's court there; and he is so called, because he has had garnishment

garnishment or warning not to pay the money, but to appear and answer to the plaintiff creditor's suit.

GARNISHMENT, is a warning given to a person for his appearance, for the better furnishing of the cause and court; as where a person is sued for detaining charters or other writings delivered him by the plaintiff, and another person, upon some certain conditions; and therefore he prays that the other person may be warned to plead with the plaintiff, whether the conditions are or are not performed, which is the praying of garnishment; and interpreted to be either a warning of that other, or a furnishing the court with parties sufficient to determine the cause.

GARONNE, a fine river in the S. of France, which rises in the Pyrenees, and taking a N. W. direction, waters Toulouse and Bourdeaux, below which it is joined by the Dordogne, and thence to its entrance into the bay of Biscay is called the Gironde.

GARONNE, UPPER, a department of France, bounded on the N. by that of Lot. It contains part of the late province of Languedoc. The Garonne runs through it. Toulouse is the capital.

GARRACHICA, a sea-port town of the isle of Teneriffe.

GARRET, or **GARRET DENNIS**, an island in the Pacific ocean, about forty-two miles in circumference, N. of New Ireland. Lon. 151. 25. E. Lat. 2. 30. S.

GARRICK, **DAVID**, a celebrated actor, was descended from a French family, who being Protestants, fled to England on the revocation of the edict of Nantes. His father, Peter Garrick, was a captain in the army, and generally resided at Litchfield; but being on a reconnoitring party at Hereford, David was born there in 1716. He received his education partly at the grammar-school at Litchfield, and partly under Dr. Johnson, with whom he visited London in 1735. He was for some time under Mr. Colson, an eminent mathematician, and afterwards went into partnership with his brother in the wine-trade. This business he soon quitted for the stage. His first attempt was at Ipswich in 1741, under the assumed name of Lyddal: and the applause he met with, induced him to make his appearance at the theatre in Goodman's-fields, in the character of Richard III. The other theatres were quickly deserted, and Goodman's-fields became the resort of people of fashion, till that theatre was shut up. Garrick then formed an engagement with Fleetwood, the patentee of Drury-lane. In the summer of 1743 he played in Dublin, to such full houses, that the heat of the weather and the crowds occasioned a fever, which was called the Garrick fever. In 1747 he became joint-patentee of Drury-lane theatre; and in 1749 he married Mademoiselle Violetti, an Italian stage-dancer. In 1763 he and Mrs. Garrick made a visit to Italy, and at Paris he saw the celebrated Mademoiselle Clairon, whose future eminence he predicted. He returned to England in 1765, and in 1766 he brought out the *Clandestine Marriage*, a comedy, written in conjunction with the elder Colman. In 1769 he celebrated a fete in honour of Shakespeare, called the Jubilee at Stratford-upon-Avon. It was afterwards made an entertainment at Drury-lane, under the same title, and had a prodigious run. In 1776 he gave up his concern in the theatre for 35,000*l*. The last character he performed was Don Felix in the *Wonder*. He died in 1779, and was buried in Westminster Abbey, where a handsome monument has been erected to his memory by private friendship. Mr. Garrick was hospitable and generous, but vain and fond of flattery. He wrote several dramatic pieces, prologues, epilogues, songs, and epigrams; in the last he excelled. (Watkins.)

GARRISON, in the art of war, a body of forces, disposed in a fortress, to defend it against the enemy, or to keep the inhabitants in subjection; or even to be subsisted during the winter-season: hence, garrison and winter-quarters are sometimes used indifferently, for the same thing; and sometimes they denote different things. In the latter case, a garrison is a place wherein forces are maintained to secure it; and where they keep regular guard, as a frontier-town, a citadel, castle, tower, &c. The garrison should always be stronger than the townsmen. Winter-quarters signify a place where a number of forces are laid up in the winter-season, without keeping the regular guard. Du Cange derives the word from the corrupt Latin *garnisio*, which the latter writers use to signify all manner of munition, arms, victuals, &c. necessary for the defence of a place, and sustaining of a siege.

GARRISON, a town of Ireland, in Fermanagh, ten miles S. E. of Ballyshannon.

GARROWS, a county of Asia in India, E. of Bengal.

GARSTANG, a populous town of Lancashire, in the post-road between Preston and Lancaster. It is seated on the Wyre, which, by the late inland navigation, communicates with the Mersey, Dee, Ribble, Ouse, Trent, Darwent, Severn, Humber, Thames, Avon, &c. which navigation, including its windings, extends above 500 miles, in the counties of Lincoln, Nottingham, York, Westmoreland, Chester, Stafford, Warwick, Leicester, Oxford, Worcester, &c. Garstang is ten miles S. of Lancaster. Lon. 2. 53. W. Lat. 55. 56. N.

GARTER, in heraldry, a moiety, or the half of a bend.

GARTER, **ORDER OF THE**, a military order of knighthood, the most noble and ancient of any lay-order in the world, instituted by Edward III. The knights companions are generally princes and peers; and the king of England is the sovereign of the order. The number of knights was originally 26; but six were added in 1786, on account of the increase of the royal family. They are a corporation, having a great and little seal, &c. Their officers are a prelate, chancellor, register, king at arms, and usher of the black rod. They have also a dean, with 12 canons, and petty-canons, vergers, and 26 pensioners or poor knights. The prelate is the head. This office has always been vested in the bishop of Winchester. Next to the prelate is the chancellor; which office is vested in the bishop of Salisbury, who keeps the seals, &c. The next is the register, who by his oath is to enter upon the registry, the scrutinies, elections, penalties, and other acts of the order with all fidelity: The dean of Windsor is always register ex officio. The fourth officer is Garter and King at arms, being two distinct offices united in one person. He is the principal officer within the college of arms, and chief of the heralds. All these officers, except the prelate, have fees and pensions. The college of the order is seated in the castle of Windsor, within the chapel of St. George, and the charter-house, erected by the founder for that purpose. The habit and ensign of the order are a garter, mantle, cape, george, and collar. The three first were assigned the knights companions by the founder; and the george and collar by Henry VIII. The garter challenges pre-eminence over all the other parts of the dress, as from it the order is denominated. It is the first part of the habit presented to foreign princes and absent knights, who, as well as all other knights elect, are therewith first adorned; and it is of so great honour and grandeur, that by the bare investiture with this noble ensign, the knights are esteemed companions of the greatest military order in the world. It is worn on the left leg between the knee and calf, and is enamelled with this motto, *HONI SOIT QUI MAL Y PENSE*. The mantle is the chief of these vestments made use of upon all solemn occasions. The colour of the mantle is by the statutes appointed to be blue. The length of its train only distinguishes the sovereign from the knights companions. To the collar of the mantle is fixed a pair of long strings, anciently woven with blue silk only, but now twisted round, and made of Venice gold and silk, of the colour of the robe; with knobs or buttons and tassels at the end. The left shoulder has from the institution been adorned with a large garter, with the device, *HONI SOIT*, &c. Within this is the cross of the order, which was ordained to be worn at all times by king Charles I. At length the star was introduced, being a sort of cross irradiated with beams of silver. The collar is appointed to be composed of pieces of gold in fashion of garters, the ground enamelled blue, and the motto gold. In 1551, Edward VI. made some alterations in the ritual of this order: that prince composed it in Latin, the original whereof is still extant in his own hand-writing. He there ordained, that the order should no longer be called the order of St. George, but the order of the garter; and, instead of the George, hung at the collar, he substituted a cavalier, bearing a book on the point of his sword, with the word, *protectio* graven on the sword, and *verbum Dei* on the book: with a buckle in the left hand, and the word *fides* thereon. When the knights do not wear their robes, they are to have a silver star on the left side; and they commonly bear the picture of St. George, enamelled on gold, and beset with diamonds, at the end of a blue ribbon, crossing the body from the left shoulder. They are not to appear abroad without the garter, on penalty of 6*s*. 8*d*. paid to the register. The manner of electing a knight companion into this most noble order, and the ceremonies of investiture, are these: When the sovereign designs to elect a companion of the garter, the chancellor of the order draws up the letters, which, passing both under the sovereign's sign manual and signet of the order, are sent to the person by Garter principal king

at arms. The garter, which is of blue velvet bordered with fine gold wire, having the letters of the motto, is, at the time of election, buckled upon the left leg, by two of the senior companions, who receive it from the sovereign, to whom it was previously presented upon a velvet cushion, by Garter king at arms, with the usual reverence, whilst the chancellor reads the following admonition, enjoined by the statutes: "To the honour of God omnipotent, and in memorial of the blessed martyr St. George, tie about thy leg, for thy renown, this noble garter; wear it as the symbol of the most illustrious order, never to be forgotten or laid aside; that thereby thou mayest be admonished to be courageous; and having undertaken a just war, in which thou shalt be engaged, thou mayest stand firm, valiantly fight, and successively conquer." The princely garter being then buckled on, and the word of its signification pronounced, the knight elect is brought before the sovereign, who puts about his neck, kneeling, a dark blue ribbon, whereunto is appendant, wrought in gold within the garter, the image of St. George on horseback, with his sword drawn, encountering with the dragon. In the mean time, the chancellor reads the following admonition: "Wear this ribbon about thy neck, adorned with the image of the blessed martyr and soldier of Christ, St. George, by whose imitation provoked, thou mayest so overpass both prosperous and adverse adventures, that having stoutly vanquished thy enemies both of body and soul, thou mayest not only receive the praise of this transient combat, but be crowned with the palm of eternal victory." Then the knight elected kisses the sovereign's hand; thanks his majesty for the great honour done him; rises up, and salutes all the companions severally, who return their congratulations. Since the institution of this order, there have been 8 emperors and 28 kings, besides numerous sovereign princes, enrolled as companions. The origin of the order is variously related by historians. The common and not improbable account is, that the countess of Salisbury happening at a ball to drop her garter, the king took it up and presented it to her in these words, "Honi soit qui mal y pense; i. e. Evil to him that evil thinks. This accident gave rise to the order and the motto; it being the spirit of the times to mix love and war together. In the original statutes, however, there is not the least hint of allusion to such a circumstance, farther than is conveyed in the motto. Camden, Fern, &c. take the order to have been instituted on occasion of the victory obtained by Edward over the French, at the battle of Cressy. That prince, say some historians, ordered his garter to be displayed, as a signal of battle; in commemoration whereof, he made a garter the principal ornament of the order erected in memory of this signal victory, and a symbol of the indissoluble union of the knights. And they account for the motto, that K. Edward having laid claim to the kingdom of France, denounced shame and defiance upon him that should dare to think amiss of the just enterprise he had undertaken for recovering his lawful right to that crown; and that the bravery of those knights whom he had elected into this order was such as would enable him to maintain the quarrel against those that thought ill of it. This interpretation, however, appears to be rather forced. A still more ancient origin of this order is given in Rastell's Chronicle, lib. vi. quoted by Granger, in the supplement to his Biographical History: viz. that it was devised by Richard I. at the siege of Acres, when he caused 26 knights, who firmly stood by him, to wear thongs of blue leather about their legs; and that it was revived and perfected in the 19th year of Edward III.

GARTH is used in some parts of England for a little back-yard or close. It is an ancient British word. *Gardd*, in that language, signifies garden, and is pronounced *garth*. It is also used for a dam or wear, &c.

GARTH-MAN, in the old English statutes, one who catches fish by means of fish-garths, or wears.

GARTZ, a town of Germany, in Prussian Pomerania. Lon. 14. 18. E. Lat. 53. 13. N.

GAS is a general name for all fluids of the aerial kind, except common air. It is derived from the German *gascht* or *gast*, signifying an irruption of wind, or the ebullition attending the expulsion of elastic fluids from substances in a state of fermentation or effervescence. It was originally given by Van Helmont to the vapour of charcoal, the same with the fluid afterwards called fixed air, now carbonic acid, and also to some other factitious airs. From him the term gas has been employed by modern philosophers,

as a general one for all the elastic fluids which retain their aerial form in the common temperature of the atmosphere. Of all the modern discoveries, those relating to air, or the substances denominated gases, are the most important and interesting.

OXYGEN GAS. This gas was first obtained by the ingenious Dr. Priestley in 1774 on the first day of August. Soon after the same discovery was made by Scheele and Lavoisier. It has been called dephlogisticated air, pure air, vital air, fire-air, empyreal air, and oxygen gas which name it retains. Oxygen is combined in abundance in many metallic substances from which the gas may be obtained by the application of heat. It is most generally procured by adding good sulphuric acid to about the same bulk of the black oxide of manganese. The flame of a taper or lamp is applied, and the gas by means of a brick-tube is received in a glass inverted over water. The properties of this air has been fully examined and are now generally known. It is remarkable for its purity, and for its power of maintaining combustion and respiration. Any combustible substance, previously ignited, being introduced into this gas burns rapidly and vividly. A bit of iron-wire or watch-spring with a small bit of phosphorus and lint lighted at the end, burns brilliantly, emitting sparks. It is insipid, inodorous, highly elastic, and heavier than common air, being to it as 103 to 100. By the application of heat it is expanded; by the abstraction of heat it is contracted, in the same manner as atmospheric air, but in a different ratio. In the first 45° above the freezing point it expands less than atmospheric air; in higher temperatures it expands much more. This gas has been found of use medicinally in cases of debility, serofula, rickets, palsy, nervous affections, &c. It forms about 27 parts in 100 of atmospheric air, constituting that part which supports animal life. It also gives to acids their acid properties, and hence has been called the acidifying principle.

GAS, AZOTIC, or NITROGEN, it is also called mephitic, and is a substance unlike the former, being incapable of supporting animal life. It extinguishes flame, and is only characterised by possessing none of the distinguishing qualities of the other known airs. It is lighter than common air, in the proportion of 985 to 1000. It may be considered indeed as the residue of common air, when vitiated by combustion. It is easily disengaged from animal matters, by a slight increase of temperature; but different parts of animals afford different proportions of it, and the concrescible fibrous matter the most. The portion of it they in general afford is proportioned to their quantity of volatile alkali. Azotic or nitrogen gas, may be procured by mixing equal weights of iron filings and sulphur into a paste with water, and placing the mixture in a proper vessel over water. Then invert over it a jar full of common air, and allow it to stand exposed to the mixture a day or two. The air contained in the jar will gradually diminish, as will appear from the ascent of the water within the jar, till at last only about three-fourths of its original bulk remain. This gas is not absorbed by water: it immediately extinguishes a lighted candle, and other burning substances: it is fatal to animals confined in it: plants, however, live and flourish in it: by it delicate blue colours are slightly reddened; and when mixed with oxygen gas, in the proportion of three or four parts of azotic gas to one of oxygen, it composes a mixture resembling atmospheric air. Its basis is nitrogen, an elementary substance, which is also the basis of nitrous acid or aquafortis. Its combination with oxygen gives it the acid character. In this state it is combined with that substance. In the state of atmospheric air it is only mixed.

GAS, INFLAMMABLE, or HYDROGEN. This air, named also fire-damp, is peculiarly distinguished by its great levity and inflammability. It is the lightest substance whose weight we are able to estimate. When pure, it is thirteen times lighter than atmospheric air, and it immediately explodes on mixture with oxygen and ignition. It is formed by the union of hydrogen and caloric. Its lightness is particularly evinced by its use in balloons. Plants grow in this fluid without impairing its inflammability. Water imbibes about one-thirteenth part of it; and when again expelled, it is as inflammable as ever. Hydrogen gas is thus procured: let sulphuric acid, diluted with five or six times its weight of water, be poured on iron filings or zinc in a glass-bottle or small retort. An effervescence will ensue, and the gas which escapes is inflammable air or hydrogen gas. This effect is procured by the decomposition of the watery parts of the acid; the oxygen is absorbed

by the metal, and with the sulphur forms a solid saline mass (mar-tial vitriol or copperas). The hydrogen which enters into the composition of the water is disengaged in the form of hydrogen gas. According to M. Lavoisier, water is composed of eighty-five parts of oxygen and fifteen parts of hydrogen. This philosopher has instructed us in the following method of obtaining this gas by heat only. Let water pass drop by drop through the barrel of a gun, while it remains red-hot amidst burning coals; let a crooked tube be placed at the end of this iron, and bent, so that it may be passed into a glass-vessel full of water inverted in the pneumatic apparatus. There will then pass into the glass-vessel an aeriform fluid, which is inflammable air or hydrogen gas. In this process the water suffers a decomposition, and while the hydrogen passes into the glass-receiver, the oxygen unites with the substance of the gun-barrel, and oxidates or rusts its internal surface. Metals are very easily revived or reduced from a calx or oxide to the metallic state when heated in a receiver filled with this air. This also arises from its attraction for oxygen, which in this case is expelled from the calx; and, uniting with the hydrogen in the receiver to form water, leaves the metal pure, and in its natural state. In a strong phial mix equal parts of hydrogen gas and common air, and apply to the mouth a lighted candle, and it will produce a sudden and loud explosion. One part of oxygen gas, and two or three, of hydrogen gas, will give a report equal to that of a pistol. Hydrogen gas has an unpleasant smell; it extinguishes burning bodies; and is fatal to animals. From these three simple, or original gases, variously modified, all the rest are produced.

GAS, CARBONIC ACID. This is the first of the elastic fluids that appears to have been distinguished from common air. Dr. Black investigated its nature. From its existing in the inelastic state, in water, Dr. Black called it fixed air. Bewley termed it mephitic air; it has also been termed cretaceous and calcareous acid, but has retained the name carbonic acid, since it appears to have been ascertained, that its radical is carbon. Of this, or rather of charcoal, according to the experiments of Lavoisier, it contains twenty-eight parts by weight, to seventy-two of oxygen. Guyton Morveau considers it as composed of 17.88 pure carbon, and 82.12 of oxygen. Carbonic acid gas exceeds every other in specific gravity, except the sulphurous. Hence the vapour in the Grotto del Cano, rises but a little above the surface; and the choak-damp of miners, which is this gas, lies on the ground. Thus, too, when it is emitted from a fermenting liquor, it first fills the empty portion of the vat, displacing the lighter atmospheric air; and then flows over the sides, almost as water would do. For the same reason, if a bottle filled with it be inverted over the flame of a candle at some distance, it will descend, and extinguish it. According to the experiments of Mr Cavendish, one part of this, mixed with nine of atmospheric air, renders it incapable of supporting combustion.

GAS, CARBONIC OXIDE. This is a mixture of carbonic acid gas, and carbonic oxide; it was first made known by Mr. Cruikshank. This gas freed from carbonic acid by washing with lime-water is somewhat lighter than common air in which it does not explode when fired, but does in oxygen gas. Pure alkalis do not absorb it, but water takes up about a fifth part of its bulk. It is noxious to animals. The purest oxide of carbon is obtained, by passing the carbonic acid gas through red hot charcoal.

GAS, ATMOSPHERIC, or, COMMON AIR. This is a mixture of oxygen and azotic air, with carbonic acid, and this mixture is in the proportion of 27 parts of oxygen air, 72 of azotic, and 1 of carbonic acid gas. The proofs of this composition of atmospheric air were first offered by Mr. Scheele, who found, on its exposure to certain substances, that it suffered a diminution of volume; and that by this diminution it was rendered unfit for the support of life. This abstracted part, therefore, could not fail to be oxygen or vital air; and from this mixture of oxygen and azote, he naturally inferred that atmospheric air came to be formed. This he further confirmed by restoring oxygen to it, in consequence of which it regained all its properties of atmospheric air. On the same subject he was succeeded by Lavoisier, who, in addition to these facts, shewed that the oxygen, or attracted part, was received by the substance producing the change, and could be often recovered again from it. But though the composition of atmospheric air has been thus ascertained, something still remains want-

ing to complete it; and this is the manner of combining by experiment its parts. Hence it is doubted whether its parts exist naturally in a state of chemical combination, or of mechanical mixture; however the latter appears most probable. From this knowledge of the composition of atmospheric air, an attempt has been made to ascertain its purity, or its relative capability of supporting animal life in different situations. This is effected by eudiometry, or measuring the exact quantity of oxygen the air contains. See EUDIOMETER.

GAS, ALKALINE, or AMMONIACAL. This air possesses a strong pungent smell, and is even capable of inflaming the skin of animals. Its lightness is next to that of inflammable air, and its specific gravity is to that of atmospheric air, in the proportion of 600 to 1000. It is capable of supporting animal life, or combustion, though the flame of a candle enlarges before it is extinguished by it. It is a compound of azote and hydrogen, 1000 parts of it containing 807 of azote, and 193 of hydrogen. This air has a strong attraction for water, and is rapidly absorbed by it. When dissolved with water it produces heat; and when dissolved with ice it produces cold. Dr. Priestley first noticed this gas; it is not found in a natural state. To obtain it, put into a retort a certain quantity of liquid ammonia, and heat the bottom of the retort, and having suffered some air to escape from the retort and the tube, the gas may be collected in vessels filled with mercury. This gas, which seems to be nothing but ammonia deprived of water, is perfectly absorbable by water, and the solution forms liquid ammonia (the same which is vulgarly called sal volatile and spirit of hartshorn). It is the lightest of all the saline gases, has a penetrating odour, and gives a strong tint of green to blue vegetable colours. It combines rapidly with carbonic, muriatic, and sulphureous acid gases, and forms neutral salts, throwing out a great deal of heat, which arises from the free state of the calorific that had been combined with these gases. Ammoniacal gas suffocates animals, and extinguishes burning bodies; but it is so far inflammable, that it increases the flame of a taper before it extinguishes it.

GAS, CARBURETTED HYDROGEN. There are several varieties of this gas, the hydrogen holding different proportions of carbon in solution, according to the process by which it is obtained. The gas of stagnant water, which may be procured by stirring the mud at the bottom with a stick, and collecting the gas, as it rises in bubbles, in an inverted bottle, is this compound, as is also the fire-damp of coal-mines. The vapour of water passed through a tube containing ignited charcoal, consists of this gas and carbonic acid, which may be separated by agitating the mixture with lime diffused in water. The vapour of ether, or of alcohol, passed through a red-hot tube of porcelain, coated with clay, affords the same products. If three parts of concentrated sulphuric acid, and one of alcohol, be distilled in a glass-retort with a gentle heat, a carburetted hydrogen comes over. This is distinguished by the name of olefant gas, because when it comes in contact with oxygenated muriatic acid gas, it forms an oil. Several varieties of this gas were examined by Mr. Henry, in order to ascertain their power of affording light. The following results were determined:

GASES.	Oxygen gas required to saturate, 100 measures.		Measures of carbonic acid produced.	
Pure hydrogen.....	50	to 54		0
Gas from moist charcoal.....	60			35
oak	54			33
dried peat.....	68			43
coal.....	170			100
lamp-oil.....	190			124
stagnant water.....	200			100
wax.....	220			137
Pure olefant gas.....	284			179

The light evolved appeared to be in proportion to the oxygen consumed, so that the first four in the list yielded very little; but the last much exceeded all the rest. Of these varieties the olefant

ant gas is the heaviest, and with oxygen detonates more violently than any of the rest.

GAS, SULPHURATED HYDROGEN. This has the properties of an acid; for when absorbed by water, its solution reddens vegetable blues. It combines also with alkalis, earths, and with several metallic oxides. It has an extremely offensive odour, resembling that of putrid eggs. It kills animals, and extinguishes burning bodies. When mixed with oxygen gas, or atmospheric air, it is inflammable. To obtain it, take dry sulphuret of potass, put it into a tubulated retort in a sand-bath; or, supported over a lamp, direct the neck of the retort under the receiver placed in a pneumatic trough; then pour gradually upon the sulphuret diluted sulphuric acid; a violent effervescence will take place, and sulphurated hydrogen gas will be disengaged. When no more gas is produced, apply heat by degrees till it boils, and gas will again be procured abundantly. The water employed for receiving it should be heated to about 80 or 90 degrees: at this temperature it dissolves little of the gas; but if cold water be used, a vast quantity of it is absorbed. Water impregnated with sulphurated hydrogen gas, slightly reddens blue vegetable colours. It is this gas which gives to the mineral-waters of Harrowgate and Aix-la-Chapelle their peculiar smell. Such waters may therefore be artificially imitated, by impregnating common water with this gas, and adding the other constituent parts to it. This gas acts strongly on most metallic oxides. Dip a slip of paper into a solution of lead, and expose it to the action of sulphurated hydrogen gas; and the paper will instantly become blackened. Writing performed with this solution is invisible when dry, but becomes visible when immersed in a bottle filled with this gas.

GAS, PHOSPHORATED HYDROGEN, consists of phosphorus dissolved in hydrogen gas. It is the most combustible substance in nature. It is distinguished from all other gases by the property of taking fire immediately when brought in contact with atmospheric air. When mixed with oxygen gas, or with oxygenated muriatic acid gas, it burns with great violence. When bubbles of it are suffered to pass through water, they take fire in succession as they reach the surface of the fluid. It has an insupportable odour, similar to that of putrid fish. To obtain it, take a small retort, put into it one part of phosphorus and ten of concentrated solution of potass; make the mixture boil, and receive the gas over mercury, or, if it be intended for immediate use, it may be collected over water. In this process a decomposition of the water takes place. Its oxygen unites to part of the phosphorus, forming phosphoric acid, which joins to the potass, and forms phosphate of potass. The hydrogen of the water dissolves another part of the phosphorus, and is converted into phosphorated hydrogen gas. In preparing this gas the body of the retort should be filled as nearly as possible with the mixture, otherwise the first portion of gas which is produced inflames in the retort, a vacuum is formed, and the water is forced up into the retort, which endangers the bursting of it. Phosphorated hydrogen gas is also formed by nature. The air which burns at the surface of certain springs, and forms what is called burning springs, and the ignis fatuus (jack o'lantern), which glides along burying-grounds consist of this gas. If the bubbles of air which come from the retort are suffered to escape into the atmosphere, they will burst with a slight explosion, and produce flashes of fire. A circular dense white smoke rises like a ring, enlarging itself continually in an extremely beautiful manner, if the air be perfectly tranquil. This gas burns with a green light, in nascent oxygenated muriatic acid gas, under the surface of water. Put into a deep glass some phosphoret of lime, broken into pieces of the size of a pea, and add half as much oxygenated muriate of potass. Fill the vessel with water, and bring into contact with the materials at the bottom of the fluid some concentrated sulphuric acid. This may be most conveniently done, by letting the acid fall through a long funnel reaching to the bottom of the vessel. As soon as the decomposition of the water, and that of the oxygenated muriate takes place, flashes of fire dart from the fluid, and illuminate the bottom of the vessel with a beautiful green light. A ribbon, impregnated with solution of gold, may be gilt, by the action of phosphorated hydrogen gas.

GAS, NITROUS. This name is given to an aeriform fluid, consisting of a certain quantity of nitrogen gas and oxygen: first described by Priestley, but in some measure known before to Hales.

It is colourless, having no sensible taste, and is neither acid nor alkaline: it cannot be respired. The greater number of combustible bodies cannot burn in it. It is nevertheless capable of supporting the combustion of some bodies. Phosphorus burns in it, when introduced in a state of inflammation; pyrophorus takes fire in it spontaneously. To obtain it, put into a small retort some pieces of copper, and pour on them nitric acid diluted with water; an effervescence takes place, and nitrous gas will be produced. After having suffered the gas to escape for a few minutes, on account of the common air contained in the retort, collect the gas in the water apparatus as usual. In order to obtain this gas in a pure state, it should be shaken for some time in contact with water. In this process the acid undergoes a partial decomposition; the metal robs the nitric acid of the greatest part of its oxygen, and becomes oxydated. This gas has the property of absorbing the oxygen of the atmosphere; on this property Priestley formed his eudiometers. See EUDIOMETER.

GAS, NITROUS OXIDE. This is sometimes called the gaseous oxide of nitrogen, a compound of nitrogen with a still less proportion of oxygen than the preceding gas. It is a permanent gas. A candle burns in it with a brilliant flame and crackling noise: before its extinction the white inner flame becomes surrounded with a blue one. Phosphorus introduced to it in a state of inflammation burns with increased splendour, as in oxygen gas. Sulphur introduced into it when burning with a feeble blue flame, is extinguished; but when in a state of vivid inflammation it burns with a rose-coloured flame. Lighted charcoal burns in it more brilliantly than in atmospheric air. Iron wire with a small piece of wood affixed to it, and introduced inflamed into a vessel filled with this gas, burns rapidly, and throws out bright scintillating sparks. Nitrous oxide is rapidly absorbed by water which has been boiled; a quantity of gas equal to rather more than half the bulk of the water may be thus made to disappear: the water acquires a sweetish taste, but its other properties do not differ perceptibly from common water. The whole gas may be expelled again by heat. It does not change blue vegetable colours. It has a sweet taste, and a faint but agreeable odour. This gas is produced when substances, having a strong affinity with oxygen, are added to nitric acid, or to nitrous gas. It may therefore be obtained by various methods, in which nitrous gas or nitric acid is decomposed by substances capable of attracting the greater part of their oxygen. The most commodious and expeditious, as well as the cheapest mode of obtaining it, is by decomposing nitrate of ammonia by heat in the following manner: Put into a glass-retort some pure nitrate of ammonia, and apply to it an Argand's lamp; the salt will soon liquefy, and when it begins to boil gas will be evolved. Increase the heat gradually, till the body and neck of the retort become filled with a milky white vapour. In this state the temperature of the fused nitrate is between 340 and 480 degrees. After the decomposition has proceeded for some minutes, so that the gas, when examined, quickly enlarges the flame of a taper, it may be collected over water. Care should be taken during the whole process never to suffer the temperature of the fused nitrate to rise above 500 degrees Fahrenheit, which may be easily judged of from the density of the vapours in the retort, and from the quick ebullition of the fused nitrate; for if the heat is increased beyond this point, the vapours in the retort acquire a reddish and more transparent appearance, and the fused nitrate begins to rise; at 700° or 800° it explodes. After it is obtained it should stand over water several hours to render it fit for respiration, or other experiments. To experience its effects in breathing it, put about a gallon into a large bladder, or oiled silk-bag, having a tube attached to it of three-fourths of an inch in diameter. First, the common air must be expelled from the lungs, before the tube is received into the mouth, and the nostrils must be accurately closed with the hand. It must then be breathed backwards and forwards into the bag for a minute or two; some have gone as far as four or five minutes. It generally produces a pleasant thrilling, particularly in the chest and extremities, frequently with an inclination to laugh, and sometimes an irresistible propensity to gesticulation and muscular exertion. The mind meanwhile is often totally abstracted from all surrounding objects. Sometimes its effects are not entirely dissipated for some hours; and it is remarkable, that, however strong they may have been, no sense of debility or languor is induced after they have subsided. On a few individuals, however,

however, its effects have been unpleasant and depressing; in some it has produced convulsions, and other nervous symptoms; and on some it has had no sensible effect.

GAS, FLUORIC ACID. The radical of fluoric acid gas is unknown. It may be obtained by decomposing fluat of lime (Derbyshire spar), by means of sulphuric acid. For this purpose, put one part of powdered fluat of lime into a leaden retort, and pour over it two or three parts of sulphuric acid. A violent action ensues, and fluoric acid gas is extricated, which must be collected over mercury, either in a leaden or tin vessel, or in a glass-receiver covered within with a coat of varnish or wax. When no more gas is produced, the action of the acid must be assisted by a gentle heat. The most remarkable property of this gas is its power of dissolving silex: it therefore dissolves glass-crystals, and various precious stones. It is heavier than common air. It does not maintain combustion, nor can animals breathe it. It is absorbed by water, and forms with it liquid fluoric acid. It has a penetrating odour. It corrodes animal and vegetable substances. Light has no effect upon it. It emits white fumes, when in contact with moist atmospheric air. It reddens blue vegetable colours. With ammonia, it forms a concrete body. It has no action upon platina, gold, silver, mercury, tin, lead, antimony, cobalt, nickel, or bismuth; but it corrodes iron, arsenic, and manganese. The property of dissolving silex has caused it to be applied to etching on glass, which is done either by means of the fluoric acid gas, or liquid fluoric acid.

GAS, MURIATIC ACID is obtained by exposing to heat fuming muriatic acid, put into a retort, the beak of which is introduced below a bell filled with mercury, and placed on the shelf of a mercurial pneumatic apparatus. You may obtain it also with the same apparatus, if, instead of muriatic acid, you expose to heat a mixture of muriate of soda, or marine salt and sulphuric acid; the sulphuric acid combines with the soda the base of the marine salt, and the muriatic acid remaining free, passes into the state of muriatic acid gas. Muriatic acid gas is perfectly soluble in water, and in a very short time. If you therefore introduce into the bell, in which the gas has been collected, a small quantity of water, the latter, by its relative lightness, will rise to the surface of the mercury; the gas will be immediately absorbed entirely, and dissolved in the water; the mercury will ascend towards the top of the bell; and the liquor found above the mercury will be real muriatic acid, more highly concentrated, according as there is more gas and less water. Muriatic acid gas, therefore, is nothing else than the muriatic acid itself deprived of water; that is to say, as much concentrated as possible, and combined with caloric, which causes it to assume the gaseous form. Muriatic acid gas has a sharp pungent odour. If a little of it be mixed with atmospheric air, it produces, like the muriatic acid, white fumes or vapours, occasioned by the combination of the gas with the moisture of the air. This gas is much heavier than atmospheric air. It gives the same signs of acidity as the muriatic acid itself; and this indeed ought to be the case, as it is the same substance. It reddens blue vegetable colours, but it destroys neither them nor any of the other colours, as the oxygenated muriatic gas does. It combines with all the alkaline bases, and forms with them muriatic salts. If it is mixed with ammoniacal gas, it combines with it, and forms muriate of ammonia. It suffocates animals immersed in it, and extinguishes a lighted taper; but it first enlarges its flame, and makes it appear of a green or bluish colour at the edges.

GAS, OXYGENATED MURIATIC ACID. The dephlogisticated muriatic acid of Scheele, under a gaseous form, is the muriatic acid gas surcharged with oxygen. This gas is obtained by exposing the muriatic acid to heat and evaporation, whilst it is acting on a substance which contains oxygen; such, for example, as the native oxide of manganese: if you therefore put black oxide of manganese and muriatic acid into a glass-retort, and expose them to heat, a strong fermentation will be excited, during which the muriatic acid will be converted into gas, but surcharged with oxygen, which is taken from the oxide of the manganese, because it has a greater affinity for that substance. It may be prepared in the water-apparatus, though it is absorbable by water. This gas destroys vegetable colours entirely. All flowers, and the green leaves of plants, are rendered white by it, and alkali is not capable of restoring their colours. This effect can only be ascribed

to the absorption of oxygen. This gas, which contains oxygen in excess, gives up a part, which vegetable substances absorb with avidity, and by this absorption lose their colour. The oxygenated muriatic acid gas then becomes converted into common muriatic acid gas. This property has given rise to a new method of bleaching, which has proved successful. See BLEACHING. Other gases of less importance will be noticed under their respective bases, and the properties of these further noticed. For the specific gravity of the gases, see SPECIFIC GRAVITY.

GASCOIN, or GASCOIGN, is the hinder thigh of a horse, which begins at the stifle, and reaches to the ply or bending of the ham.

GASCONY, a late province of France, bounded by Guienne on the N. by Languedoc on the E. by the Pyrenees on the S. and by the Bay of Biscay on the W. It had its name from the Gascons, its ancient inhabitants. It now forms along with Armagnac the department of Gers.

GASPEZIA, a tract of country, in Lower Canada, S. of the Lawrence, and N. of Coralein's Bay.

GASSENDI, one of the most celebrated philosophers France has produced, was born at Chanterrier, about three miles from Digne in Provence, in 1592. When a child, he took delight in gazing at the moon and stars in clear unclouded weather. This frequently drew him into bye-places, to feast his eyes undisturbed; by which means his parents had him often to seek, with many anxious fears. They therefore put him to school at Digne; where he soon made such extraordinary progress in learning, that some persons, who had seen specimens of his genius, resolved to have him removed to Aix, to study philosophy under Fesay, a learned minor friar. He was afterwards invited to be professor of rhetoric at Digne, before he was quite sixteen years of age; and he had been engaged in that office but three years, when Fesay dying, he was made professor in his room at Aix. There he composed his "Paradoxical Exercitations;" which, coming to the hands of Nicholas Peirese, that great patron of learning joined with Joseph Walter prior of Valette in promoting him; and he having entered into holy orders, was first made canon of the church of Digne and D. D. and then obtained the rectorship of that church. Gassendi's fondness for astronomy grew up with his years; and his reputation daily increasing, he was, in 1645, appointed royal professor of mathematics at Paris. This institution being chiefly designed for astronomy, he read lectures on that science to crowded audiences. However, he did not hold this place long; for a dangerous cough and inflammation of the lungs, obliged him, in 1647, to return to Digne for the benefit of his native air. Gassendi wrote against the metaphysics of Descartes; and divided with that great man the philosophers of his time, almost all of whom were Cartesians or Gassendians. He joined to his knowledge of philosophy and the mathematics an acquaintance with the languages and a profound erudition. He wrote, 1. Three Volumes on Epicurus's Philosophy; and six others, which contained his own Philosophy. 2. Astronomical Works. 3. The Lives of Nicholas de Peirese, Epicurus, Copernicus, Tycho Brahe, Puerbachius, and Regiomontanus. 4. Epistles, and other Treatises. All his works were collected together, and printed at Lyons, in 1658, in 6 vols. folio. He died at Paris, in 1655, aged 63.

GASSENHOVEN, a town of France, in the department of the Dyle, and late Austrian Netherlands, 3 miles N. E. of Tylemont.

GASTEIN, a town of Bavaria, in the archbishopric of Saltzburg, 36 miles S. of Saltzburg.

GASTEROSTEUS, the STICKLE-BACK, in ichthyology, a genus of fishes of the order thoracici. Body carinate on each side, somewhat lengthened, and covered with bony plates; dorsal fin single, with distinct spines between it and the head; ventral fins behind the pectoral, but above the sternum. There are thirteen species.

G. ACULEATUS, STICKLE-BACK, BANSTICLE, or SHARPLING, is common in many of the British rivers. In the fens of Lincolnshire and some rivers that proceed from them; they are found in prodigious quantities. At Spalding, once in seven or eight years amazing shoals appear in the Welland, and come up the river in form of a vast column. The quantity is so great, that they are used to manure the land, and trials have been made to obtain oil from

from them. It is said that a man being employed by the farmer to take them, has got for a considerable time 4s. a-day by selling them for a halfpenny per bushel.

GASTRIC JUICE, a thin pellucid liquor, which distils from certain glands in the stomach, for the dilution, &c. of the food.

GASTROBRANCHUS, in natural history, a genus of fishes, of the order cartilaginei. Mouth beneath, furnished with pectinal teeth in a double row on each side; body eel-shaped; carinate beneath by a soft fin, two ventral spiracles. *G. cæcus*, or the hag-fish, is about five-inches in length, in the European seas, but, in those of India attains the length of a common eel. Its appearance is very similar to that of the lamprey. It is characterized by the circumstance of exhibiting no traces of the existence of such an organ as the eye.

GASTROMANCY, or **GASTROMANTIA**, [from *gaster*, the belly, and *mantia*, divination,] a kind of divination practised among the ancients, by means of words coming or seeming to come out of the belly. There is another kind of gastromancy, which is performed by means of glasses, or other round transparent vessels, within which certain figures appear by magic art. It is thus called, because the figure appears as in the belly of the vessels.

GATAKER, THOMAS, a learned critic and divine, born at London, in 1574. He studied at St. John's college, Cambridge, and was afterwards chosen preacher at Lincoln's inn; which he quitted in 1611, for the rectory of Rotherhithe. In 1620, he made a tour through the Low Countries; and in 1624, published at London a book, entitled, "Transubstantiation declared by the Confession of the Popish Writers to have no necessary Foundation in God's Word." He wrote also a defence of this discourse. In 1642, he was appointed one of the assembly of divines, and was engaged with them in writing annotations upon the Bible. He died in July 1654, in the 80th year of his age. He published also, 1. A Dissertation upon the Style of the New Testament. 2. De Nomine Tetragrammata. 3. De Diphthongis, sive Bivocalibus. 4. An Edition and Translation of Marcus Antoninus's Meditations. 5. A Collection of Sermons, in folio; and many other works. His piety and charity were very exemplary; and his modesty was so great, that he declined all ecclesiastical dignity. His extensive learning was much admired; his house was a private seminary, and many foreigners resorted to him to receive advice in their studies.

GATE, in architecture, a large door, leading, or giving entrance, into a city, town, castle, palace, or other considerable building: or a place giving passage to persons, horses, coaches, or waggons, &c. See **ARCHITECTURE**.

GATE, or **GAIT**, in the manege, called in French *train*, is used for the going or pace of a horse.

GATES, in a military sense, are made of strong planks, with iron bars, to oppose an enemy. They are generally made in the middle of the curtain, from whence they are seen, and defended by the two flanks of the bastions. They should be covered with a good ravelin, that they may not be seen or enfiladed by the enemy. See **FORTIFICATION**.

GATES OF HELL, an expression used in Scripture figuratively to denote either the grave or the powers of darkness, *i. e.* the devil and his angels. The Mohammedans use it literally, and suppose that hell has seven gates.

GATES, a county of North Carolina, in Edenton district, bounded on the N. by Virginia, and S. by Chowan county.

GATEHOUSE, a town of Scotland, in Kirkcudbrightshire, 13 miles W. of Kirkcudbright.

GATH, or **GETI**, in ancient geography, a city of the Philistines, and one of their five satrapies. It is famous for having given birth to Goliath.

GATINOIS, or **GASTINOIS**, a late province of France, 45 miles long and 30 broad. It now forms part of the departments of the Seine and Marne, Seine and Oise, and Loiret.

GATTA, a level district of Maritime Austria, in Dalmatia, in the province of Poglizza.

GATTEN-TREE. See **CORNUS**.

GATTINARI, a town of Italy, 13 miles N. of Vercelli.

GATTON, a borough of Surrey, 19 miles from London; on the side of a hill on the road to Ryegate.

GAVALS, a town of Russia, 28 miles S. of Viborg.

GAVARDO, **GOVARDO**, or **GUARDO**, a district of the late Cisalpine republic, in the department of Mela, and late province of Bresciano.

GAVARDO, **GOVARDO**, or **GUARDO**, a town of the late Cisalpine republic, in the above district, 10 miles N. E. of Brescia.

GAUDENS, St. a town of France, in the department of Upper Garonne, and late province of Languedoc, 8 miles N. E. of Bertrand.

GAVEL, among builders. See **GABLE**.

GAVEL, in law, tribute, toll, custom, or yearly revenue; of which we had in old time several kinds. See **GABEL**.

GAVELET, in law, an ancient and special cessavit used in Kent, where the custom of gavel-kind continues, by which the tenant, if he withdraw his rent and services due to the lord, forfeits his land and tenements.

GAVELET is also a writ used in the hustings, given to lords of rent in London.

GAVELKIND, a tenure belonging to lands in the county of Kent, and formerly universal in Ireland. The word is said by Lambard to be compounded of three Saxon words, *gaf, eal, kyn*, "*omnibus cognatione proximis data*." Verstegan calls it *gavelkind*, quasi "give all kind," that is, to each child his part: and Taylor, in his history of *gavelkind*, derives it from the British *gavel*, *i. e.* a hold or tenure, and *cenned*, "*generatio aut familia*"; and so *gavel cenned* might signify *tenura generationis*. It is well known what struggles the Kentish men made to preserve their ancient liberties, and with how much success those struggles were attended. And as it is principally here that we meet with the custom of gavel-kind (though it was and is to be found in some other parts of the kingdom), we may conclude, that this was a part of those liberties; agreeable to Mr. Selden's opinion, that gavelkind, before the Norman conquest, was the general custom of the realm. The distinguishing properties of this tenure are principally these: 1. The tenant is of age sufficient to alienate his estate by feoffment, at the age of 15. 2. The estate does not escheat in case of an attainder and execution for felony; their maxim being, "the father to the bough, the son to the plough." 3. In most places he had a power of devising lands by will, before the statute for that purpose was made. 4. The lands descend, not to the eldest, youngest, or any one son only, but to all the sons together; which was indeed anciently the most usual course of descent all over England, though in particular places particular customs prevailed; and it must be allowed, that it is founded on strict justice, however contrary to the present general practice.

GAVELLO, a town of the late Cisalpine republic, in the department of Benaco, on the road to Ferrara.

GAUGAMELA, in ancient geography, a village of Aturia, lying between the rivers Lycus and Tigris; famous for Alexander's victory over Darius.

GAUGE-POINT of a solid measure, the diameter of a circle whose area is equal to the solid content of the same measure.

GAUGER, a king's officer, who is appointed to examine all tuns, pipes, hogsheads, and barrels, of wine, beer, ale, oil, honey, &c. and give them a mark of allowance, before they are sold in any place within the extent of his office.

GAUGING. See **MENSURATION**.

GAUGING-ROD, an instrument used in gauging or measuring the contents of any vessel. That usually employed is the four-foot gauging-rod. It is commonly made of box, and consists of four rules, each a foot long, and about three-eighths of an inch square, joined together by three brass joints; by which means the rod is rendered four feet long, when the four rules are quite opened, and but one foot when they are all folded together. See Plate LXXVIII, fig. 8. On the first face of this rod, marked four, are placed two diagonal-lines; one for beer and the other for wine: by means of which the contents of any common vessel in beer or wine gallons may be readily found by putting the rod in at the bung-hole of the vessel till it meets the intersection of the head of the vessel with the staves opposite to the bung-hole. For distinction of this line, there is written thereon, beer and wine gallons. On the second face, 5, are a line of inches and the gauge-line; which is a line expressing the areas of circles, whose diameters are the correspondent inches in ale gallons. At the beginning is written ale area. On the third face, 6, are three scales of lines; the

first, at the end of which is written hogshead, is for finding how many gallons there are in a hogshead, when it is not full, lying with its axis parallel to the horizon. The second line, at the end of which is written B. L. signifying a butt lying, is for the same use as that for the hogshead. The third line is to find how much liquor is wanting to fill up a butt when it is standing: at the end of it is written B. S. signifying a butt standing. In the half of the fourth face of the gauging-rod, 7, there are three scales of lines, to find the wants in a firkin, kilderkin, and barrel, lying with their areas parallel to the horizon. They are distinguished by the letters, F. K. B. signifying a firkin, kilderkin, and barrel.

GAUGING-ROD, USE OF THE DIAGONAL-LINES ON THE. To find the content of a vessel in beer or wine gallons, put the brazed end of the gauging-rod into the bung-hole of the cask, with the diagonal-lines upwards, and thrust this brazed end to the meeting of the head and staves; then with chalk make a mark at the middle of the bung-hole of the vessel, and also on the diagonal-lines of the rod, right against, over one another, when the brazed end is thrust home to the head and staves; then turn the gauging-rod to the other end of the vessel, and thrust the brazed end home to the end as before. Lastly, see if the mark made on the gauging-rod come even with the mark made on the bung-hole when the rod was thrust to the other end; which if it be, the mark made on the diagonal-lines will, on the same lines, shew the whole content of the cask in beer or wine gallons. If the mark made on the bung-hole be not right against that made on the rod when you put it the other way, then right against the mark made on the bung-hole make another on the diagonal lines; and the division on the diagonal-line between the two chalks will shew the vessel's whole contents in beer or wine gallons. Thus, *e. gr.* if the diagonal-line of a vessel be 28 inches four-tenths, its contents in beer gallons will be near 51, and in wine gallons 62. If a vessel be open, as a half-barrel, tun, or copper, and the measure from the middle on one side to the head and staves be 38 inches, the diagonal-line gives 122 beer gallons: half of which, viz. 61, is the content of the open half-tub. If you have a large vessel, as a tun or copper, and the diagonal-line taken by a long rule proves 70 inches; the content of that vessel may be found thus: every inch at the beginning-end of the diagonal-line call ten inches. Thus ten inches becomes 100 inches; and every tenth of a gallon call 100 gallons; and every whole call 1000 gallons. *Example.* At 44.8 inches on the diagonal beer-line is 200 gallons; so that four inches 48 parts; now called 44 inches eight-tenths, is just two-tenths of a gallon, now called 200 gallons; so also if the diagonal-line be 76 inches and seven-tenths, a close cask of such diagonal will hold 1000 beer gallons; but an open cask but half so much, viz. 500 beer gallons.

GAUGING-ROD, USE OF THE GAUGE-LINE ON THE. To find the content of any cylindrical vessel in ale-gallons; seek the diameter of the vessel in inches, and just against it on the gauge-line is the quantity of ale gallons contained in one inch deep: this multiplied by the length of the cylinder will give its content in ale gallons. *E. Gr.* Suppose the length of the vessel 32.06, and the diameter of its base 25 inches; to find what is the content in ale-gallons. Right against 25 inches on the gauge-line is one gallon and 745 of a gallon: which multiplied by 32.06, the length, gives 55.9447 gallons for the content of the vessel. The bung-diameter of a hogshead being 25 inches, the head-diameter 22 inches, and the length 32.06 inches; to find the quantity of ale-gallons contained in it.—Seek 25, the bung-diameter, on the line of inches; and right against it on the gauge-line you will find 1.745: take one-third of it, which is .580, and set it down twice: seek 22 inches in the head-diameter, and against it you will find on the gauge-line 1.356; one-third of which added to twice .580, gives 1.6096; which multiplied by the length 32.06, the product will be 51.603776, the content in ale gallons. Note, this operation supposes, that the aforesaid hogshead is in the figure of the middle frustum of a spheroid. The use of the lines on the two other faces of the rod is very easy; you need only put it down-right into the bung-hole (if the vessel you desire to know the quantity of ale-gallons contained therein lie lying) to the opposite staves; and then where the surface of the liquor cuts any one of the lines appropriated to that vessel, will be the number of gallons contained in that vessel.

GAUL, the English translation of Gallia, the ancient name given by the Romans to the country now called France. The

original inhabitants were descending from the Celtes or Gomerians, by whom the greatest part of Europe was peopled; the name of Galli, or Gauls, being probably given them long after their settlement in that country. See GALLIA.

GAULTHERIA, in botany, a genus of the monogynia order, and decandria class of plants: natural order, Bicornes. Exterior calyx diphyllous, interior quinquefid; corolla ovate; nectarium consists of ten subulated points; capsule quinquelocular, covered with the interior calyx formed in the shape of a berry. There are two species.

GAUNERSDORFF, a town of Austria, 16 miles N. N. E. of Vienna.

GAUNT-BELLIED, in the manege, a term applied to a horse whose belly shrinks up towards his flanks.

GAVOT, GAVOTTA, or GAVOTTE, a kind of dance, the air of which has two brisk and lively strains in common time, each of which is twice played over.

GAUR, a country of Asia, between Balk and Candahar. Also the name of the capital.

GAURA, in botany, VIRGINIAN LOOSE-STRIPE, a genus of the monogynia order, and octandria class of plants; natural order, Calycanthaceae. Calyx quadrifid, tubular; corolla pentapetalous, the petals rising upwards; nut inferior, monospermous, quadrangular. It has but one species.

GAUTS or INDIAN APPENINES, a stupendous wall of mountains, extending from Cape Comorin, the S. extremity of the peninsula of Hindostan, to the Tapy, or Surat river, at unequal distances from the coast; seldom more than 60 miles, commonly about 40, and in one part it approaches within six miles.

GAUZE, GAUSE, or GAWSE, in commerce, a very slight, thin, open kind of stuff, made of silk, and sometimes of thread; there are also figured gauzes, and some with gold or silver flowers on a silk ground.

GAY, JOHN, a celebrated English poet, descended from an ancient family in Devonshire. He was born at Exeter, and educated at the free school of Barnstaple, under Mr. Rayner. In 1712, he became secretary to the duchess of Monmouth. In 1714, he accompanied the earl of Clarendon to Hanover. On Queen Anne's death, he returned to England, where he lived in the highest estimation and friendship with many persons of the first distinction. He was particularly noticed by Queen Caroline, to whom he read in MS. his tragedy of the Captives; and in 1726 dedicated his Fables, by permission to the duke of Cumberland. From this countenance shewn to him, and numberless promises of preferment, it was supposed, that he would have been genteelly provided for in some office suitable to his inclination and abilities. But instead of this, in 1727, he was offered the place of gentleman-usher to one of the youngest princesses. Considering this as rather an indignity to a man of his talents, he thought proper to refuse it; and some pretty warm remonstrances were made on the occasion by his sincere friends and patrons the duke and duchess of Queensberry, who withdrew from court in disgust. Mr. Gay's dependencies on the delusive promises of the great, he has figuratively and humourously described in his fable of the Hare with many friends. The profits of his poems he lost in 1720 in the South-Sea scheme. But the very extraordinary encouragement he met with from the public soon made ample amends for those private disappointments. For, in 1727-8, appeared his Beggar's Opera; the vast success of which was not only unprecedented, but almost incredible. The satire of this piece was so striking; and so perfectly adapted to the taste of all ranks that it overthrew the Italian opera, that Dagon of the nobility and gentry, which they had so long idolized, and which Dennis and many other writers had in vain, by the force of reason alone, endeavoured to drive from the throne of public taste. The profits were so very great, both to the author and Mr. Rich the manager, that it gave rise to a popular pun, viz. *That it had made Rich gay, and GAY rich.* He wrote several other dramatic pieces, and many valuable ones in verse. Among the latter, his Trivia; or the Art of walking the Streets of London, though his first poetical attempt, recommended him to the esteem and friendship of Mr. Pope: but as, among his dramatic works, his Beggar's Opera will perhaps ever stand as an unrivalled masterpiece; so, among his poetical works, his Fables hold the same rank of estimation. Mr. Gay's disposition was sweet and affable, his temper generous, and his conversation agreeable. He died in Dec. 1732.

GAZA, THEODORE, a famous Greek in the 15th century, born in Thessalonica, in 1398. His country being invaded by the Turks, he retired into Italy; where he at first supported himself by transcribing ancient authors. His uncommon parts and learning soon recommended him to public notice. In 1450, he was invited to Rome by Pope Nicholas V.; and on his death, in 1456, to Naples, by king Alphonso: who dying in 1458, he returned to Rome, where cardinal Bessarion procured him a benefice in Calabria. He was one of those to whom the revival of learning in Italy was principally owing. He translated from the Greek into Latin, Aristotle's History of Animals; Theophrastus on plants; and Hippocrates's Aphorisms; and put into Greek, Scipio's Dream, and Cicero's Treatise on Old Age. He wrote a Grammar and several other works in Greek and Latin; and died at Rome in 1478, aged 80.

GAZA, in ancient geography, a principal city and one of the five satrapies of the Philistines. It was situated about 100 stadia from the Mediterranean, on an artificial mount, and strongly wall-ed round.

GAZE-HOUND, or **GAST-HOUND**, one that makes more use of his sight than of his nose. Such dogs are much used in the north of England: they are fitter in an open champaign country, than in bushy and woody places.

GAZETTE, [*gazetta*, is a Venetian halfpenny, the price of a newspaper, of which the first was published at Venice,] a paper of public intelligence. With us it is confined to that paper of news published by authority. The first English gazette was published at Oxford, the court being there, in a folio half-sheet, Nov. 7, 1665. On the removal of the court to London, the title was changed to the London Gazette. The Oxford Gazette was published on Tuesdays, the London on Saturdays: and these have continued to be the days of publication ever since.

GAZETTEER, in literature, a title for Geographical Dictionaries, giving a brief account of the various countries, kingdoms, cities, towns, republics, &c. in the world, in alphabetical order.

GAZNA, a city of Asia, once much celebrated, and the capital of a very extensive empire; but which is now either entirely ruined, or become of so little consideration, that it is hardly taken notice of by geographers. This city was anciently an emporium and fortress of Zablestan, near the confines of India.

GAZONS, in fortification, pieces of fresh earth, covered with grass, cut in the form of a wedge about a foot long and half a foot thick, to line parapets and the traverses of galleries.

GDOV, a town of Russia, in the government of Petersburg, 90 miles S. S. W. of Petersburg.

GECCO, in natural history, a name given by the Indians to their terrible poison, the smallest quantity of which kills when mixed with the blood. They say that it is a venomous froth or humour vomited out of the mouths of their most poisonous serpents; which they procure in this fatal strength, by hanging up the creatures by the tails, and whipping them to enrage them; they collect this in proper vessels as it falls; and when they would use it, they either poison a weapon with it, or wounding any part of the flesh introduce the smallest quantity imaginable into it; which is said to cause immediate death.

GEDERN, a town of Germany, 24 miles E. N. E. of Frankfurt on the Maine.

GEEONG, a town in the island of Borneo.

GEFLE, a river of Sweden, in the province of Gestricia which runs into the Gulf of Bothnia.

GEFLE, or **GEWLE**, an ancient and populous town of Sweden, in Gestricia, 60 miles N. of Upsal.

GEHENNA, or **GEHINNON**, [*gevva*, Gr. of *גיהנום*, Heb. the valley of Hinnom,] a scripture-term which has given some trouble to the critics. It occurs in St. Matthew, v. 22, 29, 30. x. 28. xviii. 9, xxiii. 15, 33. Mark, ix. 43, 45, 47, Luke, xii. 5. James, iii. 6. The authors of the Louvain and Geneva versions retain the word *gehenna* as it stands in the Greek; the like does M. Simon: the English translators render it by hell and hell-fire, and so do the translators of Mons and Father Bohours. In the valley of Hinnom, near Jerusalem, there was a place named Tophet, where the idolatrous Jews sacrificed their children to Moloch, by fire. K. Josias, to render this place for ever abominable, made a common sewer of it, where all the filth and carcasses of the city were cast; and where a continual fire was kept up, to burn those carcasses; for which reason, as the Jews had no proper term in their

language to signify hell, they made use of *gehenna* or *gehinnon*, to denote a fire unextinguishable.

GEISINGEN, town of Germany, in Suabia, in the principality of Furstenberg, 29 miles N. W. of Constance.

GEISLINGEN, an imperial town of Suabia, on the Cocher, 12 miles W. of Ulm.

GEISMAR, a town of Hesse-Cassel, 22 miles W. of Gottin-gen.

GELA, in ancient geography, a city of great extent on the S. of Sicily, so named from the Gelas. It is now called *Terra Nuova*.

GELATINE, in chemistry, a semitransparent and colourless jelly, obtained from animal substances. If a piece of the skin of an animal be well cleaned, and repeatedly soaked and washed in cold water, till the water ceases to be coloured, and the skin be then boiled for some time in pure water, some of it will be dissolved, and on evaporation will yield gelatine. It is the same with glue only that the glue is not quite free from impurities, or extraneous matter. On being exposed to dry air it obtains its hardness, and breaks with a glassy fracture. Gelatine has neither taste nor smell; it is soluble in hot acids and alkalies; but there is no action between any of the earths and this substance. Some of the metallic oxides and salts form precipitates with gelatine in its solution in water, and the compound thus formed is insoluble. Gelatine forms a copious white precipitate with tan, which is brittle and insoluble in water, and is not changed by exposure to the air. It is composed of carbon, hydrogen, azote, and oxygen, with small portions of phosphate of lime and of soda. It is a principal part both of the solid and fluid parts of animals, and is employed in the state of glue, size, and isinglass.

GELD, in the English old customs, a Saxon word signifying money, or tribute. It also denoted a compensation for some crime committed: hence *wergeld*, in their ancient laws, was used for the value of a man slain; and *orfeld*, of a beast.

GELDERS. See **GUELDERS**.

GELDING, the operation of castrating any animal, particularly horses. A colt may be gelded at nine or fifteen days old, if the testicles have come down; as the sooner he is gelded the better it will be for his growth, shape, and courage; though the operation may be performed at any age, if proper care be taken in the management. The manner of doing it is usually this: The beast being cast down on some soft place, the operator takes the testicles between his foremost and his great finger, and, slitting the scrotum, presses the stones forth; then taking a pair of nippers made very smooth, either of steel, box, or Brazil wood, he claps the chord to the testicles between them, a very little above where the stones are set on, and presses them so hard that the course of the blood through the artery is interrupted; then with a thin, drawing, cauterising iron, he sears away the testicle. This done, he takes a hard plaster, made of rosin, wax, and turpentine, well dissolved together, and melts it on the seared part, till he has laid a good thickness of it upon the cauterized edge. When this is done to one testicle, the nippers are loosened, and the like is done to the other; and the two incised edges of the scrotum are brought close together, and kept in that situation by pieces of sticking plaister. If the part inflames violently, the horse should be bled, and a poultice of rye-meal, linseed-meal, and water, should be applied. A considerable improvement, however, on this operation, would be to perform it either by applying a strong ligature round the chord of the testicle, or by taking up the blood-vessels separately; for the method commonly used is sometimes fatal to the horse, owing to the violent inflammation brought on by the actual cautery. The manner of gelding a hog is as follows:—The operator, after having made two cross-slits or incisions on the midst of the stones, presses them out, and takes off the stone. But another general method, yet somewhat more difficult, is, first, to cut on the side of one stone, and after having drawn and cut it off, the operator puts in his fingers at the same slit, and with a lancet cuts the skin between the two stones, and by that slit presses out the other stone; and thus there is but one incision made in the cord. Boar-pigs ought to be gelded about six months old; yet they are commonly gelded about three or four weeks old.

GELENHAUSEN, a small town of Germany, in Wetteravia. Lon. 8. 13. E. Lat. 50. 20. N.

GELENIUS, **SEISMUND**, a learned and excellent man, born of a good family at Prague, about 1498. Erasmus, conceiving an esteem

esteem for him at Basil, recommended him to John Frobenius as a corrector for his printing-house; which laborious charge he accepted, and had a great number of Hebrew, Greek, and Latin books to correct: he also translated many works himself from the Greek into Latin; and published a dictionary in four languages, Greek, Latin, German, and Sclavonian. Profitable and honourable employments were offered him in other places, but nothing could tempt him to quit his peaceful situation at Basil. He died in 1555. All his translations are highly esteemed.

GELHEIM, a town of Germany, lately in the principality of Nassau Weilburg, now included in the department of Mont Tonnerre, 13 miles W. of Worms.

GELLIBRAND, HENRY, a laborious astronomer of the 17th century, born at London, in 1597. He became so enamoured with mathematical studies, that on the death of his father, he entered a student at Oxford, and devoted himself solely to them. On the death of Mr. Gunter, he recommended Mr. Briggs to the trustees of Gresham college, for astronomical professorship there; to which he was elected in 1617. His friend Mr. Briggs dying in 1630, before he had finished his *Trigonometria Britannica*, it was finished by Gellibrand at his request. He wrote several other works, chiefly tending to the improvement of navigation; and died in 1636.

GELLIUS, AULUS, a celebrated grammarian, who lived in the second century under Marcus Aurelius and some succeeding emperors. He wrote a collection of observations on authors, for the use of his children; and called it *Noctes Atticæ*, because composed in the nights of a winter he spent at Athens. The chief value of it is for preserving many facts and monuments of antiquity not to be found elsewhere. Critics and grammarians have bestowed much pains on this writer.

GELNHAUSEN, a town of Germany, 12 miles E. of Hanau.

GEM, a general name applied to all precious stones, which are divided into two classes; 1. The pellucid, or such as are clear, elegant and beautiful fossils, extremely hard, and of uncommon lustre; 2. The semi-pellucid gems, which are found in small detached pieces, and are composed of crystalline matter debased by earth: they are, nevertheless, of great beauty and brightness, and somewhat transparent. The value of gems depends principally on their hardness and colour. With respect to the former, the diamond is allowed to be the firmest, and can only be polished, or cut, by its own powder: next to it, the ruby, sapphire, jacinth, emerald, amethyst, garnet, onyx, jasper, agate, porphyry, and marble, are classed in the order we have enumerated. See these articles. The same classification prevails in point of colour: the diamond is universally esteemed on account of its brilliancy; the ruby for its purple; the sapphire for its blue; the emerald for its green; the jacinth for its orange; the amethyst for its carnation; the onyx for its tawny; the jasper, agate, &c. for their vermilion, green, and variegated colours; and the garnet for its transparent red.

GEMARA, or **GHEMARA**, the second part of the Talmud. The Hebrew word גמרא, gemara, is commonly supposed to denote a supplement; but in strictness it rather signifies complement, or perfection: being formed of the Chaldee גמר, gemar or gremar, "to finish, perfect, or complete, any thing." The rabbins called the Pentateuch simply the law: the first part of the Talmud, which is only an explication of that law, or an application thereof to particular cases, with the decisions of the ancient rabbins thereon, they call the *Mischna*, i. e. "second law;" and the second part, which is a more extensive explication of the same law, and a collection of decisions of the rabbins posterior to the *Mischna*, they call *Gemara*, q. d. "perfection, completion, finishing;" because they esteem it the finishing of the law, or an explication beyond which there is nothing farther to be desired.

GEMBLOURS, or **GIBLOU**, a town of France in the department of Dyle, and late province of Austrian Brabant, seated on the Orne. It is 22 miles S. E. of Brussels.

GEMINGEN, a town of Germany in the late palatinate of the Rhine, six miles N. W. of Heilbronn.

GEMINI, in astronomy, the twins; a constellation or sign of the zodiac, the third in order, representing Castor and Pollux; and marked thus, ♊. See **ASTRONOMY**.

GEMMA, or **BUD**, in botany. See **BOTANY**. Buds, as well as bulbs, which are a species of buds, constitute that part of the herb called by Linnaeus *Hybernaculum*, or the winter-quarters of the future vegetable: a very proper appellation, as it is during that severe season that the tender rudiments are protected. Plants,

considered in analogy to animals, may be reckoned viviparous and oviparous. Seeds are vegetable eggs; buds, living fetuses, or infant plants, which renew the species as certainly as the seed. Buds are placed at the extremity of the young shoots, and along the branches, being fixed by a short footstalk upon a kind of brackets, the remainder of the leaves, in the wings or angles of which the buds in question were formed the preceding year. They are sometimes placed single; sometimes two by two, either opposite or alternate; sometimes collected in greater numbers in whorls or rings. With respect to their construction, buds are composed of several parts artificially arranged. Externally, we find a number of scales that are pretty hard, frequently armed with hairs, hollowed like a spoon, and placed over each other like tiles. These scales are fixed into the inner plates of the bark, of which they appear to be a prolongation. Their use is to defend the internal parts of the bud; which, being unfolded, will produce, some, flowers, leaves, and stipulae; others, footstalks and scales. All these parts, while they remain in the bud, are tender, delicate, folded over each other, and covered with a thick clammy juice, which is sometimes resinous and odiferous, as in the *tacahamac* tree. This juice serves not only to defend the more tender parts of the embryo-plant from cold, the assaults of insects, and other external injuries; but likewise from excessive perspiration, which, in its young and infant state, would be very destructive. It is conspicuous in the buds of horse-chestnut, poplar, and willow-trees. In general, we may distinguish three kinds of buds; viz. 1. *Florifera*, that containing the flower; 2. *Folifera*, that containing the leaves; and 3. *Foliferoflorifera*, that containing both leaves and flowers.

1. **GEMMA FLORIFERA**, termed by the French *bouton fleur*, or à fruit, contains the rudiments of one or several flowers, folded over each other, and surrounded with scales. In several trees, this kind of bud is commonly found at the extremity of certain small branches, which are shorter, rougher, and less garnished with leaves than the rest. The external scales of this species are harder than the internal; both are furnished with hairs, and in general more swelled than those of the second sort. This species too is commonly thicker, shorter, almost square, less uniform, and less pointed; being generally terminated obtusely. It is called by Pliny *oculus gemmae*; and is employed in that species of grafting called inoculation, or budding.

2. **GEMMA FLORIFERA**, termed by the French *bouton à feuilles*, or à bois, contains the rudiments of several leaves, which are variously folded over each other, and outwardly surrounded by scales, from which the small stipulae, seated at the foot of the young branches, are chiefly produced. These buds are commonly more pointed than the former sort. In the hazel-nut, however, they are perfectly round; and in horse-chestnut, very thick.

3. **GEMMA FOLIFERA ET FLORIFERA**, or **GEMMA FOLIFERO-FLORIFERA**. The third sort of bud is smaller than either of the preceding; and produces both flowers and leaves, though not always in the same manner. Sometimes the flowers and leaves are unfolded at the same time. This mode of the flower and leaf-bud is termed by Linnaeus *gemma folifera et florifera*. Sometimes the leaves proceed or emerge out of this kind of bud upon a small branch, which afterwards produces flowers. This mode of the flower and leaf-bud is termed by Linnaeus *gemma folifero-florifera*, and is the most common bud of any. Such buds as produce branches adorned only with leaves, are called barren; such as contain both leaves and flowers, fertile. From the bulk of the bud we may often with ease foretell whether it contains leaves only, or leaves and flowers together, as in cherry and pear-trees. Neither the buds produced on or near the root, called by some authors *turiones*; nor those produced on the trunk, and from the angles or wings of the leaves, contain, in strict propriety, an entire delineation of the plant; since the roots are wanting; and in various buds, shoots are contained with leaves only, and not with flowers; but as a branch may be considered as a part similar to the whole plant, and, if planted, would in process of revegetation exhibit or produce roots and flowers, we may in general allow, that the bud contains the whole plant, or the principles of the whole plant, which may be unfolded ad libitum; and thus resembles the seed in containing a delineation of the future plant in embryo: for although the bud wants a radicle, or plumula, of which the seed is possessed, yet it would undoubtedly form one, if planted in the earth. But as the medullary part adhering to the bud is too tender, and by the abundance of juice flowing into it from the earth would be disposed

disposed to putrefaction, the buds are not planted in the soil, but generally inserted within the bark of another tree; yet placed so that the production of the marrow or pith, adhering to them, may be inserted into the pith of the branch in which the fissure or cleft is made; by which means there is a large communication of juice. This propagation by gems or buds, called inoculation, is commonly practised with the first sort of buds above described. From the obvious uses of the buds, we may collect the reason why the Author of nature has granted this sort of protection to most of the trees that are natives of cold climates: and, on the other hand, denied it to such as, enjoying a warm benign atmosphere, have not the tender parts of their embryo-shoots exposed to injuries and depredations from the severities of the weather.

GEMONLÆ SCALE, or **GEMONII GRADUS**, in Roman antiquity, was much the same as gallows or gibbet in Britain. Some say they were thus denominated from the person who raised them; others, from the first criminal that suffered on them; and others, from the verb *gemo*, "I sigh, or groan."

GEMUND, or **GEMUNDEN**, a town in Franconia, 37 miles E. of Franfort.

GEMUND, or **GEMUNDE**, late a town in the duchy of Juliers, now included in the department of the Roer. It is seated on the Roer, 24 miles S. W. of Cologne.

GEMUND, or **GMUND**, in Suabia, on the Reims, 24 miles E. of Stutgard, and 30 N. by W. of Ulm.

GENAP, or **GENEPPE**, a town of France in the department of the Dyle, 15 miles S. E. of Brussels.

GENDARMES, or **GENS D'ARMES**, in the French armies, a denomination given to a select body of horse, on account of their succeeding the ancient gendarmes, who were thus called from their being completely clothed in armour.

GENDARMES, **GRAND**, were a troop composed of 250 gentlemen; the king himself was their captain, and one of the first peers their captain-lieutenant, who has under him two lieutenants, three ensigns, three guidons, and other officers.

GENDER, or **GENUS**, among grammarians, a division of nouns, or names, to distinguish the two sexes. Nouns denoting the male are called masculine, and those denoting females, feminine. This was the original intention of gender: but afterwards other words, which had no proper relation either to the one sex or the other, had genders assigned them, rather out of caprice than reason; which is at length established by custom. Hence genders vary according to the languages, or even according to the words introduced from one language into another. Thus, *arbor*, a tree, in Latin is feminine; but *arbre* in French is masculine; and *dens*, a tooth, in Latin is masculine; but *dent* in French is feminine, though the meaning is the same. The oriental languages frequently neglect the use of genders, and the Prussian has none at all. The Latins, Greeks, &c. generally content themselves to express the different genders by different terminations, as *bonus equus*, a good horse; *bona equa*, a good mare, &c. But in English we frequently go further, and express the difference of sex by different words: as boar, sow; boy, girl; buck, doe; bull, cow; dog, bitch, &c. We have also some feminines distinguished from the masculines by the variation of the termination of the male, as abbot, abbess; prince, princess; executor, executrix, &c. which is all that our language knows of any thing like genders. The Greek and Latin, besides the masculine and feminine, have the neuter, common, and the doubtful gender; and likewise the epicene, or promiscuous, which under one single gender and termination includes both the kinds. See **GRAMMAR**.

GENEALOGICA ARBOR, or **TREE OF CONSANGUINITY**, signifies a genealogy or lineage drawn out under the figure of a tree, with its root, stock, branches, &c. The genealogical degrees are usually represented in circles, ranged over, under, and aside, each other. This the Greeks called *stemma*, a word signifying crown, garland, or the like. See **CONSANGUINITY** and **DESCENT**, and the plate there referred to.

GENEALOGY, [*γενεα* and *λογος*,] history of the succession of families; enumeration of descent or order of succession.

GENEALOGY, comprehends a summary account of the relations and alliances of a person or family, both in the direct and collateral line. In divers military orders, it is required that the candidates produce their genealogy, to shew that they are noble by so many descents.

GENEP, or **GENNEP**, a strong town of Germany, in Westphalia, now included in the department of Roer. It is 5 miles S. W. of Cleves.

GENERAL, an appellation given to whatever belongs to a whole genus. See **genus**. Thus we say general-geography, diet, council, averment, issue, &c. See the articles **GEOGRAPHY**, **DIET**, &c.

GENERAL OFFICERS, in the army. See **OFFICER**.

GENERAL TERMS, among logicians, those which are made the signs of general ideas. See **LOGIC**.

GENERAL OF AN ARMY, in the art of war, he who commands in chief. See **army**. A general ought to be a man of great courage and conduct, to have great experience, and to be of good quality. His conduct appears in establishing his magazines in convenient places; in examining the country, that he may not engage his troops too far, while he is ignorant of the means of bringing them off; in subsisting them, and in knowing how to take the most advantageous posts, either for fighting or shunning a battle. His experience inspires his army with confidence, and an assurance of victory; and his quality, by creating respect, augments his authority. By his liberality he gets intelligence of the strength and designs of the enemy, and by this means is enabled to take the most successful measures. A general ought likewise to be fond of glory, to have an aversion to flattery, to render himself beloved, and to keep a strict discipline. The office of a general is to regulate the march and encampment of the army; in the day of battle to choose out the most advantageous ground; to make the disposition of the army; to post the artillery; and, where there is occasion, to send his orders by his aides-de-camp. At a siege, he is to cause the place to be invested; to order the approaches and attacks; to visit the works, and to send out detachments to secure his convoys.

GENERAL OF HORSE, and **GENERAL OF FOOT**, are posts under the general of the army, and these have upon all occasions an absolute authority over all the horse and foot in the army.

GENERAL is also used for a particular march, or beat of drum; being the first which gives notice, commonly in the morning early, for the infantry to be in readiness to march.

GENERAL is also used for the chief of an order of monks; or of all the houses and congregations established under the same rule. Thus we say, the general of the Franciscans, Cistercians, &c.

GENERALISSIMO, [*generalissimo*, Fr. from general,] the supreme commander. It is often rather a title of honour than office. Generalissimo is called also captain-general, and simply general. He commands all the military powers of a nation; gives orders to all the other general officers; and receives no orders himself but from the king. M. Balzac observes, that cardinal Richelieu first coined the word, of his own absolute authority, upon his going to command the French army in Italy.

GENERATE, in music, is used to signify the operation of that mechanical power in nature, which every sound has in producing one or more different sounds. Thus any given sound, however simple, produces along with itself, its octave, and two other sounds extremely sharp, viz. its twelfth above, that is to say, the octave of its fifth; and the other the seventh above, or, in other words, the double octave of its third major. Whether we suppose this procreation of sounds to result from an aptitude in the texture and magnitude of certain particles in the air, for conveying to our ears vibrations that bear those proportions one to another, as being determined at once by the partial and total oscillations of any musical string; or from whatever æconomy of nature we choose to trace it, the power of one sound thus to produce another, when in action, is said to generate. The same word is applied by Signior Tartini and his followers, to any two sounds which, simultaneously heard, produce a third.

GENERATED, or **GENITED**, is used, by some mathematical writers, for whatever is produced, either in arithmetic, by the multiplication, division, or extraction of roots; or in geometry, by the invention of the contents, areas, and sides; or of extreme and mean proportionals, without arithmetical addition and subtraction.

GENERATING LINE, or **FIGURE**, in geometry, is that which by its motion produces any plane or solid figure. Thus a right line moved any way parallel to itself, generates a parallelogram; round a point in the same plane, with one end fastened

ened in that point, it generates a circle. One entire revolution of a circle, in the same plane, generates the cycloid; and the revolution of a semi-circle round its diameter, generates a sphere. See GENESIS.

GENERATION, in physiology, implies the propagation of the species, whether in plants, insects, fishes, or other animals. See PHYSIOLOGY.

GENERATION, in mathematics, is used for the formation or production of any geometrical figure; as of equations, curves, solids, &c.

GENERATOR, in music, signifies the principal sound or sounds by which others are produced. Thus the lowest C for the treble of the harpsichord, besides its octave, will strike an attentive ear with its twelfth above, or G in alt, and with its seventeenth above, or E in alt. The C, therefore, is called their generator, the G and E its products or harmonics.

GENERICAL, or **GENERIC**, **NAME**, in natural history, the word used to signify all the species of natural bodies, which agree in certain essential and peculiar characters, and therefore comprehending all of the same genus, family, or kind; so that the word used as the generical name equally expresses every one of the genus, and other words expressive of the peculiar qualities or figures of each species are added, in order to denote them distinctly, and make up what is called the specific name. See BOTANY and ZOOLOGY.

GENESIS, [*γενεσις*; *genesis*, French,] **GENERATION**, the first book of Moses, which treats of the production of the world. It contains the history of the creation, and the lives of the first patriarchs. This book stands at the head of Pentateuch. Its author is held to be Moses: it contains the relation of 2369 years, viz. from the beginning of the world to the death of Joseph. The Hebrews called it *ברשית*, *Bereschith*, because it begins with that word, which in their language signifies "in the beginning." The Greeks gave it the name *Γενεσις*, *g. d.* production or generation, because it begins with the history of the production or generation of all beings. This book, besides the history of the creation, contains an account of the original innocence and fall of man; the propagation of mankind; the rise of religion; the general defection and corruption of the world; the deluge; the restoration of the world; the division and peopling of the earth; and the history of the first patriarchs to the death of Joseph. It was easy for Moses to be satisfied of the truth of what he relates in this book, because it came down to him through few hands: for from Adam to Noah there was one man, viz. Methuselah, who lived so long as to see them both: in like manner Shem conversed with Noah and Abraham; Isaac with Abraham and Joseph, from whom the facts recorded in this book might easily be conveyed to Moses by Amram, who was contemporary with Joseph.

GENESIS, in geometry, denotes the formation of a line, plane, or solid, by the motion or flux of a point, line, or surface. See FLUXIONS. The genesis or formation, *e. gr.* of a globe or sphere, is conceived by supposing a semicircle to revolve upon a right line drawn from one extreme thereof to the other, called its axis, or axis of circumvolution: the motion or revolution of that semicircle is the genesis of the sphere, &c. In the genesis of figures, &c. the line or surface that moves is called the describent; and the line round which, or, according to which, the revolution or motion is made, the dirigent.

GENESSEE, a large tract of land in New York, bounded on the N.W. and N. by lake Ontario.

GENESSEE, a river of New York, which runs into lake Ontario.

GENET, **GENNET**, or **JENNET**, in the manege. To ride *a-la-genette*, is to ride after the Spanish fashion, so short that the spurs bear upon the horse's flank.

GENETHLIA, in antiquity, a solemnity kept in memory of some person deceased.

GENETHLIACAL, [*γενεθλιακός*,] pertaining to nativities, as calculated by astronomers, to shew the configurations of the stars at any birth.

GENETHLIACI, in astrology, [from *γενεθλιον*, origin, generation, or nativity,] persons who erect horoscopes, and pretend to foretell what shall befall a man by means of the stars which presided at his nativity. The ancients called them Chaldaei, and Mathematici. Hence the several civil and canon laws, made against mathematicians, only respect the genethliaci or astrologers.

GENEVA, a late republic of Europe, on the confines of France, Savoy, and Switzerland, long in alliance with the Swiss cantons, but annexed to France in 1798. It now forms the department of Lac Lemman.

GENEVA, a city of Switzerland, on the confines of old France, and the late duchy of Savoy, now the capital of the department of Lac Lemman. It is seated on the banks of the Rhone, just at its efflux from the lake of Geneva; and part of it is built on an island in the river. It is handsome, well fortified, and pretty large; the streets in general are clean and well paved, but the principal one is encumbered with a row of shops on each side between the carriage and foot-paths. This city lies forty miles N. E. of Chamberv. Lon. 5. 55. E. Lat. 46. 11. N.

GENEVA, LAKE OF. This lake, which was anciently called Lemanus, (whence the present name of the department, Lac Lemman,) is in the shape of a crescent; Switzerland forms the concave, and the department of Mont Blanc, (Savoy,) the convex part; the greatest breadth being about twelve miles. The greatest depth of this lake, found by M. de Luc, is 160 fathoms. The Rhone runs through its whole extent from its E. to its S. W. extremity; after which it passes through the city and divides it into two unequal parts.

GENEVA, a lake of Upper Canada, which forms the W. extremity of Lake Ontario, to which it is joined by a short and narrow strait.

GENEVA, a post-town of New York, in Onondago county.

GENEVA, or **GIN**, is an ordinary malt spirit, distilled a second time, with the addition of some juniper-berries. Originally, the berries were added to the malt in the grinding; so that the spirit thus obtained was flavoured with the berries from the first, and exceeded all that could be made by any other method. At present, they leave out the berries entirely, and give their spirits a flavour by distilling them with a proper quantity of oil of turpentine; which, though it nearly resembles the flavour of juniper-berries, has none of their valuable virtues.

GENEVIEVE, ST. FATHERS, OR RELIGIOUS OF, a congregation of regular canons, established in France, in the seventeenth century. It was a reform of the Augustine canons, begun by St. Charles Faure, in the abbey of St. Vincent de Senlis, in 1618. In 1634, the abbey was made elective; and a general chapter, composed of the superiors of fifteen houses, who had received the reform, chose F. Faure coadjutor of the abbey of St. Genevieve, and general of the congregation.

GENEVOIS, or the **DUCHY OF GENEVA**, a late province of France, bounded on the N. by Switzerland. It is now included in the department of Mont Blanc.

GENGENBACH, an imperial town of Germany, in Suabia, on the Kinzig; fifteen miles S. E. of Strasburg.

GENGOUX, *Sr. late Le Royal*, a town of France, in the department of Saone and Loire, and late province of Burgundy, seventeen miles S. W. of Chalons.

GENIAL GODS, in the Pagan mythology, deities who were supposed to preside over generation. The genial gods, says Festus, were earth, air, fire, and water. The twelve signs, together with the sun and moon, were sometimes also ranked in the number.

GENIEZ, *Sr.* a town of France, in the department of Aveyron, and late province of Rouergue. It is twenty-four miles N. E. of Rhodéz.

GENII, in the Mohammedan theology, a sort of intermediate beings, supposed to exist between men and angels. They are of a grosser fabric than the latter, but much more active and powerful than the former. Some of them are good, others bad, and they are capable of future salvation or damnation like men. The Orientals suppose several ranks and degrees or different species among this kind of beings; some being peculiarly called Jin, or genii; some Peri, or fairies; some Div, or giants; and others Tacwins, or fates, of whom they relate many romantic stories.

GENIOGLOSSI, and **GENIO-HYOIDEUS**, in anatomy. See ANATOMY.

GENIOSTOMA, in botany, a genus of the monogynia order, and pentandria class of plants. Calyx turbinate, quinquefid; corolla monopetalous, tubular; anther oblong; seeds very numerous, subangulate, placed on a filiform receptacle.

GENIS, or **ST. GENIS**, a town of France, in the department of

of Mont Blanc, and the late duchy of Savoy; 12 miles W. of Chambery.

GENISTA, **BROOM**, or **DYER'S-WEED**, a genus of the decandria order, and diadelphia class of plants; natural order, Papilionaceæ. Calyx bilabiate; upper lip bidentate, under one tridentate; vexillum oblong, reflexed. There are seventeen species.

G. TINCTORIA, is a native of Britain. It rises with shrubby stalks three feet high, garnished with spear-shaped leaves placed alternate, and terminated by several spikes of yellow flowers, succeeded by pods. The branches are used by dyers for giving a yellow colour; from whence it is called dyer's-broom, greenwood, wood-waxen, or dyer's-weed. A drachm and a half of the powdered seeds operate as a mild purgative. A decoction of the plant is diuretic; and, like the former, has proved serviceable in dropsical cases. Horses, cows, goats, and sheep, eat it.

GENITES, among the Hebrews, those descended from Abraham, without any mixture of foreign blood.

GENITIVE, the second case of the declension of nouns. The relation of one thing considered as belonging in some manner to another, occasioned in the Greek and Latin, a peculiar termination of nouns called the genitive case.

GENIUS, a good or evil spirit, or dæmon, whom the ancients supposed set over each person, to direct his birth, accompany him in life, and to be his guard. See **DÆMON**. Among the Romans, Festus observes, the name genius was given to the god who had the power of doing all things, deum qui vim obtineret rerum omnium gerendarum; which Vossius, de Idol. rather chooses to read genendarum, who has the power of producing all things; by reason Censorinus frequently uses genere for gignere. The ancients had their genii of nations, of cities, of provinces, &c. The following was a very common inscription on their medals, **GENIUS POPULI ROM.** "The genius of the Roman people;" or **GENIO POP. ROM.** "to the genius of the Roman people." In this sense genius and lar were the same thing; as Censorinus and Apulius affirm they were. See **LAES**, and **PENATES**.

GENIUS, that aptitude which a man has received from nature, to perform well and easily that which others can do but indifferently, and with a great deal of pains. To know the bent of nature is the most important concern. Men come into the world with a genius determined not only to a certain art, but to certain parts of that art, in which alone they are capable of success. If they quit their sphere, they fall even below mediocrity in their profession. Art and industry add much to natural endowments, but cannot supply them where they are wanting. Every thing depends on genius. A painter often pleases without observing rules; whilst another displeases though he observes them, because he has not the happiness of being born with a genius for painting. A man born with a genius for commanding an army, and capable of becoming a great general by the help of experience, is one whose organical conformation is such, that his valour is no obstruction to his presence of mind, and his presence of mind makes no abatement of his valour. Such a disposition of mind cannot be acquired by art: it can be possessed only by a person who has brought it with him into the world. What has been said of these two arts may be equally applied to all other professions. The administration of great concerns, the art of putting people to those employments for which they are naturally formed, the study of physic, and even gaming itself, all require a genius. The Deity has thought fit to allot peculiar talents to different individuals in order to render all men necessary to one another; the wants of men being the very first link of society. He has therefore given to some particular persons, an aptitude to perform rightly some things which he has rendered difficult or impossible to others; and the latter have a greater facility granted them for other things, which facility has been refused to the former. He seems indeed to have made an unequal distribution of talents among his creatures; yet he has disinherited none; and (cases of natural lunacy excepted) a man divested of all kinds of abilities is as great a phenomenon as an universal genius. From this diversity of genius arises that difference of inclination in men, who are led to those employments for which Providence designs them, with more or less impetuosity in proportion to the greater or less number of obstacles they have to surmount, to render themselves capable of answering this vocation. Thus the inclinations of men are so very different, because they follow the same mover, that is, the impulse of their ge-

nus. This, (as with the painter,) is what renders one poet pleasing, even when he trespasses against rules; whilst others are disagreeable, notwithstanding their strict regularity. Aristotle mentions a poet who never wrote so well as when his poetic fury hurried him into a kind of frenzy. The admirable pictures in Tasso of Armida and Clorinda are alleged by some to have been drawn at the expence of a disposition he had to real madness, into which he fell before he died. "Do you imagine, (says Cicero,) that Pacuvius wrote in cold blood? No, it was impossible. He must have been inspired with a kind of fury, to be able to write such admirable verses."

GENNESARETH, in ancient geography, a lake of Lower Galilee, called also Cinnereth, 140 stadia in length, and forty in breadth; abounding in fish. St. Matthew calls it the Sea of Galilee, and St. John the Sea of Tiberias.

GENOA, the **GENOISE REPUBLIC**, or the **LIGURIAN REPUBLIC**, a late small democratic state of Italy, which extended along that part of the Mediterranean, which from it is called the Gulf of Genoa, for about 152 miles, but varied in its breadth from eight to twenty miles. It was bounded on the N. from W. to E. by Piedmont, Monterrat, the late Cisalpine republic, Placentia, Parma, a small territory belonging to Tuscany, and the late republic of Lucca. This country was a part of the ancient Liguria, whence its modern name of the Ligurian republic. It now forms a part of the kingdom of Italy, and lies between 7. 27. and 9. 25. Lon. E. and between 43. 40. and 45. 0. Lat. N.

GENOA, the capital of the late Ligurian republic, is seated on the coast of the Mediterranean sea, at the bottom of the gulph. It is 62 miles S. E. of Turin, and 63 S. of Milan. Lon. 8. 41. E. Lat. 44. 25. N.

GENTIANA, or **GENTIAN**, in botany, a genus of the digynia order, and pentandria class of plants; natural order, Rotaceæ. Corolla monopetalous; capsule superior, two-valved, one-celled, with two longitudinal receptacles. There are fifty-three species.

G. CENTAUREUM, the **LESSER CENTAURY**, of the shops, is a native of many parts of Britain. It grows on dry pastures; and its height is commonly proportioned to the goodness of the soil, as in rich soils it grows to the height of a foot, but in poor ones not above three or four inches. The plant cannot be cultivated in gardens. The tops are an useful aperient bitter, in which view they are often used in the present practice of medicine.

G. LUTEA, the **COMMON GENTIAN** of the shops. It is a native of the mountainous parts of Germany; whence the roots, the only part used in medicine, are brought to this country. These have a yellowish brown colour, and a very bitter taste. The roots of this plant are often used in medicine as stomachic bitters. In taste they are less exceptionable than most of the substances of this class. Infusions of gentian-root flavoured with orange-peel, are sufficiently grateful. Some years ago a poisonous root was discovered among the gentian brought to London; the use of which occasioned violent disorders, and in some cases death. This root is easily distinguished from the gentian, by its being internally of a white colour, and void of bitterness.

GENTILE, means a Pagan, or worshipper of false gods. The Jews called all those who were not of their race גוים *gojim*, i. e. *gentes*, which in the Greek translations of the Old Testament is rendered *ἔθνη*; in which sense it often occurs in the New Testament; as in Matth. vi. 32. "All these things do the Gentiles (or nations) seek." Whence the Latin church also used *gentes* in the same sense as our *Gentiles*, especially in the New Testament. But the word *gentes* soon got another signification, and no longer meant all who were not Jews; but those only who were neither Jews nor Christians, but followed the superstitions of the Greeks and Romans, &c. In this sense it continued among the Christian writers, till their manner of speech, together with their religion, was publicly and by authority received in the empire; when *gentiles*, from *gentes*, came into use: and then both words had two significations, viz. in treatises or laws concerning religion, they signified Pagans, neither Jews nor Christians; and in civil affairs, they were used for all such as were not Romans.

GENTILE, in the Roman law and history, sometimes expresses what the Romans otherwise called barbarians, whether they were allies of Rome or not: but this word was used in a more particular sense for all strangers not subject to the Roman empire.

GENTLEMAN, originally comprehended all above the rank

of yeomen; whereby even noblemen were truly called gentlemen. See COMMONALTY. A gentleman is usually defined among heralds, to be one, who, without any title, bears a coat of arms, or whose ancestors have been freemen: and by the coat that a gentleman giveth, he is known to be, or not to be, descended from those of his name who flourished many hundred years before. The word is formed of the French *gentil*, "fine, fashionable, or becoming;" and the Saxon *man*.

GENTLEMEN OF THE CHAPEL, officers whose duty and attendance is in the royal chapel, being in number thirty-two. Twelve of them are priests; the other twenty, commonly called clerks of the chapel, assist in the performance of divine service.

GENTOOS, in modern history, according to the common acceptance of the term, denote the professors of the religion of the bramins or brachmans, who inhabit the country called Hindoostan, or Indostan, in the East Indies, from the word *stan*, a region, and *hind* or *hindoo*: which Ferishteh, as we learn from colonel Dow's translation of his history, supposes to have been a son of Ham, the son of Noah.

GENUS, in metaphysics and logic, denotes a number of beings which agree in certain general properties common to them all; so that a genus is nothing else but an abstract idea, expressed by some general name or term. See LOGIC and METAPHYSICS.

Genus, in music, by the ancients called *genus melodia*, is a certain manner of dividing and subdividing the principles of melody, *i. e.* the consonant and dissonant intervals, into their concinnous parts. See MUSIC.

GENUS, in natural history, a subdivision of any class or order of natural beings, whether of the animal, vegetable, or mineral kingdoms, all agreeing in certain common characters. See BOTANY and ZOOLOGY.

GENUS, in rhetoric. Authors distinguish the art of rhetoric, as well as orations or discourses produced thereby, into three genera, demonstrative, deliberative, and judiciary. To the demonstrative kind belong panegyrics, genethliacons, epithalamiums, funeral-harangues, &c. To the deliberative, persuasions, dissuasions, commendations, &c. To the judiciary, accusations and defences.

GEOCENTRIC, [*γῆ* and *κέντρον*, *geocentrique*, Fr.] applied to a planet or orb considering the earth as its centre.

GEOCENTRIC LATITUDE OF A PLANET, is its distance from the ecliptic as it is seen from the earth, which even though the planet be in the same point of her orbit, is not constantly the same, but alters according to the position of the earth in respect to the planet.

GEOCENTRIC PLACE OF A PLANET, the place wherein it appears to us from the earth, supposing the eye there fixed: or it is a point in the ecliptic to which a planet seen from the earth is referred.

GEODÆSIA, [*γεωδαισία*, *geodesie*, Fr.] that part of geometry which contains the doctrine or art of measuring surfaces, and finding the contents of plain figures. See MENSURATION.

GEOFFREY OF MONMOUTH, bishop of St. Asaph, called by our ancient biographers Gallofridus Monumentensis. Leland conjectures that he was educated in a Benedictine convent at Monmouth, where he was born; and that he became a monk of that order. Bale, and after him Pits, call him archdeacon of Monmouth; and it is generally asserted, that he was made bishop of St. Asaph, in 1151 or 1152, in the reign of King Stephen. His history was probably finished after 1138. It contains a fabulous account of British kings, from Brutus the grandson of Æneas the Trojan to Cadwallader, in 690. But Geoffrey, though we may blame his credulity, was not the inventor of the legendary history. It is a translation from a MS. written in the British language, and brought to England from Armorica by his friend Gualter, archdeacon of Oxford. But the achievements of King Arthur, Merlin's prophecies, and many speeches and letters, were chiefly his own additions. In excuse for this historian, Mr. Wharton judiciously observes, that fabulous histories were then the fashion, and popular traditions a recommendation to his book.

GEOFFRÆA, or **GEOFFROYA**, in botany, a genus of the decandria order, and diadelphia class of plants; natural order, Papilionaceæ. Calyx quinquefid; fruit an oval plum; kernel compressed. There are two species. See Plate LXV.

GEOGRAPHY.

GEOGRAPHY, [from *γῆ* or *γη*, the earth, and *γραφειν*, to describe,] signifies simply a description of the earth. Geography as a science, denotes that science which describes and explains the nature and properties of the earth, as to its figure, place, magnitude, motions, celestial appearances, &c. with the various lines, real or imaginary, on its surface. Geography is distinguished from Cosmography, as a part from the whole; this latter considering the whole visible world, both heaven and earth. And from Topography and Chorography it is distinguished, as the whole from a part.

"Golnitz considers geography as either exterior or interior: but Varenius more justly divides it into general and special, or universal and particular.

"General or Universal Geography is that which considers the earth in general without any regard to particular countries; or the affections common to the whole globe, as its figure, magnitude, motion, land, sea, &c.

"Special or Particular Geography is that which contemplates the constitution of the several particular regions, or countries, their bounds, figure, climate, seasons, weather, inhabitants, arts, customs, language, &c."

From this it appears that the earth is the proper object of geography: but as it is also the object of other sciences, it is to be considered in what sense it is the object of geography. About this there is great dissension among authors; some including the consideration of its animals, others of its atmosphere, elements, &c. but because they are the province of other sciences, the object of geography is more justly restrained to the exterior parts of the earth. Hence we consider it not as an element, but chiefly as a large spherical surface, variously diversified. General geography is now to be considered; the particular geography of the various

countries, kingdoms, cities, towns, &c. being to be found in their order, under their respective names throughout this work.

HISTORY.

It is generally agreed that geography was first studied as a science by the Egyptians and Babylonians, but by which of these nations it was first cultivated is not so well determined. Herodotus tells us, that the Greeks first learned the poles, the gnomon, and the twelve divisions of the day, from the Babylonians. Pliny, and Diogenes Laertius, however, tell us, that Thales of Miletus first found out the passage of the sun from tropic to tropic; which he could not have done without the assistance of a gnomon. He is said to have been the author of two books, the one on the tropic, and the other on the equinox: both of which he probably determined by the gnomon; and thus he was led to discover the four seasons of the year, which are determined by the solstices and equinoxes. Thales also divided the year into 365 days; which was undoubtedly a method discovered by the Egyptians, and communicated by them to him. The Babylonians began to apply to this science in the time of Belus, whenever that was; or about the time they first made astronomical observations. But it may be questioned whether they brought it to any tolerable perfection till the Nabonassarean Era, 747 years before Christ. However, it may be presumed, that the Greeks were beholden to them for the astronomical rudiments of it, as well as astronomy itself, and other sciences, which the Babylonians cultivated till the destruction of their monarchy by the Persians; although it does not appear that the Greeks had any observations of the latitude or longitude from them, relating to their dominions or other parts. The Egyptians are acknowledged to have cultivated geography, and had tables or maps, as early as the time of Sesostris; but whether

MODERN AUTHORITIES.

whether they had astronomical geography, or to what degree they improved it, we know not, since the Greeks either suppressed or attributed to themselves the learning of other nations: and it is likely, that they gave over the pursuit of the sciences from the time they became subject to foreign yokes; as at present we find them involved in the grossest ignorance under the power of the Turks. Geography began to be cultivated among the Jews under Moses and Joshua, of which, the books written by those leaders, as is commonly believed, is a proof. Geography, without doubt, was cultivated by the Persians, during their several empires. They had it probably from the Babylonians: indeed, how far they improved it, or whether they made any astronomical observations, does not appear: but we find that they and the Parthians kept registers of the public roads through their dominions, for the service of the state, which looks as if they had surveyed, or at least measured them. They had also maps, as appears by that of the world, or at least of the Persian empire, which Aristagoras brought from thence, and another of Manes the founder of the Manichean sect. Of those monuments, however, none remain at present; having been destroyed in some of the revolutions that befel their empire, probably in that remarkable one made by the Arabs, who destroyed all their records, and perhaps their libraries, as they did the remains of the famous Alexandrian in Egypt. The Greeks began to lay the foundation of geography about the time of Homer, who is reckoned the first geographer among them: or rather to the time of Anaximander, 550 years before the Christian æra. They after that improved it much by applying astronomy to it, with great success, as to the theory; discovered the ways of finding the latitude and longitude of places by observations of the stars and eclipses; invented accurate methods for projecting globes and maps, which were very common among them. The first Grecian map on record is that of Anaximander, mentioned by Strabo, lib. i. p. 7. It has been conjectured, that this was a general map of the known world, and it is supposed to be the one referred to by Hipparchus under the name of the ancient map. However it was Hipparchus, the Bythinian, who first taught a regular method of making maps; he flourished about 160 years before Christ. That prince of ancient astronomers taught more expressly, that geography could not be put upon a tolerable footing, nor the situation of places determined without astronomical observations. He invented the planisphere, whereby he laid his foundation of a true projection for maps, which hath since been much improved by optics: and it is highly probable, he first introduced the terrestrial globe, inscribed with meridians, parallels, and other celestial circles, according to which places were to be ranged thereon. The honour, therefore, of reducing geography to its present form, seems to be due to Hipparchus; for though Ptolemy has been thought by some of the ancients, as well as most of the moderns, to have given the astronomical form to geography; yet that mistake has been corrected by Agathemeris, an ancient geographer near his time, who informs us, Ptolemy invented nothing of his own, but in what he did followed the opinion of the ancients. It even appears from Ptolemy himself, that Marinus Tyrius, before him, regulated his maps by meridians and parallels; and adjusted the bounds of the earth by astronomical observations. However, Ptolemy, by his collections and elucidations greatly advanced the science of geography, and seems to have fixed its ne plus ultra among them. For afterwards it appears to have been at a stand for some ages: and, during the distractions of the empire from civil wars, and foreign invasions, declined daily till the utter destruction thereof by the Turks; since when the sciences have been the least of their care. The Romans borrowed their geography from the Greeks. It does not appear that they made any observations of the latitude or longitude, or added any thing to the theory. However, in the geometrical part, they improved it greatly, by measuring or surveying the whole empire, in the time of Julius Cæsar and Augustus; and making roads throughout the same, a thing which the Greeks never thought of. They had also globes, but especially maps in great plenty, which were much improved by their itineraries. The Arabs, who, at their first setting out to conquer, after Mohammed's death, despised learning, or at least any but their own, became smitten about 823, with that of their neighbours, especially the Greeks; whose geography, (with the rest of the sciences,) they cultivated, and much improved in the

practical part, by means of observations, (chiefly of the latitude taken as well with the quadrant as gnomon,) and itineraries. They also invented new instruments, particularly the quadrant, and some think the mariner's compass, which was in use with them at least very early. But their knowledge of the earth extended very little beyond the bounds of their own empire; which at length being broken to pieces, and confined to its original limits, Arabia, they neglected the sciences by degrees, so that at present geography is little minded by them. The Turks, so long as they continued in Turkestan, their original seat, seem to have been strangers to all learning; but as soon as those of the race of Seljuk had made themselves masters of Persia, under Toghrul Beigh, about 1037, they took the sciences, which then flourished in that country, under their protection, and continued the improvement of them so long as the three dynasties of Fars, or proper Persia, Kerman, and Rum, or Anatolia, held the sovereignty. But we are as yet ignorant in what degree they advanced geography. The Moguls and Tartars having over-run the southern parts of Asia in the beginning of the thirteenth century, cherished learning wherever they found it. Kublay Kaan in China, Hulaku Khan in Persia, and afterwards Vluh Beigh in Great Bukharia, or Transoxana. Geography, in particular, received considerable improvement from their observations of the latitude of places: but civil distractions and foreign war, which ensued, left them no leisure to think of the sciences, their care for which abated as their power declined. At length being driven out of all which they possessed in the lower Asia, they returned to their ancient ignorance, wherein they, for the most part, still continue, excepting the Manchew Tartars, at present lords of China. To discover the magnitude of the earth is a problem which has probably engaged the attention of astronomers and geographers ever since the globular figure of it was known. Anaximander is said to have been the first among the Greeks who wrote upon this subject. Archytas of Tarentum, a Pythagorean, famous for his skill in mathematics and mechanics, also made some attempts in this way; and Dr. Long conjectures, that these are the authors of the most ancient opinion, that the circumference of the earth is 400,000 stadia. Aristarchus of Samos is thought to have considered the magnitude of the earth, as well as of the sun and moon. Archimedes mentions, that the ancients held the circumference of the earth to be 30,000 stadia; but it does not appear what methods were made use of by these ancient geographers to solve the problem. Perhaps they attempted it by observations of stars in the zenith or in the horizon, and actual mensuration from some part of the circumference of the earth. Aristotle, in his treatise *De Cælo*, affords a proof of this. In that work he says, that different stars pass through our zenith, according as our situation is more or less northerly; and that in the southern parts of the earth stars come above our horizon, which, if we go northward, are no longer visible. Hence it appears, that there are two ways of measuring the circumference of the earth; one by observing stars which pass through the zenith of one place, and do not pass through that of another; the other by observing some stars which come above the horizon of one place, and are observed at the same time to be in the horizon of another. Eratosthenes, made use of the former method, which is the best, at Alexandria in Egypt, B. C. 250. He knew, that at the summer-solstice the sun was vertical to the inhabitants of Syene, a town on the confines of Ethiopia, under the tropic of Cancer, where they had a well built for that purpose, on the bottom of which the rays of the sun fell perpendicularly on the day of the summer-solstice. He observed by the shadow of a wire set perpendicularly in an hemispherical bason, how much the sun was on that day at noon distant from the zenith of Alexandria; and found that distance to be the 50th part of a great circle in the heavens. Then supposing Syene and Alexandria to be under the same meridian, he concluded the distance between them to be the 50th part of a great circle upon the earth; and this distance being by measure 5000 stadia, he concluded the circumference of the earth to be 250,000 stadia; but as this number divided by 360 would give 694 $\frac{2}{3}$ stadia to a degree, either Eratosthenes himself or some of his followers assigned the round number 700 stadia to a degree; which multiplied by 360, makes the circumference of the earth 252,000 stadia; whence both these measures are given by different authors as that of Eratosthenes. In the time of Pompey the Great, Posidonius made an attempt to

measure the circumference of the earth by Aristotle's second method, viz. horizontal observations, made the measure of the earth to be 180,000 stadia, at the rate of 500 stadia to a degree. The reason of this difference is thought to be, that Eratosthenes measured the distance between Rhodes and Alexandria, and found it only 3,750 stadia. Taking this for a 48th part of the earth's circumference, which is the measure of Ptolemy's, the whole circumference will be 180,000 stadia. This measure was received by Marinus of Tyre, and is usually ascribed to Ptolemy. Ptolemy's method, however, is found to be exceedingly erroneous, on account of the great refraction in the stars near the horizon, the difficulty of measuring the distance at sea between Rhodes and Alexandria, and from his supposing these places under the same meridian, when they are really very different. Several geographers, after the time of Eratosthenes and Ptolemy, made use of the different heights of the pole in distant places under the same meridian, to find the dimensions of the earth. About A. D. 800, the khalif. Almamun had the distance measured of two places two degrees asunder, and under the same meridian; in the plains of Sinjar near the Red Sea. The result was, that the mathematicians found the degree at one time to consist of 56 miles, and at another of 56½, or 56¾. Snellius, an eminent Dutch mathematician, by taking the heights of the pole at Alcaer and at Bergen op Zoom, found the difference to be 1° 11' 30". He next measured the distance betwixt the parallels of these two places, by taking several stations and forming triangles; by means of which he found the degree to consist of 341,676 Leyden feet. Hence he assigned the round number 342,000 Leyden feet to a degree: which, according to Picard, amounts to 55,021 French toises. In 1635, Mr. Norwood, an Englishman, took the elevations of the pole at London and at York; and having measured the distance betwixt the two parallels, assigned 69½ miles and two poles to a degree; each pole being reckoned 16½ feet. After 1654, Ricciolus made use of several methods to determine the circumference of the earth; from all which he concluded, that one degree contained 64,363 Bologna paces, which are equivalent to 61,650 French toises. The most remarkable attempt, however, was that of the French mathematicians, who employed telescopic sights for the purpose, which had never been done before. These are much the best; as by them the view may be directed to an object at a greater distance, and towards any point with more certainty; whence the triangles for measuring distances may be formed with greater accuracy than otherwise can be done. In consequence of this improvement, the fundamental base of their operations was much longer than that made use of by Snellius or Ricciolus. The distance measured was between the parallels of Sourdun and Malvoisine; between which the difference of the polar altitude is somewhat more than one degree. The result of the whole, as related by Picard, was, that one degree contained 57,060 French toises. As this problem can be the more accurately determined in proportion to the length of the meridian-line measured, the members of the Royal Academy prolonged theirs quite across the kingdom of France, measuring it trigonometrically all the way. This work was begun in 1683, and finished in 1718. They used Picard's fundamental base, as being measured with sufficient accuracy; and an account of the whole was published by Cassini in 1720. In this work some mistakes were detected in the calculations of Snellius; and it was likewise shewn, that there are errors in those of Ricciolus owing principally to the latter having taken too short a fundamental base, and not having paid sufficient attention to the effects of refraction. Professor Muschenbroek was induced to make new calculations and form triangles upon the fundamental base of Snellius, which he did in 1700; and from these he assigns 57,033 toises to a degree, which is only 27 less than had been done by the academicians. In consequence of various opinions being entertained concerning the true figure of the earth, and the magnitude of a degree upon its surface, Messrs. Maupertuis, Clairaut, Camus, and Outheir, of France, were sent by Lewis XV. to measure an arch of the meridian in the northern regions of the earth. They began their operations, assisted by M. Celsus, an eminent astronomer of Sweden, in Swedish Lapland, in July 1736; and finished them by the end of May following. They obtained the measure of that degree whose middle-point was in lat. 66° 20' N. and found it to be 57,439 toises when reduced to the level of the sea. About the same time another company of philosophers were sent to South America, viz. Messrs. Godin, Bouguer, and Condamine, of France;

to whom were joined Don Jorge Juan, and Don Antonio de Ulloa, of Spain. They left Europe in 1735, and began their operations in the province of Quito in Peru, in October 1736, and finished them after many interruptions in about eight years. The Spanish gentlemen published a separate account, and assigned for a measure of a degree of the meridian, at the equator, 56,768 toises. M. Bouguer makes it 56,753 toises, when reduced to the level of the sea; and M. Condamine states it at 56,749 toises. M. La Caille, being at the Cape of Good Hope in 1752, found the length of a degree of the meridian in lat. 33° 18' 30" S. to be 57,037 toises. In 1755, Father Boscovich found the length of a degree in lat. 43° to be 56,972 toises, as measured between Rome and Rimini in Italy. In 1740, Messrs. Cassini again examined the former measures in France; and, after making all the necessary corrections, found the measure of a degree whose middle-point is in lat. 49° 22' N. to be 57,074 toises; and in the lat. of 45° it was 57,050 toises. In 1764, F. Beccaria, having measured a portion of the meridian near Turin, found the length of a degree whose middle-point was 44° 44' N. to be 57,024 toises. At Vienna three degrees of the meridian were measured, from which it may be concluded that a degree in lat. 47° 40' N. may be reckoned to be 57,091 Paris toises. In 1766, Messrs. Mason and Dixon measured a part of the meridian in Maryland and Pennsylvania, and found that the length of a degree whose middle-point is 39° 12' N. was 363,763 English feet, or 56,904½ toises. The improvements in geography, which have taken place in the more modern times, were owing to the great progress made in astronomy by Copernicus, Galileo, Newton, and other eminent men who lived within these three last centuries. More correct methods and instruments for observing the latitude were found out; and the discovery of Jupiter's satellites afforded a much easier method of finding the longitudes than was formerly known. The voyages also made by celebrated navigators of different nations, which were now become much more frequent than formerly, brought to the knowledge of the Europeans a vast number of countries totally unknown to them before. The late voyages of Captain Cook, made by order of his Britannic Majesty, have contributed more to the improvement of geography, than any thing that has been done during the 18th century. To these may be added the voyage made by Vancouver to explore the N. W. coasts of America; and that of the unfortunate La Perouse in the South Sea: as well as the late important additions made to geographical knowledge by the discoveries made by Mr. Mungo Park, in his Travels in the interior Parts of Africa. On the whole the geography of the utmost extremities of the globe is now in a fair way of being much better known to the moderns, than that of the most adjacent countries was to the ancients: at least with regard to the sea-coasts of these countries; for, as to their internal geography, it is less known now than before, except in a very few places. Still however, it must be owned, that geography is a science even yet far from perfection. The maps of America and the eastern parts of Asia are, perhaps, more unfinished than any of the rest. Even the maps of Great Britain and Ireland till very lately were imperfect; and the great numbers of them, that are varied and republished, without any real improvement, confirm an observation made by Lord Bacon, that an opinion of plenty is one of the causes of want. The late Dr. Bradley was of opinion, that there were but two places in England whose longitude might be depended upon as accurately taken; and that these were the observatory at Greenwich, and Serburn castle, the seat of the earl of Macclesfield in Oxfordshire; and that their distance was one degree in space, or four minutes in time. Even this was found to be inaccurate, the distance in time being observed by the late transit of Venus to be only three minutes and 47 seconds. Before the late Trigonometrical Survey of Great Britain, the result of which is published in the Philosophical Transactions, hardly any two geographers agreed in the longitude of the Lizard; some making it 4° 40' from London; others 5°, and others 5° 14': while some enlarged it to 6°. Our best maps of foreign countries are therefore still to be considered as imperfect, where there will always be many things to be added and corrected, as future geographers may find time and opportunity. The chief works on geography among the moderns are Johannes de Sacrobosco, (or John Hallifax,) *De Sphæra*; Sebastian Munster's *Cosmographia Universalis*; Clavius, on the *Sphere of Sacrobosco*; Riccioli's *Geographia et Hydrographia Reformata*; Weigelius's *Speculum Terræ*; De Chales's *Geography*, in his *Mundus Mathematicus*;

Mathematicus; Cellarius's Geography; Cluverii Introductio in Universam Geographiam; Leibnecht's Elementa Geographiae Generalis; Stevenius's Compendium Geographicum; Wolfii Geographia, in his Elementa Matheseos; Busching's New System of Geography; Gordon's, Salmon's, and Guthrie's Grammars; Pinkerton's Geography; and, above all, Varenus's Geographia Generalis, with Jurin's additions, the most scientific and systematical of any geographical work.

GENERAL GEOGRAPHY.

The proper object of geography as above stated is the surface of the terraqueous globe, being a superficies nearly spherical, divided into a variety of parts denominated places, which are distinguished by characteristic properties. Geography then is the science by which places and their properties are ascertained. By places we understand the parts large and small, of which the surface of the earth consists, or into which it is divisible; from the largest continent, or ocean, kingdom, or state, to the smallest hill, house, or individual point, or spot of ground. The properties of places, or accidents, by which they are affected, are either terrestrial or celestial. The terrestrial properties are figure, dimensions, and situation. The figure or form of places is various. The dimensions threefold; circumference, length, and breadth. The situation of places is likewise threefold. The first sort regards the province and country to which it belongs, and the particular mountain, plain, river, or lake, whereon it stands: and this we call the historical situation, a knowledge of which may be obtained barely from history or report. The second kind is that which places have, considered in respect of one another, whence it is called the relative or mutual situation. The third sort regards the particular spot of the earth where any place stands independent of other places, whence it may be called the absolute situation. Of these two sorts of situations, the absolute is most excellent, because that being obtained you have the relative also: whereas, the knowledge of the relative situation does not make known the absolute. The absolute is known from the latitude and longitude. The whole of geography, in effect, turns upon the situation of places; for what is a representation or description of the earth, but a combination of situations, exhibited to view? What are the figure and dimensions of countries, but the result of particular situations? The celestial properties or affections are, the rising or setting of the stars, vicissitudes of light and darkness, lengths of days and nights, variety of shadows, cold and heat, seasons of the year, and other phenomena. Geography may be divided into Mathematical, Historical, and Technical.

1. **MATHEMATICAL GEOGRAPHY**, comprises that part of geography which it borrows from mathematics. The mathematical part is derived from Geometry and Astronomy, by the help of which places and their properties, especially the absolute and relative situations, are determined. Hence mathematical geography may be subdivided into Geometrical, by which distances and places are measured and their relative situations are fixed; and Astronomical, by which the absolute situations, and celestial properties, are determined.

2. **HISTORICAL GEOGRAPHY** comprizes the particulars which geography takes from history, or those accounts of places, which furnish a notitia of them, in whole or in part, as travels, voyages, chorographical and topographical descriptions, astronomical observations, geometrical admeasurements, &c. This part of geography serves to exhibit the divisions of the earth, and hence is divided into Natural, which considers the natural divisions, as continents, oceans, peninsulas, seas, islands, &c. and Political, which considers the different countries, and their divisions, whether civil or ecclesiastical.

3. **TECHNICAL GEOGRAPHY**, is that part which regards the form or manner of the description, and is subdivided into Representative, when places are represented on maps, or globes, &c. Synoptical when the description is alphabetically arranged by way of geographical tables, and Explanatory, when the description is given in regular treatises for that purpose.

1. MATHEMATICAL GEOGRAPHY.

This, as already observed, is either geometrical, or astronomical. Geometrical geography, is chiefly employed in ascertaining the dimensions, distances, and relative situations, of places, and is

of excellent use in delineating roads, and the windings, and course of rivers, measuring the magnitudes of mountains, taking surveys and plans of particular parts of countries, and determining a variety of similar matters, which cannot be done by astronomical methods, and thus it includes surveying, and the measuring of heights and distances. See **MENSURATION**. This part of Geography is also employed in the construction of maps and globes, of which we shall treat in this article. For the different measures employed, See **MEASURE**.

ASTRONOMICAL GEOGRAPHY, is an important branch of this science, since by it the absolute situations of places are fixed, the form and magnitude of the earth determined, and the celestial properties of places exhibited: we shall therefore consider this part under separate heads as follows:

OF THE FIGURE AND MAGNITUDE OF THE EARTH.

The Earth is one of the great bodies which compose the planetary system. It moves round the sun in an orbit nearly circular, and completes its revolution in the course of a year, while at the same time it revolves continually upon its own axis, which is inclined to the plane of its orbit at an angle of $66\frac{1}{2}$ degrees; the time of a revolution being 23 hours and $56\frac{1}{2}$ minutes. The revolution of the earth round the sun is called its annual motion, and the rotation it performs on its own axis is called its diurnal motion. While the earth revolves round the sun in the course of its annual motion, its axis, round which the diurnal motion is constantly performed, moves always parallel to itself. It is by the parallelism of the axis, and the annual motion of the earth, that the changes of the seasons are produced. See **ASTRONOMY**, where this subject is treated at large, and the figure of the earth shewn to be that of an oblate spheroid excepting a few inequalities which are inconsiderable in comparison of the bulk of the earth. We shall only add, therefore, on this head the following Table of the dimensions of the earth which is given by Dr. Hutton:

The diameter	7,957 $\frac{1}{2}$ English miles.
The circumference	25,000 English miles.
A degree contains	69 $\frac{1}{2}$ English miles.
The superficies	193,944,206 square miles.
The solidity	263,930,000,000 cubic miles.

OF THE CIRCLES SUPPOSED TO BE DESCRIBED ON THE EARTH'S SURFACE.

In geography the circles, which the sun apparently describes in the heavens, are supposed to be extended as far as the earth, and marked on its surface. In like manner we may imagine as many circles as we please to be described on the earth, and their planes to be extended to the celestial sphere, till they mark concentric ones on the heavens. The most remarkable of those supposed by geographers to be described in this manner are the following:

The **AXIS** of the earth is that imaginarily line passing through the earth's centre, round which it continually revolves, from west to east.

The **POLES** of the earth are the points at which the axis meets the earth's surface. One of these is called the north pole, and the other the south pole. These correspond to the poles of the heavens, or the points where the earth's axis, when produced, meets the starry sphere.

The **EQUATOR** is a great circle on the earth's surface, equally distant from both poles, and corresponds to the equinoctial circle in the heavens. It divides the earth's surface into two equal portions called the northern and southern hemispheres. The equator is also sometimes called the Line, or Equinoctial Line.

The distance of any place, northward or southward from the equator, is called its **LATITUDE**, and is reckoned in degrees and minutes, &c. The distance between the poles and equator, which is a quadrant of a great circle passing through the poles, has by all geographers hitherto been supposed to be divided into 90 degrees; and each of these again subdivided into 60 minutes, &c. But some French astronomers, and in particular La Place, in his Exposition du Systeme du Monde, as well as in his *Traité de Mécanique Celeste*, has adopted the decimal division of the meridian. They have supposed the distance between the equator and the poles to be divided into 100 degrees, and each degree to be subdivided into 100 minutes, each minute into 100 seconds, and so on. All places lying on the north side of the equator are said to have

have north latitude: on the contrary, all places on the south side of the equator are said to have south latitude.

PARALLELS OF LATITUDE are less circles upon the earth's surface parallel to the equator. They may be considered as indefinite in number; all places that lie directly east or west from each other, are said to lie in the same parallel of latitude.

The **TROPICS** are two less circles on the earth, parallel to the equator, and $23\frac{1}{2}$ degrees distant from it. That which lies on the north side of the equator is called the Tropic of Cancer; and that which lies on the south side is called the Tropic of Capricorn. These circles correspond to the circles of the same name, which limit the sun's north and south declination from the equinoctial in the heavens.

The **POLAR CIRCLES** are two less circles upon the earth's surface, parallel to the equator. They are as far distant from the poles, which they surround, as the tropics are from the equator. That which lies toward the north pole is called the Arctic Circle, and that which lies next to the south pole is called the Antarctic Circle. To these there are corresponding circles, bearing the same names, in the heavens.

Great circles passing through the poles of the earth, and therefore perpendicular to the equator, are called **MERIDIANS**. The meridian passing through any particular place, lies in the plane of the celestial meridian of that place. It also divides the surface of the earth into two equal portions, called the eastern and western hemispheres, in respect of that place. The meridians may be considered as indefinite in number; and all places lying directly north and south from each other, are upon the same meridian. Sometimes by the meridian of a place is understood the half of a great circle, passing through that place, and extending from the one pole to the other; and the other half of the circle is called the opposite meridian. If we suppose 12 great circles, one of which is the meridian of a given place, to intersect each other at the poles of the earth, and divide the equator into 24 equal parts, these are the Hour or Horary circles of that place. These are by the poles divided into 24 semicircles, corresponding to the 24 hours of the day and night. The distance between each two of these semicircles is 15° , being the 24th part of 360.

The **LONGITUDE** of any place on the earth is an arc of the equator intercepted between the meridian passing through that place and some other meridian previously agreed upon, which is called the first meridian. The longitude is reckoned eastward and westward from the first meridian, by which means all places lying in the hemisphere to the eastward of that place, through which the first meridian passes, will have east longitude; and all places lying in the hemisphere to the westward of that place, will have west longitude. Geographers at different periods, and in different countries, have fixed upon different places for the first meridian. The rule among the ancients was to make it pass through the place farthest to the west that was known. But the moderns, knowing that no place on the earth can be considered the most westerly, have laid aside that method of reckoning the longitude. Ptolemy assumed the meridian that passes through the farthest of the Canary Islands, as his first meridian. After him, as more countries were discovered in that quarter, the first meridian was removed farther off. The Arabian geographers fixed the first meridian upon the utmost shore of the western ocean. Some fixed it to the island of St. Nicholas, near Cape Verd; Hondius to the isle of St. James; others to the isle Del Corvo, one of the Azores, because there the magnetic needle pointed due north at that time, and it was not then known, that the deviation of the needle from the true north is itself subject to variation. The latest geographers, particularly the Dutch, have pitched upon the Peak of Teneriffe; others on the Isle of Palm, one of the Canaries; and lastly the French, by order of the king, on the island of Ferro, another of the Canaries. But without regarding any of these rules, geographers and map-makers often assume the meridian of the place where they live, or the capital of their own country, or its chief observatory, for a first meridian. Hence in Great-Britain, we reckon the longitudes of places eastward and westward from the meridian of London, and sometimes those of places in Scotland from that of Edinburgh.

The **HORIZON** of a place is either sensible or rational. The **SENSIBLE HORIZON** of any place is a circle of the sphere, the plane of which touches the spherical surface of the earth at that place.

The **RATIONAL HORIZON** is a great circle of the sphere, the plane of which passes through the centre of the earth, and is parallel to the plane of the sensible horizon. Although the sensible and rational horizons have been defined as two distinct circles of the sphere, yet seeing that their planes, when produced to the sphere of the fixed stars, are only distant from each other by the earth's semidiameter, it is evident that these circles of the sphere may be supposed, as to sense, to coincide; for not only the earth's semidiameter, but even the orbit it describes round the sun, subtends no sensible angle at the distance of the nearest of the fixed stars. The horizon divides the celestial sphere into two equal portions or hemispheres; one of these is visible, but the other, by reason of the interposed body of the earth, is invisible.

By the **SENSIBLE HORIZON** of a place is also sometimes understood a circle, which determines the segment of the surface of the earth, which is visible to the eye; called also the **VISIBLE HORIZON**. It is evident that this circle will be most accurately defined at sea, and equally distant every where from the eye of an observer, but below the level of his eye. It will also be so much the more extensive, as the eye is raised above the earth's surface.

The **ZENITH** of a place is the point of the heavens directly over the head of an observer; and the **NADIR** is the point in the opposite hemisphere, directly under his feet; or the zenith and nadir are the poles of the horizon.

Great circles of the sphere passing through the zenith and nadir are called **VERTICAL CIRCLES**, or **AZIMUTHS**. They are also sometimes called **Secondaries** of the horizon; and in general any great circle passing through the poles of another is called its **secondary**. That vertical circle, which has its plane perpendicular to the plane of the meridian, is called the **PRIME VERTICAL**. The meridian and prime vertical, by their intersections with the horizon divide it into four equal parts. The points of their intersection are called the **CARDINAL POINTS**. The meridian cuts the horizon at right angles in the north and south points, and the prime vertical cuts it at right angles in the east and west points.

Less circles of the sphere parallel to the horizon are called **PARALLELS OF ALTITUDE** or **ALMACANTERS**. These parallels, as well as the vertical circles, may be considered as indefinite in number.

The circles in the heavens, which correspond with these are particularly described under the article **ASTRONOMY**, by a reference to a figure. See **ASTRONOMY**, Index.

OF THE METHODS OF FINDING THE LATITUDE AND LONGITUDE OF PLACES.

The figure and magnitude of the earth being known, it next becomes a problem of the utmost importance in geography, to determine the position of any assigned place upon its surface. This is done by finding its latitude and longitude: for by the first of these is determined the position of the parallel of latitude, which passes through that place; and by the second the position of its meridian; and thus the position of the place itself becomes known. Let PZEQ, Plate LXXXI. fig. 1, represent the celestial meridian, P the pole of the heavens, EQ the equinoctial, and HO the horizon; let pLe represent the terrestrial meridian, p the pole, and eq the equator: let L be any place on the earth, the latitude of which is to be found, and Z its zenith: the arch eL , which is the latitude of the place, evidently contains the same number of degrees as the arch EZ , which is the distance of the equinoctial from the zenith. Now ZO and PE are both quadrants; wherefore the arches, PO and ZE , are equal; but the arch PO is the elevation of the pole above the horizon. Thus it appears, that the latitude of a place is equal to the elevation of the pole above the horizon of that place. And hence by observing the altitude of the pole, the latitude of the place is ascertained from the observation. There is no star exactly in the pole of the world; but the elevation of the pole may be found by the pole-star, which is very near the pole, or by any other circumpolar star in this manner: let the altitude of the star be taken when it is on the meridian, both above and below the pole, by means of a quadrant or other proper instrument, making the proper corrections for the refraction of the atmosphere: then, half the sum of these altitudes, reckoned from the north, will be the elevation of the pole, or the latitude of the place at which the observation is made: for let S be the place of the star when above the pole, and s its place below the pole, then since $PS = Ps$, it is evident that PO is equal to half the sum of OS

OS and Os. Another method is by means of the declination of the sun, or a star, and one meridian-altitude of the same; thus: having, by means of a quadrant or other instrument, found the zenith-distance, Zd , of the luminary, or else its altitude, Hd , and taken its complement, Zd ; then, to this distance add the declination dE , as found by astronomical tables, when the luminary and place are on the same side of the equator, or subtract it when they are on different sides, and the sum or difference will be the latitude EZ sought. By either of these methods, and by many others that could be mentioned, the latitude may be found very accurately. While the earth revolves on its axis from W. to E. the different terrestrial meridians, which are considered as fixed to its surface, are turned in succession towards the sun; and it is noon-day at any place when the plane of the meridian of that place passes through his centre; at which time the sun, as seen from that place, appears to be due S. or N. according as the place happens to be situated to the N. or S. of the parallel of declination, which he describes that day in the heavens. Hence it appears, that all places situated on the same meridian will have their noon at the same instant of time; and that it will be forenoon to all places situated to the W. of that meridian, seeing that the meridians of these places have not yet passed the sun's centre; while on the contrary, it will be afternoon to all places situated to the E. of the meridian passing through the sun, seeing that the meridians of these places have already passed his centre. Since the planes of all the terrestrial meridians pass, one after another, through the sun in 24 hours, it follows: that in one hour the meridians of two places, whose difference of longitude is one-24th of 360° , or 15° , will have arrived at the sun's centre; and therefore, when it is noon at any place it will want one hour from noon at all places upon the meridian 15° to the W. of the meridian of that place, and two hours at all places 30° to the W. and so on till we come to the opposite meridian; where the difference of longitude is 180° , at which place it will then be midnight. The contrary happens with respect to places situated to the eastward of the given meridian; for at these places it is past noon, by the same part of 24 hours that the difference between their longitudes, and that of the meridian where it is then noon, is of 360° . The difference between the times of noon, and therefore of all the other hours of the day, at different places of the earth, is the foundation of the methods by which the longitude of any place is found. Suppose that some remarkable phenomenon were to be seen in the heavens, at the same instant of time, throughout all places in that hemisphere of the earth from which the phenomenon was then visible; it is evident from what has been said, that the time of its appearance would be different at different places, according as these meridians happened to be situated in respect of that phenomenon; and that if we knew the longitude of any place, as reckoned from some given meridian where the phenomenon was visible, we should be able to tell the difference between the time of its appearance, as reckoned at that place, and upon the given meridian. Suppose, for example, that the phenomenon was visible at 10 P. M. at some place upon the given meridian, and that another place was 30° of longitude W. from that meridian; then the phenomenon would be seen at 8 P. M. as reckoned at that place. Hence it follows on the contrary, that if we know the times of the appearance of the phenomenon, as reckoned at both these places, we shall also know how many degrees of longitude the one place is eastward or westward from the other. If, for example, it is seen at 9 P. M. at any one place, and at midnight at another place, we may be assured, that the latter place is 45° of longitude E. from the former. In this way may the longitudes of all places upon the earth's surface be found. The celestial phenomena to be observed at these places are eclipses of the sun and moon; eclipses of Jupiter's satellites, and particularly of his first satellite; occultations of the fixed stars by the moon and the planets; and lastly, the angular distance of the moon from the sun, and from the fixed stars.

The eclipses of JUPITER'S SATELLITES, which frequently happen, and which may be observed on shore, would afford to the navigator an easy method of finding his longitude, if it were also possible to observe them at sea; but the attempts that have been made to overcome the difficulties attendant on such observations, by reason of the motions of the vessel, have been hitherto unsuccessful. Navigation and geography have however received great

advantages from these eclipses; more especially from the eclipses of the first satellite, the commencement and the end of which can be observed with precision. It is indeed necessary to know also the hour at which any observed eclipse may be seen under a known meridian; seeing that it is by the difference of these hours that the longitude is found: but the tables of the first satellite are now brought to such a degree of perfection, as to give the times of these eclipses with a precision almost equal to that of the observations themselves. The great difficulty of observing these eclipses at sea has rendered it necessary to recur to other celestial phenomena; and of these the motions of the moon are the only ones that can be generally useful for the determination of the longitude. The position of the moon, as it would appear if seen from the centre of the earth, may easily be found at any time, by taking its angular distances from the sun or stars by a proper instrument. These being found, the tables of her motion give the hour as reckoned at the first meridian, when she ought to have had that position: by a comparison of this time, with the time as reckoned on board of the vessel when the observation was made, the navigator is enabled to determine his longitude. By such observations the longitudes and latitudes of a great number of places have been determined, and the position and extent of many countries accurately defined, concerning which the most erroneous opinions formerly were entertained. Much, however, yet remains to be done: the interior parts of Africa and America are yet in a great measure entirely unknown, and even many places frequently visited by navigators may have their positions more accurately determined than has been hitherto done. Besides the methods of finding the longitude already treated of, there is yet another much used by navigators; to whom an exact knowledge of their position, when at sea, and without any other guide than the stars and compass, is of the utmost importance. It has been already observed, that in order to know the longitude of any place, it is only necessary to know the difference between the time of noon, or of any other hour, at that place, and the time of noon, or of the same hour, at any place upon the first meridian; for from this difference of time the longitude may be found, by allowing 15° of longitude for every hour of time, and so in proportion for any period less than an hour. Hence it appears, that if a traveller, or navigator, set out from the first meridian, and carry with him a watch, or time-keeper, so regulated as to shew exactly the hours as reckoned at the first meridian; by comparing the time shewn by his watch with the time as reckoned at any place he may visit, or as found by means of proper astronomical observations at that place, it is evident he may immediately find its longitude. If instead of departing from the first meridian, he had departed from any other meridian whose longitude from the first meridian was known, still it is obvious, that the longitude is to be found by the same method of observation. This method of finding the longitude would be the most simple of any, were it not a matter of great difficulty to construct time-keepers that shall go with perfect regularity; more especially on board of a ship, where they are continually exposed to changes of temperature as well as continual agitation. The difficulties that occur have however been overcome by perseverance and ingenuity; and watches have been constructed that have gone with great uniformity for many months. See LONGITUDE.

OF THE DIFFERENT POSITIONS OF THE SPHERE.

If we could suppose an inhabitant of the earth capable of living at either of the poles, he would have always one of the celestial poles in his zenith and the other in his nadir, the equator coinciding with the horizon. Hence all the celestial parallels are also parallel to the horizon; and hence a person, or people, are said to live in a parallel sphere, or to have a parallel horizon. Those who live under the equator have both poles in the horizon, all the celestial parallels cutting the horizon at right angles; whence they are said to live in a right sphere, or to have a right horizon. Those who live between either of the poles and the equator are said to live in an oblique sphere, or to have an oblique horizon; because the celestial equator cuts their horizon obliquely, and all the parallels in the celestial sphere have their planes oblique to that of the horizon. In this sphere some of the parallels intersect the horizon at oblique angles, some are entirely above it, and some entirely below it; all of them, however, so situated, that they would if extended obliquely intersect the plane of the horizon. The largest parallel,

parallel, which appears entire above the horizon of any place in N. latitude, is called by the ancient astronomers, the Arctic circle of that place. Within this circle, *i. e.* between it and the arctic pole, are comprehended all the stars which never set in that place, but are carried perpetually round the horizon, in circles parallel to the equator. The largest parallel, which is hid entirely below the horizon of any place in N. latitude, was called the Antarctic circle of that place by the ancients. This circle comprehends all the stars which never rise in that place, but are carried perpetually round below the horizon, in circles parallel to the equator. In a parallel sphere, however, the equator may be considered as both arctic and antarctic circles; for being coincident with the horizon, all the parallels on one side are entirely above it, and those on the other entirely below it. In an oblique sphere, the nearer any place is to either of the poles the larger are the arctic and antarctic circles, as being nearer to the celestial equator, which is a great circle. In a right sphere, the arctic and antarctic circles have no place; because no parallel appears either entirely above or below it. By the ancients the arctic circle was called *maximus semper apparentium*, and *circulus perpetuæ apparitionis*; the antarctic circle on the other hand, being named *maximus semper occultorum*, and *circulus perpetuæ occultationis*. By the arctic and antarctic circles, however, modern geographers in general understand two fixed circles, at the distance of 23½ degrees from the poles. These mark out the space all round the globe where the sun appears to touch the horizon at midnight in mid-summer, and to be entirely sunk below it in winter. According to the different positions of the globe with regard to the sun, the celestial bodies exhibit different phenomena to the inhabitants. Thus, in a parallel sphere, they appear to move in circles round the horizon; in a right sphere, they appear to rise and set as at present, but always in circles cutting the horizon at right angles; but in an oblique sphere, the angle varies according to the degree of obliquity, and the position of the axis of the sphere with regard to the sun. The phenomena thence arising will be sufficiently understood from what is said under the article ASTRONOMY. From thence we may easily perceive the reason of the sun's continual change of place in the heavens: but though it is certain that this change takes place every moment; it is imperceptible for some time, unless by very nice astronomical observations. Hence we may generally suppose the place of the sun to be the same for a day or two together, though in a considerable number of days it becomes exceedingly obvious to every body. When he appears in the celestial equator, his motion seems for some time to be in the plane of that circle, though it is certain that his place there is only for a single moment; and in like manner, when he comes to any other point of the heavens, his apparent diurnal motion is in a parallel drawn throughout. Twice a year he is in the equator, and then the days and nights are nearly equal all over the earth. This happens in March and September: after which, the sun proceeding either northward or south, according to the season of the year, and the position of the observer, the days become longer or shorter than the nights, and summer or winter comes on, as is fully explained under the article ASTRONOMY. The recession of the sun from the equator either northward or southward is called his Declination, and is either north or south according to the season of the year; and when this declination is at its greatest height, he is then said to be in the tropic. The space between the two tropics, called the Torrid Zone, extends in breadth 47 degrees of latitude all round the globe; and throughout the whole of that space the sun is vertical to some of the inhabitants twice a year, but to those who live directly under the tropics only once. Throughout the whole torrid zone also there is little difference between the length of the days and nights. The ancient geographers found themselves considerably embarrassed in their attempts to fix the northern tropic; for though they took a very proper method, namely, to observe the most northerly place where objects had no shadow on a certain day, yet they found that on the same day no shadow was cast for a space of no less than 300 stadia. The reason of this was, the apparent diameter of the sun; which being about half a degree, seemed to extend himself over as much of the surface of the earth, and to be vertical every where within that space. When the sun is in or near the equator, he seems to change his place in the heavens most rapidly; so that about the equinoxes one may very easily perceive the difference in a day or two: but as he approaches the tropics this apparent change becomes gradually

slower; so that for a number of days he scarce seems to move at all. The reason of this may easily be understood from a globe or any map on which the ecliptic is delineated: for by drawing lines through every degree of it parallel to the equator, we shall perceive them gradually approach nearer, and nearer each other, until at last, when we approach the point of contact betwixt the ecliptic and tropic, they can for several degrees scarce be distinguished.

METHOD OF FINDING THE LENGTH OF THE DAY, AND THE BEGINNING AND ENDING OF THE TWILIGHT.

As it is of considerable importance in geography to know the length of the day at any assigned place upon the earth, it will therefore be proper to shew the manner of finding the time of the rising and setting of the sun, or any other of the celestial bodies. Let PZES, Plate LXXXI. fig. 2, represent the celestial meridian of any place, P and S being the poles of the sphere; let EQ be the equator, and HOR the horizon, stereographically projected upon the plane of the meridian; let PCS represent the six o'clock hour-circle, and *mOn* the parallel of declination described by the sun or a star at any given day of the year; the point O being that in which it cuts the horizon; then *nO* represents half the arch described by the sun when above the horizon, and *Om* the half of the arch described when below the horizon. Let POS represent an hour-circle passing through the sun or star when in the horizon, and meeting the equator EQ in A; the arch EA of the equator intercepted between the meridian and hour-circle, being found, and converted into time (allowing 15° to an hour), will evidently give half the time that the sun or star remains above the horizon, as the arch AQ will give half the time it remains below the horizon. As the arch EC contains 90° and corresponds to six hours, it is only necessary to find the arch CA, which is called the sun's ascensional difference, it being the difference between his right ascension and his oblique ascension; and having converted it into time to add it to, or subtract it from six hours, according as the latitude of the place and of the sun's declination are of the same or of contrary names, that is, both N. or both S.; or the one N. and the other S. and the sum or difference shall be half the length of the day, as required. In the spherical triangle CAO, right-angled at A, we have AO, the complement of the sun's declination, to be found from astronomical tables, and the angle ACO the complement of the latitude of the place, in order to find AC, the right ascension. Hence from the principles of spherics we have the following proportion: As radius to the tangent of the latitude, so is the tangent of the sun's declination to the sine of the sun's ascensional difference required. When the sun is in the same hemisphere with any place, and his declination is equal to the complement of its latitude, which can only happen to places within the polar circles, then *mn* the parallel of declination will not cut the horizon, and consequently the sun will not set in those places during the time his declination exceeds the co-latitude; but when the sun and place are in opposite hemispheres, then he will never rise at that place so long as his declination exceeds the co-latitude, and hence it is easy to see how to find the time when the sun begins to shine constantly upon any given place within the polar circle; and also the time when that place begins to be wholly in the dark for a considerable time together. It has been observed in astronomy, that the twilight commences in the morning and ends in the evening, when the sun is 18° below the horizon. The time of its commencement, or ending, may be found by spherical trigonometry as follows: let Z be the zenith, P the pole of the sphere, and T the place of the sun, 18° below the horizon HR. In the spherical triangle PZT, we have PZ the distance of the pole from the zenith, which is equal to the co-latitude of the place, and PT the complement of the sun's declination; also ZT, the distance of the sun from the zenith, which, in this case, is always 90° + 18° or 108°. From these we are to find the hour-angle, ZPT, which may be had by the following proportion: Let $V = \frac{1}{2}$ perimeter of the triangle. Then as sine ZP × sine PT is to radius square, so is sine (V - ZP) × sine (V - PT) to the square of the sine of $\frac{1}{2}$ ZPT. The angle ZPT being turned into time will give the time from noon of the beginning or ending of the twilight.

OF THE DIVISION OF THE EARTH'S SURFACE INTO CLIMATES AND ZONES; AND THE DIRECTION OF THE SHADOWS OF BODIES.

From observing the diversity in the length of the days and night,

nights, the rising and setting of the sun, with the other phenomena already mentioned, the ancient geographers divided the surface of the earth into certain districts, which they called climates; and instead of the method of describing the situation of places by their latitude and longitude as we do now, they contented themselves with mentioning the climate in which they were situated. When more accuracy was required, they mentioned also the beginning, middle, and ending, of the climates. This distinction, however, was certainly very vague and inaccurate: for the only method they had for determining the difference was by the length of the day; and a climate, according to them, was such a space as had the day in its most northerly part half an hour longer than in the most southerly. For the beginning of their first climate, they took that parallel under which the day is twelve hours and three quarters long; those parts of the world which lie nearer the equator not being supposed to be in any climate; either because in a loose sense they may be considered as in a right sphere, or because they were unknown, or thought to be uninhabitable by reason of the heat. The northern climates were generally supposed to be seven; which must have an equal number of southern climates corresponding with them. The northern climates, according to the ancients, were as follows: 1. *Meroc*. 2. *Syene* in Egypt. 3. *Alexandria* in Egypt. 4. *Rhodes*. 5. *Rome*; or, according to others, a parallel drawn through the *Hellespont*. 6. The parallel passing through the mouth of the river *Boristhenes*. 7. The *Riphean* mountains. Each of these places was supposed to be in the middle of the climate; and as the southern parts of the globe were then very little known, the climates to the S. of the equator were supposed to be as far distant from that circle as the northern ones; in consequence of which they took their names from the latter. A parallel was said to pass through the middle of a climate, when the day under that parallel is a quarter of an hour longer than that which passes through the most southerly part. Hence it does not divide the space into two equal parts, but that part next the equator will always be the larger of the two; because the farther we recede from that circle, the less increase of latitude will be sufficient to lengthen the day a quarter of an hour. Thus, in every climate there are three parallels; one marking the beginning, the second the middle, and the third the ending, of the climate; the ending of one being always the beginning of another. Some of the ancients divided the earth by these parallels; others by a parallel did not mean a mere line, but a space of some breadth; and hence the parallel may be understood as the same with half a climate. This method of dividing the surface of the earth into climates, though now very much disused, has been adopted by several modern geographers. Some of these begin their climates at the equator, reckoning them by the increase of half an hour in the length of the day northward. Thus they go on till they come to the polar circles, where the longest day is twenty-four hours: betwixt these and the poles they count the climates by the increase of a natural day in the length of time that the sun continues above the horizon, until they come to one where the longest day is fifteen of ours, or half a month; and from this to the pole they count by the increase of half months or whole months, the climates ending at the poles where the days are six months long. The climates betwixt the equator and the polar circles are called *hour-climates*, and those between the polar circles and the poles *month-climates*. But in common language, we use the word *climate* in a very different sense; so that, when two different countries are said to be in different climates, we understand only that the temperature of the air, seasons, &c. are different. The division of the earth into zones has arisen from the various appearances of the sun, and the effects of his light and heat upon different parts of it. These are five in number: 1. The *torrid zone*, lying between the two tropics for a space of $46^{\circ} \frac{1}{2}$ of latitude, or $23^{\circ} \frac{1}{2}$ on each side of the equator, it being divided into two equal parts by the equator; and the inhabitants have the sun vertical to them twice a-year, excepting those who dwell under the tropics, to whom he is vertical only once. 2. The two *temperate zones* lie between the polar circles and the tropics, containing a space of $43^{\circ} 4'$ of latitude. And, 3. The two *frigid zones* lie between the polar circles and the poles. In these last the longest day is never below twenty-four hours; in the temperate zones it is never quite so much, and in the torrid zone it is never above 14. The zones are named from the degree of heat they were supposed to be subjected to. The torrid zone was supposed by the ancients to be uninhabitable by reason

of its heat; but this is now found to be a mistake, and many parts of the temperate zones are more intolerable in this respect than the torrid zone itself. Towards the polar circles, also, these zones are intolerably cold during winter. Only a small part of the northern frigid zone, and none of the southern, is inhabited. Some geographers reckoned six zones, dividing the torrid zone into two by the equator. When any parts of the heaven or earth are said to be on the right or left, we are to understand the expression differently according to the profession of the person who makes use of it: because according to that, his face is supposed to be turned towards a certain quarter. A geographer is supposed to stand with his face to the north, because the northern part of the world is best known. An astronomer looks towards the south, to observe the celestial bodies as they come to the meridian. The ancient augurs, in observing the flight of birds, looked towards the east; while the poets look towards the *Fortunate Isles*. In books of geography, therefore, by the right hand we must understand the east: in those of astronomy, the west; in such as relate to augury, the south; and in the writings of poets, the north; according to the following verses:

Ad Boream Terræ, sed Cœli mensor ad Austrum:
Præco Dei Exortum videt, Occasumque Poeta.

From the difference in the length and positions of the shadows of terrestrial objects, ancient geographers have given different names to the inhabitants of certain places of the earth; the reason of which will be easily understood from the following considerations. 1. As the sun in his apparent annual revolution never removes farther from the equator than twenty-three degrees and a half, none of those who live without that space, or beyond the tropics, can have that luminary vertical to them at any season of the year. 2. All who live between the tropics have the sun vertical twice a year, though not all at the same time. Thus to those who live directly under the equator, he is directly vertical in March and Sept. at the equinox. If a place is in 10° N. lat. the sun is vertical when he has 10° north declination; and so of every other place. 3. All who live between the tropics, have the sun at noon sometimes N. and sometimes S. of them. Thus, they who live in a place situated in 20° N. lat. have the sun at noon to the northward when he has more than 20° N. declination, and to the southward when he has less. 4. Such of the inhabitants of the earth as live without the tropics, if in the northern hemisphere, have the sun at noon to the S. of them, but to the N. if in the southern hemisphere. 5. When the sun is in the zenith of any place, the shadow of a man, or any upright object, falls directly upon the place where they stand, and consequently is invisible; whence the inhabitants of such places were called *Æscii*, or without shadows: those who live between the tropics, and have the sun sometimes to the N. and sometimes to the S. of them, have of consequence their shadows projecting N. at some seasons of the year, and S. at others; whence they were called *Amphiscii*, or having two kinds of shadows. They who live without the tropics have their noon-shadows always the same way; and are therefore called *Heteroscii*, that is, having only one kind of shadow. If they are in N. lat. the shadows are always turned towards the N. and if in the southern hemisphere, towards the S. When a place is so far distant from the equator that the days are twenty-four hours long or longer, the inhabitants were called *Periscii*, because their shadows turn round them. Names have likewise been given the inhabitants of different parts of the earth, from the parallels of latitude under which they live, and their situation with regard to one another. Thus, when two places are so near each other, that the inhabitants have only one horizon, or at least that there is no perceptible difference between them, the inhabitants were called *Synæci*, that is, near neighbours; the seasons, days, nights, &c. in both places being perfectly alike. Those who lived at distant places, but under the same parallel, were called *Periæci*, that is, living in the same circle. Those who are on the same side of the equator have the seasons of the year at the same time; but if on different sides, the summer-season of the one is the winter of the other; as explained under astronomy. Some writers, however, by the name of *Periæci*, distinguish those who live under opposite points of the same parallel, where the noon of the one is the midnight of the other. When two places lie under parallels equally distant from the equator, but in opposite hemispheres, the inhabitants were called *Antæci*. These have a similar increase of days and nights, and similar seasons, but in opposite months. According

According to some, the Antœci were such as lived under the same geographical meridian, and had day and night at the same time. If two places are in parallels equally distant from the equator, and in opposite meridians, the inhabitants were called Antichthones, with respect to one another, that is, living on opposite sides of the earth; or Antipodes, having their feet opposite to one another. When two persons are Antipodes, the zenith of the one is the nadir of the other. They have a like elevation of the pole, but it is of different poles: they have also days and nights alike, and similar seasons of the year; but they have opposite hours of the day and night, as well as seasons of the year. Thus, when it is mid-day with us, it is midnight with our Antipodes; when it is summer with us, it is winter with them, &c.

II. HISTORICAL GEOGRAPHY.

Since the divisions of the surface of the earth, concerning which this part of geography is principally employed, are either natural or political, this branch divides itself into two parts, natural and political; the first regarding those divisions formed by nature, that is, to speak properly, by the hand of the eternal Creator and Preserver of all things; the second regarding those divisions made by the inhabitants for the sake of government and order among the different communities of men.

NATURAL GEOGRAPHY.

The natural division of the surface of the globe is into sea and land; about three-fourths of the whole being occupied by water, although probably no where to a depth comparatively very considerable, at most of a few miles on an average. The remaining fourth consists of lands, elevated more or less above the level of the sea, interspersed in some parts with smaller collections of water, at various heights, and in a few instances somewhat lower than the general surface of the main ocean. Thus the Caspian Sea is said to be about three hundred feet lower than the ocean. The sea and land is each of them again variously divided into parts: the names and definitions now follow:

A **CONTINENT** is a large portion of the earth, which comprehends several countries that are not separated by any sea; such are Europe, Asia, Africa, and America.

An **ISLAND** is a part of the earth which is entirely surrounded by water; as Great Britain.

A **PENINSULA** is a tract of land almost surrounded with water, and is joined to a continent only by a narrow slip or neck; such is the Morea in Greece.

An **ISTHMUS**, or **NECK OF LAND**, is that part by which a peninsula is joined to a continent, or two continents together; as the isthmus of Suez, which joins Africa to Asia.

A **PROMONTORY**, or **CAPE**, is a high part of land which stretches into the sea; thus the Cape of Good Hope is a promontory.

An **OCEAN** is a vast collection of waters surrounding a considerable part of the continent; as the Atlantic.

A **SEA** is a smaller collection of waters; as the Black Sea.

A **GULF** is a part of the sea which is nearly surrounded by land; as the Gulf of Venice.

A **BAY** has a wider entrance than a gulf; as the Bay of Biscay.

A **STRAIT** is a narrow passage that joins two seas; as the Strait of Gibraltar, which joins the Mediterranean to the Atlantic.

A **LAKE** is a large collection of water entirely surrounded by land, having no visible communication with the sea; as the Caspian Lake in Asia.

A **RIVER** is a stream of water that has its source from a spring, which keeps constantly running till it falls into some other river, or into the sea.

There are two continents, the old and new, divided into four grand parts, or quarters. The old continent, or that known to the ancients, comprehends Europe, Asia, and Africa; and the new continent, or that lately discovered, is denominated America, which is divided into North and South America. Of these grand divisions of the earth we find Europe, Asia, North America, part of Africa and South America, in the northern hemisphere, the seas occupying almost all the southern. Some place Australasia, or New Holland, among the grand divisions, and very properly, as its great extent demands this distinction. If the whole earth be

conceived to be divided into one hundred parts, Europe contains two; Asia, seven; Africa, six; America, six; and Australasia, two; the remaining seventy-seven being sea; although some authors assign seventy-two parts only out of one hundred to the sea, and twenty-eight to the land. These proportions may be ascertained with tolerable accuracy, by weighing the paper made for covering a globe, first entire, and then cut out according to the terminations of the different countries; or, if still greater precision were required, the greater part of the continents might be divided into known portions of the whole spherical surface, and the remaining irregular portions only weighed. Or, in square miles, the whole earth contains nearly two hundred millions, the seas and parts imperfectly known contain about one hundred and fifty-four millions; Europe, four millions; Asia, fourteen millions; Africa, twelve millions; America, twelve millions; and Australasia, four millions. These several divisions of the earth, and their principal parts, dependent islands, &c. will be found treated of in alphabetical order in the course of this work. The waters are divided into five oceans, namely, the Northern, the Atlantic or Western, the Pacific or Eastern, the Indian, and the Southern. The Northern Ocean stretches to the northward of Europe, Asia, and America, towards the north pole. The Atlantic Ocean lies between the continents of Europe and Africa on the east, and America on the west, and is usually divided into two parts, one called the North Atlantic Ocean, and the other the South Atlantic or Ethiopic Ocean, and is three thousand miles wide. The Pacific Ocean, or, as it is sometimes called, the Great South Sea, is bounded by the western and north-west shores of America, and by the eastern and north-east shores of Asia, and is ten thousand miles wide. The Indian Ocean washes the shores of the eastern coasts of Africa, and those of the south of Asia, and is about three thousand miles wide. The Southern Ocean extends to the southward of Asia and America towards the South pole. Captain Cook penetrated farther towards this pole than any other circumnavigator of the globe. The general inclinations and levels of the continents are discovered by the course of their rivers. Of these the principal are the following, with the length of each, according to major Rennel's calculation, taking the length of the Thames for unity; the Amazon is fifteen and three-quarters; the Kian Kew, in China, fifteen and a half; the Hoango, thirteen and a half; the Nile, twelve and a half; the Lena, eleven and a half; the Amur, eleven; the Oby, ten and a half; the Jenisei, ten; the Ganges, its companion the Burrampooter, the river Ava, and the Volga, each nine and a half; the Euphrates, eight and a half; the Mississippi, eight; the Danube, seven; the Indus, five and a half; and the Rhine, five and a quarter. The principal chain of mountains in the eastern continent first constitutes the Pyrenees, and divides Spain from France, then passes through Vivarais and Auvergne, to join the Alps, and through the south of Germany to Dalmatia, Albania, and Macedonia; it is found again beyond the Euxine, under the names of Taurus, Caucasus, and Imaus, and goes on to Tartary and to Kamschatka. The peninsula of India is divided from north to south by the mountains of Gate, extending from the extremity of Caucasus to Cape Comorin. In Africa, Mount Atlas stretches from Pez to Egypt, and the mountains of the moon run nearly in the same direction: there is also a considerable elevation between the Nile and the Red Sea. In the new world, the neighbourhood of the western coast is in general the most elevated; in North America the Blue Mountains, or Stony Mountains, are the most considerable; and the mountains of Mexico join the Andes or Cordeliers, which are continued along the whole west coast of South America. There are several points in both hemispheres, from which we may observe rivers separating to run to different seas; such as Switzerland, Bjelosero, Tartary, Little Tibet, Nigritia or Guinea, and Quito. The highest mountains, are Chimboragoa, and some others of the Cordeliers in Peru; or perhaps Descabesado in Chili, Mont Blanc, and the Peak of Teneriffe. Chimboragoa is about seven thousand yards, or nearly four miles, above the level of the sea; Mont Blanc, five thousand, or nearly three miles; the Peak of Teneriffe about four thousand, or two miles and a quarter; Ophir, in Sumatra, is said to be five or six hundred feet higher. It has, however, been asserted, that some of the snowy mountains to the north of Bengal, are higher than any of those of South America. On the tops of some of the mountains of Quito, in Peru, the barometer stands at the height of fifteen inches only, and the air is reduced to half its usual density,

But none of these heights is equal to a thousandth part of the earth's semidiameter, and are no more than so many specks in respect of the whole. For an account of the situations, and other particulars relating to these general heads, we refer to the articles themselves.

POLITICAL GEOGRAPHY.

The artificial divisions of the earth, or those made for the regulation of society, are subject to continual changes on account of the revolutions, new regulations, &c. which are almost always going on in some parts of the earth. The natural divisions, it is true, are also continually changing from various causes, but these changes are slow, preserving a sort of regularity, and proceeding by almost imperceptible degrees. But with regard to political divisions, the case is quite otherwise, so that we frequently hear of the boundaries of an empire or kingdom being extended, or contracted, or of its being destroyed altogether, and some other erected in its stead. The political divisions are either civil or ecclesiastical. The civil divisions are primary, as monarchies, which are either empires or kingdoms; and common-wealths, or republics, which are either aristocracies or democracies. These different divisions are so denominated from the kind of government exercised in the country, or from that form which predominates; for the several kinds are frequently mixed: 2. Secondary, as electorates, principalities, dukedoms, counties, markgraviates, or marquises, palatinates, landgraviates, baronies, free-cities, archbishoprics, bishoprics, abbeys, &c. The ecclesiastical governments have the common name of hierarchies, that is, holy principalities; but as this kind of jurisdiction extends only over the consciences, not the bodies or properties, of people, they cannot properly be called dominions, except such as have temporalities annexed to them; they are denominated patriarchates, primacies, archbishoprics, bishoprics, deaneries, &c. An explanation of the several terms pertaining to civil and ecclesiastical geography will be found in their regular alphabetical order. We shall here only add a general review of the grand divisions of this class, which are treated of, and their subdivisions noticed in this work.

III. TECHNICAL GEOGRAPHY.

This part of the science relates to the method of exhibiting geographical descriptions, which is, 1. By means of geographical tables, giving an analytical view of the whole earth, or of some part of it. 2. By treatises giving a systematical account of the science, or describing places in alphabetical order. 3. By delineations of the earth, or of some part of it on plane or curve surfaces; these graphical representations are of considerable importance, and are called maps and globes, of which we shall now treat.

OF THE CONSTRUCTION AND USE OF MAPS.

A MAP is a plane figure representing the surface of the earth, or some part of it; being a projection of its globular surface, exhibiting countries, seas, rivers, mountains, cities, &c. in their due positions, or nearly so. Maps are either universal or particular.

UNIVERSAL, or GENERAL MAPS, are such as exhibit the whole surface of the earth, or the two hemispheres.

PARTICULAR, or PARTIAL MAPS, are such as exhibit some particular part or region of the earth.

Both kinds are usually called GEOGRAPHICAL or LAND-MAPS, as distinguished from HYDROGRAPHICAL, or SEA-MAPS; which represent only the seas and sea-coasts, and are properly called charts.

Maps are constructed by making a projection of the globe, or a part of it, either on the plane of some particular circle, or by the eye placed in some particular point, according to the rules of perspective, &c. of which there are several methods.

I. CONSTRUCTION OF GENERAL MAPS. A map of the world must represent two hemispheres; and both must be drawn upon the plane of that circle which divides the hemispheres.

i. The first method is to project each hemisphere upon the plane of some particular circle, by the rules of orthographic projection; (see PROJECTION of the SPHERE) forming two hemispheres on one common base or circle. When the plane of projection is that of a meridian, the maps will be the E. and W. hemispheres; the other meridians will be ellipses; and the parallel circles will be right lines. Upon the plane of the equinoctial, the meridians will be right lines, crossing in the centre, which will represent the pole; the parallels of latitude will be circles having that common centre; and the maps will be the northern and southern hemispheres. Fig. 1, Plate LXXX, is an orthographic projection of one of the hemispheres upon the plane of the meridian: and fig. 2, an orthographic projection of the northern hemisphere upon the plane of the equator. The fault of this way of

drawing maps is, that towards the outside the circles are too near each other; and therefore equal spaces upon the earth are represented by very unequal spaces in the map.

ii. Another method is to project the same hemispheres by the rules of stereographic projection: in which way all the parallels will be represented by circles, and the meridians by circles or right lines. (For the nature and properties of these projections, see PROJECTION OF THE SPHERE.) But here the contrary fault occurs; viz. the circles towards the outsides are too far asunder, and about the middle they are too near together. Fig. 3, is a stereographic projection of one of the hemispheres on the plane of the meridian: and fig. 4, of one on the plane of the equator.

iii. A third method is therefore adopted to remedy the faults of both the former methods: viz. 1. For the E. and W. hemispheres, describe the circle PENQ, fig. 5, Plate LXXX, for the meridian, or plane of projection; through the centre of which draw the equinoctial EQ, and axis PN perpendicular to it, making P and N the north and south poles. Divide the quadrant PE, EN, NQ, and QP, into nine equal parts, each representing ten degrees, beginning at the equinoctial EQ. Divide also CP and CN into nine equal parts, beginning at EQ; and through the corresponding points draw the parallels of latitude. Again divide CE and CQ into nine equal parts; and through the points of division, and the two poles P and N, draw circles, or rather ellipses, for the meridians. Thus the map will be prepared to receive the names of the principal countries, kingdoms, cities, &c. in the world. For the N. or S. hemisphere, draw A Q B E, fig. 6, for the equinoctial, dividing it into the four quadrants EA, AQ, QB, and BE; and each quadrant into nine equal parts; and through these points, from the centre C, draw lines for meridians, and the parallels of latitude; equidistant as in the figure. In this last method, equal spaces on the earth are represented by equal spaces on the map, as near as any projection will bear; for a spherical surface can no way be represented exactly upon a plane. Then the several countries, kingdoms, cities, seas, islands, sea-coasts, towns, &c. are to be marked in the map, according to their latitudes and longitudes. In filling up the map, all places representing land are filled with such cities, towns, rivers, hills, &c. as the countries contain; but the seas are left white; the shores adjoining to them being shaded. Large rivers are marked by strong or double lines, drawn winding in the form of those they represent; and small rivers are expressed by small lines. Different countries are best distinguished by different colours; at least the borders of them should be so distinguished. Forests are represented by small trees; and mountains are shaded to make them appear. Sands are denoted by numerous small points; and rocks under water by small crosses. The mariner's compass, with the thirty-two points representing the winds, is drawn in any void space.

II. CONSTRUCTION OF PARTICULAR MAPS.

To draw a map of any particular country, its extent must be known as to latitude and longitude: as, suppose Spain, lying between the N. latitude 36° and 44° , and extending from 10° to 23° of longitude; so that its extent from N. to S. is 8° and from E. to W. 13° . 1. Draw the line AB, fig. 7, for a meridian passing through the middle of the country; on this, set off 8° from B to A, taken from any convenient scale; A being the north and B the south point. Through A and B draw the perpendiculars CD, EF, for the extreme parallels of latitude. Divide AB into eight parts or degrees, through which draw the other parallels of latitude, parallel to the former. For the meridians, divide any degree in AB into 60 equal parts, or geographical miles. Then, because the length of a degree in each parallel decreases towards the pole, (as appears from the annexed Table,) take the number of miles answering to the latitude of B, which is $48\frac{1}{2}$ nearly, and set it from B, seven times to E, and six times to F; so is EF divided into degrees. Again, from the same table take the number of miles of a degree in the latitude A, viz. $43\frac{1}{2}$ nearly; which set off, from A, seven times to C, and six times to D. Then from the points of division in the line CD, to the corresponding points in the line EF, draw so many right lines for the meridians. Number the degrees of latitude up both sides of the map, and the degrees of longitude on the top and bottom. Also in some vacant place make a scale of miles; or of degrees, if the map represent a large part of the earth; to serve for finding the distances of places upon the map.

Then make the proper divisions and subdivisions of the country and having the latitudes and longitudes of the principal places, it will be easy to set them down in the map; for any town, &c. must be placed, where the circles of its latitude and longitude intersect. For instance, Gibraltar, whose latitude is $36^{\circ} 4' 44''$ and lon. $12^{\circ} 27'$ will be at G; and Madrid, whose lat. is $40^{\circ} 25' 18''$ and lon. $14^{\circ} 44'$ will be at M. In like manner, the mouth of a river must be set down; but to describe the whole river, the lat. and lon. of every turning must be marked down, and the towns and bridges by and under which it runs. And so for woods, forests, mountains, lakes, forts, &c. The boundaries will be described by setting down the most remarkable places on the sea-coast, and drawing a continued dotted line through them all. This method is very proper for small countries.

A TABLE,

Shewing how many minutes or geographical miles of the equator make a degree of longitude, at every degree of latitude.

D. L.	MILES.	D. L.	MILES.	D. L.	MILES.	D. L.	MILES.	D. L.	MILES.
1	59,99	19	56,73	37	47,92	55	34,41	73	17,54
2	59,97	20	56,33	38	47,28	56	33,55	74	16,53
3	59,92	21	56,01	39	46,62	57	32,67	75	15,52
4	59,86	22	55,63	40	45,95	58	31,79	76	14,51
5	59,77	23	55,23	41	45,28	59	30,90	77	13,50
6	59,67	24	54,81	42	44,75	60	30,00	78	12,48
7	59,56	25	54,38	43	43,88	61	29,09	79	11,45
8	59,42	26	53,93	44	43,16	62	28,17	80	10,42
9	59,26	27	53,46	45	42,43	63	27,24	81	9,38
10	59,08	28	52,97	46	41,68	64	26,30	82	8,35
11	58,89	29	52,47	47	40,92	65	25,36	83	7,32
12	58,68	30	51,96	48	40,15	66	24,41	84	6,28
13	58,46	31	51,43	49	39,36	67	23,45	85	5,23
14	58,22	32	50,88	50	38,57	68	22,48	86	4,18
15	57,95	33	50,32	51	37,76	69	21,50	87	3,14
16	57,67	34	49,74	52	36,94	70	20,52	88	2,09
17	57,37	35	49,15	53	36,11	71	19,54	89	1,05
18	57,06	36	48,54	54	35,26	72	18,55	90	0,00

As this table is calculated only to whole degrees, therefore, when the length of a degree of longitude is required on a parallel of latitude, consisting of degrees and minutes, we must use the following proportion, viz. As one degree = 60 minutes is to the difference between the minutes answering to a degree, in the next greater, and next less tabular latitude; so is the excess of the proposed latitude above the next less tabular latitude to a proportional part; which being subtracted from the miles answering to a degree of latitude, in the next greater tabular latitude, will give the minutes answering to a degree of longitude on the proposed parallel.

Examp. How many minutes of the equator make a degree of longitude in the latitude of the Royal Observatory at Greenwich, the latitude being $51^{\circ} 28' 40''$ N.—Solution $60 : 82 : 28' 40'' : 3917$, which subtracted from 37,76, gives 37,3683 for the answer required. *N.B.* If 37,3683 be multiplied by 69½, and the product divided by 60, the quotient will be the number of English miles contained in a degree of longitude in the latitude of Greenwich.

$37,3683 \times 69,5$
Thus $\frac{37,3683 \times 69,5}{60} = 43,2849$ English miles, or which is the

same thing, 43 miles, 61 yards, one foot, and 5,7 inches. Therefore a place situated 43 miles, 61 yards, one foot, and 5,7 inches, to the east or west of the Royal Observatory at Greenwich will be exactly one degree of longitude to the east or west of the said Observatory. 2. Maps of particular places, being portions of the globe, may be drawn after the same manner as the whole; i. e. either by the orthographic or stereographic projection of the sphere. But in partial maps, an easier method may be taken; thus: having drawn the meridian AB, fig. 7, and divided it into equal parts, as in the last method, draw lines through all the points of division perpendicular to AB, for the parallels of latitude; CD, EF, being the extreme parallels. Then, to divide these, set off the degrees in each parallel, diminished as directed for the two extreme parallels CD, EF, in the last method; and through all the correspond-

ing points draw the meridians, which will be curve lines; and which were right lines in the last method; because only the extreme parallels were divided by the table. This method is proper for a large tract, as Europe, &c. in which case the parallels and meridians need only be drawn to every five or 10 degrees. This method is much used in drawing maps; as all the parts are nearly of their due magnitude, but a little distorted towards the outside, from the oblique intersection of the meridians and parallels. 3. A third method may be adopted thus: Draw PB, Plate LXXXI, fig. 4, of a convenient length for a meridian: divide it into nine equal parts, and through the points of division, describe as many circles for the parallels of latitude, from the centre P, which represents the pole. Suppose AB, fig. 4, the height of the map; then CD will be the parallel passing through the greatest latitude, and EF will represent the equator. Divide the equator EF into equal parts, of the same size as those in AB, both ways, beginning at B. Divide also all the parallels into the same number of equal parts, but less, in proportion to the numbers for the several latitudes, as directed in the last method for the rectilinear parallels. Then through all the corresponding divisions, draw curve-lines, which will represent the meridians, the extreme ones being EC and FD. Lastly number the degrees of lat. and lon. and place a scale of equal parts, either of miles or degrees for measuring distances. This is a very good method of drawing large maps, and is called the Globular Projection; all the parts of the earth being represented nearly of their due magnitude, excepting that they are a little distorted on the outsides. The following is a convenient method to draw a map of a considerable part of the earth's surface: as a map of Europe, which extends from 36° to 72° north latitude, draw a base-line GH, fig. 5, in the middle of which erect a perpendicular, IP, and assume any distance for 10° of latitude. Let the point I be 30°, from which set off six of the assumed distances to P, which will be the north pole. Number the distances 40, 50, 60, &c. and on the centre, P, describe arcs passing through the points of divisions on the line IP, which will be parallels of latitude. Divide the space assumed for 10° of latitude into 60 parts, by some diagonal-scale. Look into the above table, for the number of miles answering to 30°, which is 51,96; take this from the scale, and set it off on the arc 30° from the centre-line both ways. Do the same for 40°, 50°, 60°, &c., and through the corresponding divisions on all the arcs draw curve-lines; which will represent the meridian. When the degrees of latitude and longitude are marked the thing is done. We shall here add a very easy and correct method of drawing particular maps, which may be formed by means of the common compasses and ruler. Thus suppose it were required to draw a map of some part of the earth, including six degrees, as from the 39th to the 45th parallel of latitude, draw the line EF, and in the middle raise a perpendicular DC. Divide this perpendicular into six equal parts, representing the degrees of latitude, and through C draw a line parallel to EF. Divide a degree into ten, or if large enough, into 60 equal parts; and in the table for decreasing longitudes, find the contents of a degree of longitude in the latitude of 39°, viz. 46,62 miles. From the degree so divided, take the parts 46,62; set one-half of it from D to E, and the other from D to F. Find then the extent of a degree of longitude in the latitude of 45°, viz. 42,43 miles; and taking that distance from the scale of the degree, divide it as before, laying one-half from C to I, and the other from C to K. Draw straight lines between the points I and E, and K and F; divide them into six equal parts, and through these draw parallel lines, and thus I K E F is a projection for one degree of longitude, and six of latitude. The projection of the whole map is only a repetition of this operation; we have therefore only to take, with a pair of compasses, the distance from E to K, from F to I, and setting one foot in E, and then in F, describe the arches L and M; and in like manner set one foot in I, and then in K, and with the same extent draw the arches N and O. Then take the distance between E and F, and set from E to N, and from F to O. Set likewise the distance between I and K, and from I to L, and from K to M. Join LN and MO, divide them into degrees, and draw parallels to these points to their corresponding points in the meridians IE and KF. After the same manner may meridians and parallels be drawn to as many degrees of longitude as your map contains. If the map be very large so that the compasses cannot take in the whole extent of the diagonal IF, or EK, we may do it at twice by taking the

diagonals GF, or EH, by transferring them as already directed; after which, we may do the same with the other half. When the place for which a map is to be drawn, is but small, e. g. if a county were to be exhibited, the meridians, as to sense, will be parallel to each other, and the whole will differ very little from a plane. Such a map may be made more easily than by the preceding rules, merely by measuring the distances in miles, and so laying them down in a plane rectangular map. But this branch of map-making belongs more properly to surveying, which see.

The Use of MAPS is obvious from their construction. The degrees of the meridians and parallels shew the latitudes and longitudes of places, and the scale of miles annexed, their distances; the situation of places, with regard to each other, as well as to the cardinal points, appears on inspection; the top of the map being always the north, the bottom the south, the right hand the east, and the left the west, unless the compass, usually annexed, shew the contrary.

DESCRIPTION OF THE TERRESTRIAL GLOBE.

The equator, ecliptic, and tropics, polar circles, and meridians, are laid down upon the globe in the manner already described. The ecliptic is divided into 12 signs, and each sign into 30 degrees. Each tropic is 23½ degrees from the equator, and each polar circle is 23½ degrees from its respective pole. Circles are drawn parallel to the equator, at every 10 degrees distance from it on each side of the poles: these circles are called parallels of latitude. On large globes there are circles drawn perpendicularly through every tenth degree of the equator, intersecting each other at the poles; but on the globes of or under a foot diameter, they are only drawn through every 15th degree of the equator: these circles are generally called meridians, sometimes circles of longitude, and at other times hour circles. The globe is hung in a brass-ring, A, fig. 3, plate LXXV. called the brazen meridian, and turns upon a wire in each pole sunk half its thickness into one side of the meridian-ring; by which means that side of the ring divides the globe into two equal parts, called the eastern and western hemispheres; as the equator divides it into two equal parts, called the northern and southern hemispheres. The ring is divided into 360 equal parts or degrees, on the side wherein the axis of the globe turns. One half of these degrees are numbered, and reckoned from the equator to the poles, where they end at 90. Their use is to shew the latitudes of places. The degrees in the other half of the meridian are numbered from the poles to the equator, where they end at 90. Their use is to shew how to elevate either the north or south pole above the horizon, according to the latitude of any given place, as it is N. or S. of the equator. The brazen meridian is let into two notches made in a broad flat ring called the wooden horizon, B, C; the upper surface of which divides the globe into two equal parts, called the upper and lower hemispheres. One notch is in the north point of the horizon, and the other in the south. On this horizon are several concentric circles, which contain the months and days of the year, the signs and degrees answering to the sun's place for each month and day, the 32 points of the compass, and the circles of amplitude and azimuth. The graduated side of the brass-meridian lies towards the east side of the horizon, and should be generally kept towards the person who works problems by the globes. There is a small horary circle D, so fixed to the north part of the brazen meridian, that the wire in the north pole of the globe is in the centre of that circle; and on the wire is an index, which goes over all the 24 hours of the circle, as the globe is turned round its axis. Sometimes there are two horary circles, one between each pole of the globe and the brazen meridian. There is a thin slip of brass, called the Quadrant of Altitude, which is divided into 90 equal parts or degrees, answering exactly to so many degrees of the equator. It is occasionally fixed to the uppermost point of the brazen meridian by a nut and screw. The divisions end at the nut E, and the quadrant is turned round upon it. A magnetic needle, is applied to the globe which freely moves over a circle divided into four times 90 degrees; reckoning from the N. and S. points towards the E. and W. and also into the 32 points of the compass. As this needle makes nearly a certain constant angle with the meridian in every place, called the variation; therefore this compass, being added to the frame, will rectify the position of the meridian of the globe when the variation of the needle is known. Thus at

London,

London, the variation of the needle is at this time about 24 degrees northwest; therefore, by moving the frame of the globe about till the needle settles itself over the 24th degree, reckoning westward from the north point or fleur de lis, we shall have the brass-meridian coinciding with the true meridian. The compass is sometimes fixed between the legs underneath the globe.

DIRECTIONS FOR USING THE TERRESTRIAL GLOBE.

In using globes, keep the east side of the horizon towards you (unless the problem requires to turn it,) which side may be known by the word East upon the horizon; for then you have the graduated side of the meridian towards you, the quadrant of altitude before you, and the globe divided exactly into two equal parts, by the graduated side of the meridian.

PROB. I. *To find the latitude and longitude of any given place upon the globe.*—Turn the globe on its axis, until the given place comes exactly under that graduated side of the brazen meridian on which the degrees are numbered from the equator; and observe what degree of the meridian the place then lies under; which is its latitude N. or S. as the place is N. or S. of the equator. The globe remaining in this position, the degree of the equator, which is under the brazen meridian, is the longitude of the place, which is E. or W.; as the place lies on the E. or W. side of the first meridian of the globe. All the Atlantic ocean and America, are on the W. side of the meridian of London; and the greatest part of Europe, and of Africa, together with all Asia, are on the E. side of the meridian of London, which is reckoned the first meridian of the globe by the British geographers and astronomers.

PROB. II. *The longitude and latitude of a place being given, to find that place on the globe.*—Look for the given longitude in the equator (counting it eastward or westward from the first meridian, as it is mentioned to be E. or W.;) and bringing the point of longitude in the equator to the brazen meridian, on that side which is above the south point of the horizon; then count from the equator, on the brazen meridian, to the degree of the given latitude, towards the N. or S. pole, according as the latitude is N. or S.; and under that degree of latitude on the meridian you will have the place required.

PROB. III. *To find the difference of longitude, or difference of latitude, between any two given places.*—Bring each of these places to the brazen meridian, and see what its latitude is: the less latitude subtracted from the greater, if both places be on the same side of the equator, or both latitudes added together, if they be on different sides of it, is the difference of latitude required. And the number of degrees contained between these places, reckoned on the equator, when they are brought separately under the brazen meridian, is their difference of longitude, if it be less than 180; but if more, let it be subtracted from 360, and the remainder is the difference of longitude required. Or,

Having brought one of the places to the brazen meridian, and set the hour-index to XII. turn the globe until the other place comes to the brazen meridian; and the number of hours, and parts of an hour, passed over by the index, will give the longitude in time; which may be easily reduced to degrees, by allowing 15 degrees for every hour, and one degree for every four minutes.

N. B. When we speak of bringing any place to the brazen meridian, it is the graduated side of the meridian that is meant.

PROB. IV. *Any place being given, to find all those places that have the same longitude or latitude with it.*—Bring the given place to the brazen meridian; then all those places which lie under that side of the meridian, from pole to pole, have the same longitude with the given place. Turn the globe round its axis: and all those places, which pass under the same degree of the meridian that the given place does, have the same latitude with that place. Since all latitudes are reckoned from the equator, and all longitudes are reckoned from the first meridian, it is evident, that the point of the equator which is cut by the first meridian, has neither latitude nor longitude. The greatest latitude is 90 degrees, because no place is more than 90 degrees from the equator; and the greatest longitude is 180 degrees, because no place is more than 180 degrees from the first meridian.

PROB. V. *To find the Antæci, Periæci, and Antipodes, of any given Place.*—Bring the given place to the brazen meridian; and having found its latitude, keep the globe in that situation, and count the same number of degrees of latitude from the equator to-

wards the contrary pole; and where the reckoning ends, you have the antæci of the given place upon the globe. Those who live at the equator have no antæci. The globe remaining in the same position, set the hour-index to the upper XII. on the horary circle, and turn the globe until the index comes to the lower XII.; then the place which lies under the meridian, in the same latitude with the given place, is the periæci required. Those who live at the poles have no periæci. As the globe now stands (with the index at the lower XII.) the antipodes of the given place will be under the same point of the brazen meridian where its antæci stood before. Every place upon the globe has its antipodes.

PROB. VI. *To find the distance between any two places on the globe.*—Lay the graduated edge of the quadrant of altitude over both the places, and count the number of degrees intercepted between them on the quadrant; then multiply these degrees by 60, and the product will give the distance in geographical miles: but to find the distance in miles, multiply the degrees by 69½, and the product will be the number of miles required. Or, take the distance betwixt any two places with a pair of compasses, and apply that extent to the equator; the number of degrees, intercepted between the points of the compasses, is the distance in degrees of a great circle: which may be reduced either to geographical miles, or to English miles, as above.

PROB. VII. *A place on the globe being given, and its distance from any other place; to find all the other places upon the globe, which are at the same distance from the given place.*—Bring the given place to the brazen meridian, and screw the quadrant of altitude to the meridian directly over that place; then keeping the globe in that position, turn the quadrant quite round upon it, and the degree of the quadrant that touches the second place will pass over all the other places, which are equally distant with it from the given place. This is the same as if one foot of a pair of compasses were set in the given place, and the other foot extended to the second place, whose distance is known; for if the compasses be then turned round the first place as a centre, the moving foot will go over all those places which are at the same distance with the second from it.

PROB. VIII. *The hour of the day at any place being given, to find all those places where it is noon at that time.*—Bring the given place to the brazen meridian, and set the index to the given hour; this done, turn the globe until the index points to the upper XII. and then all the places that lie under the brazen meridian have noon at that time.

N. B. The upper XII. always stands for noon; and when the bringing of any place to the brazen meridian is mentioned, the side of that meridian on which the degrees are reckoned from the equator is meant, unless the contrary side be mentioned.

PROB. IX. *The hour of the day at any place being given, to find what o'clock it is then at any other place.*—Bring the given place to the brazen meridian, and set the index to the given hour; then turn the globe, until the place where the hour is required comes to the meridian, and the index will point out the hour at that place.

PROB. X. *To find the sun's place in the ecliptic, and his declination for any given day of the year.*—Look on the horizon for the given day, and right against it you have the degree of the sign in which the sun is (or his place) on that day at noon. Find the same degree of that sign in the ecliptic-line upon the globe, and having brought it to the brazen meridian, observe what degree of the meridian stands over it; for that is the sun's declination reckoned from the equator.

PROB. XI. *The day of the month being given, to find all those places of the earth, over which the sun will pass vertically on that day.*—Find the sun's place in the ecliptic for the given day, and having brought it to the brazen meridian, observe what point of the meridian is over it; then, turning the globe round its axis, all those places which pass under that point of the meridian are the places required; for as their latitude is equal, in degrees and parts of a degree, to the sun's declination, the sun must be directly over-head to each of them at its respective noon.

PROB. XII. *A place being given in the torrid zone, to find those two days of the year, on which the sun shall be vertical to that place.*—Bring the given place to the brazen meridian, and mark the degree of latitude that is exactly over it on the meridian; then turn the globe round its axis, and observe the two de-

degrees of the ecliptic which pass exactly under that degree of latitude: lastly, find on the wooden horizon the two days of the year in which the sun is in those degrees of the ecliptic, and they are the days required: for on them, and none else, the sun's declination is equal to the latitude of the given place; and, consequently, he will then be vertical to it at noon.

PROB. XIII. *To find all those places of the north frigid zone, where the sun shines constantly without setting, on any given day, from the 21st of March to the 23d of September.*—On these two days, the sun is in the equinoctial, and enlightens the globe exactly from pole to pole: therefore, as the earth turns round its axis, which terminates in the poles, every place upon it will go equally through the light and the dark, and so make the day and night equal to all places of the earth. But as the sun declines from the equator, towards either pole, he will enlighten as many degrees round that pole as are equal to his declination from the equator: so that no place within that distance of the pole will then go through any part of the dark, and consequently the sun will not set to it. Now, as the sun's declination is northward from the 21st of March to the 23d of September, he must constantly shine round the north pole all that time; and on the day that he is in the northern tropic, he shines upon the whole north frigid zone; so that no place within the north polar circle goes through any part of the dark on that day. Therefore, having brought the sun's place for the given day to the brazen meridian, and found his declination, (by Prob. IX.) count as many degrees on the meridian, from the north pole, as are equal to the sun's declination from the equator, and mark that degree from the pole where the reckoning ends; then turning the globe round its axis, observe what places in the north frigid zone pass directly under that mark; for they are the places required. The like may be done for the south frigid zone, from the 23d of September to the 21st of March, during which time the sun shines constantly on the south pole.

PROB. XIV. *To find the place over which the sun is vertical at any hour of a given day.*—Having found the sun's declination for the given day (by Prob. X.) mark it with chalk on the brazen meridian: then bring the given place to the brazen meridian, and set the index to the given hour; which done, turn the globe on its axis, until the index points to XII. at noon; and the place on the globe, which is then directly under the point of the sun's declination marked upon the meridian, has the sun that moment in the zenith, or directly over head.

PROB. XV. *The day and hour of a lunar eclipse being given; to find all those places of the earth to which it will be visible.*—The moon is never eclipsed but when she is full, and so directly opposite to the sun, that the earth's shadow falls upon her. Therefore, whatever place of the earth the sun is vertical to at that time, the moon must be vertical to the antipodes of that place: so that the sun will be then visible to one-half of the earth, and the moon to the other. Find the place to which the sun is vertical at the given hour (by Prob. XIV.) and bring the antipodes of that place to the meridian, and elevate the pole to its latitude: then, the moon will be visible to all those parts of the globe which are above the horizon, at the time of her greatest obscuration.

PROB. XVI. *To rectify the globe for the latitude, the zenith, and the sun's place.*—Find the latitude of the place (by Prob. I.), and if the place be in the northern hemisphere, raise the north pole above the north point of the horizon, as many degrees (counted from the pole upon the brazen meridian) as are equal to the latitude of the place. If the place be in the southern hemisphere, raise the south pole above the south point of the horizon as many degrees as are equal to the latitude. Then, turn the globe till the place comes under its latitude on the brazen meridian, and fasten the quadrant of altitude so, that the chamfered edge of its nut (which is even with the graduated edge) may be joined to the zenith, or point of latitude. This done, bring the sun's place in the ecliptic for the given day (found by Prob. X.) to the graduated side of the brazen meridian, and set the hour-index to XII. at noon, which is the uppermost XII. on the hour-circle; and the globe will be rectified.

PROB. XVII. *The latitude of any place, not exceeding 66 $\frac{2}{3}$ degrees, and the day of the month, being given; to find the time of the sun's rising and setting, and consequently the length of the day and night.*—Having rectified the globe for the latitude; and

for the sun's place on the given day (as directed in the preceding problem), bring the sun's place in the ecliptic to the eastern side of the horizon, and the hour-index will shew the time of sun-rising; then turn the globe on its axis, until the sun's place comes to the western side of the horizon, and the index will shew the time of sun-setting. The hour of sun-setting doubled, gives the length of the day; and the hour of sun-rising doubled, gives the length of the night.

PROB. XVIII. *The latitude of any place, and the day of the month, being given; to find when the morning twilight begins, and the evening twilight ends, at that place.*—This problem is often limited: for, when the sun does not go 18 degrees below the horizon, the twilight continues the whole night; and for several nights together in summer, between 49 and 66 $\frac{2}{3}$ degrees of latitude; and the nearer to 66 $\frac{2}{3}$, the greater is the number of these nights. But when it does begin and end, the following method will shew the time for any given day. Rectify the globe, and bring the sun's place in the ecliptic to the eastern side of the horizon; then mark with chalk that point of the ecliptic which is in the western side of the horizon, it being the point opposite to the sun's place; this done, lay the quadrant of altitude over the said point, and turn the globe eastward, keeping the quadrant at the chalk-mark, until it is just 18 degrees high on the quadrant; and the index will point out the time when the morning-twilight begins: for the sun's place will then be 18 degrees below the eastern side of the horizon. To find the time when the evening-twilight ends, bring the sun's place to the western side of the horizon; and the point opposite to it, which was marked with the chalk, will be rising in the east: then bring the quadrant over that point, and keeping it thereon, turn the globe westward, until the said point be 18 degrees above the horizon on the quadrant, and the index will shew the time when the evening twilight ends; the sun's place being then 18 degrees below the western side of the horizon.

PROB. XIX. *To find on what day of the year the sun begins to shine constantly, on any given place in the north frigid zone; and how long he continues to do so.*—Rectify the globe to the latitude of the place, and turn it about until some point of the ecliptic, between Aries and Cancer, coincides with the north point of the horizon where the brazen meridian cuts it; then find, on the wooden horizon, what day of the year the sun is in that point of the ecliptic; for that is the day on which the sun begins to shine constantly on the given place without setting. This done, turn the globe, until some point of the ecliptic, between Cancer and Libra, coincides with the north point of the horizon, where the brazen meridian cuts it; and find, on the wooden horizon, on what day the sun is in that point of the ecliptic; which is the day that the sun leaves off constantly shining on the said place, and rises and sets to it as to other places on the globe. The number of natural days, or complete revolutions of the sun about the earth, between the two days above found, is the time that the sun keeps constantly above the horizon without setting: for all that portion of the ecliptic, which lies between the two points which intersect the horizon in the very north, never sets below it; and there is just as much of the opposite part of the ecliptic that never rises; therefore the sun will keep as long constantly below the horizon in winter as above it in summer.

PROB. XX. *To find in what latitude the sun shines constantly, for any length of time less than 182 $\frac{1}{2}$ of our days and nights.*—Find a point in the ecliptic half as many degrees from the beginning of Cancer (either toward Aries or Libra) as there are natural days in the time given; and bring that point to the north side of the brazen meridian, on which the degrees are numbered from the pole towards the equator: then keep the globe from turning on its axis, and slide the meridian up or down, until the foresaid point of the ecliptic comes to the north point of the horizon, and then the elevation of the pole will be equal to the latitude required.

PROB. XXI. *The latitude of a place, not exceeding 66 $\frac{2}{3}$ degrees, and the day of the month, being given; to find the sun's amplitude or point of the compass, on which he rises or sets.*—Rectify the globe, and bring the sun's place to the eastern side of the horizon; then observe what point of the compass on the horizon stands right against the sun's place, for that is his amplitude at rising. This done, turn the globe westward, until the sun's place

place comes to the western side of the horizon; and it will cut the point of his amplitude at setting. Or, you may count the rising-amplitude in degrees, from the east point of the horizon to that point where the sun's place cuts it; and the setting-amplitude from the west point of the horizon to the sun's place at setting.

PROB. XXII. *The latitude, the sun's place, and his altitude, being given; to find the hour of the day, and the sun's azimuth, or number of degrees that he is distant from the meridian.*—Rectify the globe, and bring the sun's place to the given height upon the quadrant of altitude; on the eastern side of the horizon, if the time be in the forenoon; or the western side, if it be in the afternoon: then the index will shew the hour; and the number of degrees in the horizon, intercepted between the quadrant of altitude and the south point, will be the sun's true azimuth at the time.

PROB. XXIII. *The latitude, hour of the day, and the sun's place, being given; to find the sun's altitude and azimuth.*—Rectify the globe, and turn it until the index points to the given hour; then lay the quadrant of altitude over the sun's place in the ecliptic, and the degree of the quadrant cut by the sun's place is his altitude at that time above the horizon; and the degree of the horizon cut by the quadrant is the sun's azimuth, reckoned from the S.

PROB. XXIV. *The latitude, the sun's altitude, and his azimuth, being given; to find his place in the ecliptic, the day of the month, and the hour of the day, though they had all been lost.*—Rectify the globe for the latitude and zenith, and set the quadrant of altitude to the given azimuth in the horizon; keeping it there, turn the globe on its axis until the ecliptic cuts the quadrant in the given altitude; that point of the ecliptic which cuts the quadrant there will be the sun's place; and the day of the month answering thereto will be found over the like place of the sun on the wooden horizon. Keep the quadrant of altitude in that position; and, having brought the sun's place to the brazen meridian, and the hour-index to XII. at noon, turn back the globe, until the sun's place cuts the quadrant of altitude again, and the index will shew the hour. Any two points of the ecliptic, which are equi-distant from the beginning of Cancer or of Capricorn, will have the same altitude and azimuth at the same hour, though the months be different; and therefore it requires some care in this problem, not to mistake both the month and the day of the month; to avoid which, observe, that from the 20th of March to the 21st of June, that part of the ecliptic which is between the beginning of Aries and the beginning of Cancer is to be used; from the 21st of June to the 23d of September, between the beginning of Cancer and beginning of Libra; from the 23d of September to the 21st of December, between the beginning of Libra and the beginning of Capricorn; and from the 21st of December to the 20th of March, between the beginning of Capricorn and beginning of Aries. And as one can never be at a loss to know in what quarter of the year he takes the sun's altitude and azimuth, the above caution with regard to the quarters of the ecliptic will keep him right as to the month and day thereof.

PROB. XXV. *To find the length of the longest day at any given place.*—If the place be on the N. side of the equator, find its latitude (by Prob. I.) and elevate the north pole to that latitude; then bring the beginning of Cancer to the brazen meridian, and set the hour-index to XII. at noon. But if the given place be on the S. side of the equator, elevate the south pole to its latitude, and bring the beginning of Capricorn to the brass meridian, and the hour-index to XII. This done, turn the globe westward, until the beginning of Cancer or Capricorn (as the latitude is N. or S.) comes to the horizon; and the index will then point out the time of sun-setting, for it will have gone over all the afternoon-hours, between mid-day and sun-set; which length of time being doubled, will give the whole length of the day from sun-rising to sun-setting. For, in all latitudes, the sun rises as long before mid-day as he sets after it.

PROB. XXVI. *To find in what latitude the longest day is of any given length less than 24 hours.*—If the latitude be N. bring the beginning of Cancer to the brazen meridian, and elevate the north pole to $66\frac{1}{2}$ degrees; but if the latitude be S. bring the beginning of Capricorn to the meridian, and elevate the south pole to $66\frac{1}{2}$ degrees; because the longest day in N. latitude is,

when the sun is in the first point of Cancer; and in S. latitude, when he is in the first point of Capricorn. Then set the hour-index to XII at noon, and turn the globe westward, until the index points at half the number of hours given; which done, keep the globe from turning on its axis, and slide the meridian down in the notches, until the aforesaid point of the ecliptic (viz. Cancer or Capricorn) comes to the horizon; then the elevation of the pole will be equal to the latitude required.

PROB. XXVII. *The latitude of any place, not exceeding $66\frac{1}{2}$ degrees, being given; to find in what climate the place is.*—Find the length of the longest day at the given place, (by Prob. XXV.) and whatever be the number of hours whereby it exceedeth twelve, double that number, and the sum will give the climate in which the place is.

PROB. XXVIII. *The latitude, and the day of the month, being given; to find the hour of the day, when the sun shines.*—Set the wooden horizon truly level, and the brazen meridian due N. and S. by a mariner's compass; then, having rectified the globe, stick a small sewing needle into the sun's place in the ecliptic, perpendicular to that part of the surface of the globe; this done, turn the globe on its axis, until the needle comes to the Brazen meridian, and set the hour-index to XII at noon; then turn the globe on its axis, until the needle points exactly towards the sun, and the index will shew the hour.

DIRECTIONS FOR USING THE CELESTIAL GLOBE.

The celestial globe is of admirable use for exhibiting the celestial properties of places: we shall therefore now proceed to the use of this globe, premising, that as the equator, ecliptic, tropics, polar circles, horizon, and brazen meridian, are exactly alike on both globes, all the former problems concerning the sun are solved in the same way. The method also of rectifying the globe is the same. N. B. The sun's place for any day of the year stands directly over that day on the horizon of the celestial globe, as on the terrestrial. The latitude and longitude of the stars, and of all other celestial phenomena, are reckoned differently from that of places on the earth: for all terrestrial latitudes are reckoned from the equator; and longitudes from the meridian of some remarkable place; but all astronomers reckon the latitudes of the heavenly bodies from the ecliptic; and their longitudes from the equinoctial colure, in that semicircle of it which cuts the ecliptic at the beginning of Aries; and thence eastward, quite round; so that stars between the equinoctial and the northern half of the ecliptic, have north declination and south latitude; those, between the equinoctial and the southern half of the ecliptic have south declination and north latitude; and all between the tropics and poles, have declinations and latitudes of the same denomination. There are six great circles on the celestial globe, which cut the ecliptic perpendicularly, and meet in two opposite points in the polar circles; which points are each ninety degrees from the ecliptic, and are called its poles. These polar points divide those circles into 12 semicircles; which cut the ecliptic at the beginning of the twelve signs. They resemble so many meridians on the terrestrial globe; and as all places which lie under any particular meridian-semicircle on that globe have the same longitude; so all those points of the heaven, through which any of the above semicircles are drawn, have the same longitude. And as the greatest latitudes on the earth are at the north and south poles of the earth, so the greatest latitudes in the heavens are at the north and south poles of the ecliptic. For the division of the stars into constellations, &c. See ASTRONOMY.

PROB. I. *To find the right ascension and declination of the sun, or any fixed star.*—Bring the sun's place in the ecliptic to the brazen meridian: then that degree in the equinoctial which is cut by the meridian, is the sun's right ascension; and that degree of the meridian which is over the sun's place is his declination. Bring any fixed star to the meridian, and its right ascension will be cut by the meridian in the equinoctial; and the degree of the meridian that stands over it is its declination. So that right ascension and declination, on the celestial globe, are found in the same manner as longitude and latitude on the terrestrial.

PROB. II. *To find the latitude and longitude of any star.*—If the given star be on the north side of the ecliptic, place the 90th degree of the quadrant of altitude on the north pole of the ecliptic, where the 12 semicircles meet, which divide the ecliptic into the 12 signs; but if the star be on the S. side of the ecliptic, place the 90th degree of the quadrant on the south pole of the ecliptic: keep-

ing the 90th degree of the quadrant on the proper pole, turn the quadrant about, until its graduated edge cuts the star: then the number of degrees in the quadrant, between the ecliptic and the star, is its latitude; and the degree of the ecliptic cut by the quadrant, is the star's longitude, reckoned according to the sign in which the quadrant then is.

PROB. III.—*To represent the face of the starry firmament, as seen from any given place of the earth, at any hour of the night.*—Rectify the celestial globe for the given latitude, the zenith, and sun's place in every respect, as taught by the XVIth problem for terrestrial; and turn it about, until the index points to the given hour: then the upper hemisphere of the globe will represent the visible half of the heaven for that time; all the stars upon the globe being then in such situations as exactly correspond to those in the heaven. And if the globe be placed duly north and south, every star in the globe will point toward the like star in the heaven: by which means the constellations and remarkable stars may be easily known; all those stars under the upper part of the brazen meridian, between the south point of the horizon and the north pole, are at their greatest altitude, if the latitude of the place be N. but if the latitude be S. those stars which lie under the upper part of the meridian, between the north point of the horizon and the south pole, are at their greatest altitude.

PROB. IV.—*The latitude of the place, and day of the month, being given; to find the time when any known star will rise, or be upon the meridian, or set.*—Having rectified the globe, turn it about until the given star comes to the eastern side of the horizon, and the index will shew the time of the star's rising; then turn the globe westward, and when the star comes to the brazen meridian, the index will shew the time of the star's coming to the meridian of your place; lastly, turn on, until the star comes to the western side of the horizon, and the index will shew the time of the star's setting. N. B. In northern latitudes, those stars which are less distant from the north pole than the quantity of its elevation above the north point of the horizon never set; and those which are less distant from the south pole than the number of degrees by which it is depressed below the horizon never rise: and vice versa in southern latitudes.

PROB. V.—*To find at what time of the year a given star will be upon the meridian at a given hour of the night.*—Bring the given star to the upper semicircle of the brass meridian, and set the index to the given hour; then turn the globe, until the index points to XII at noon, and the upper semicircle of the meridian will then cut the sun's place, answering to the day of the year sought; which day may be easily found against the like place of the sun among the signs on the wooden horizon.

PROB. VI.—*The latitude, day of the month, and azimuth of any known star, being given; to find the hour of the night.*—Having rectified the globe for the latitude, zenith, and sun's place, lay the quadrant of altitude to the given degree of azimuth in the horizon: then turn the globe on its axis, until the star comes to the graduated edge of the quadrant; and when it does, the index will point out the hour of the night.

PROB. VII.—*The latitude of the place, the day of the month, and altitude of any known star, being given; to find the hour of the night.*—Rectify the globe as in the former problem, guess at the hour of the night, and turn the globe until the index points at the supposed hour; then lay the graduated edge of the quadrant of altitude over the known star; and if the degree of the star's height in the quadrant upon the globe answers exactly to the degree of the star's observed altitude in the heaven, you have guessed exactly; but if the star on the globe is higher or lower than it was observed to be in the heaven, turn the globe backwards or forwards, keeping the edge of the quadrant upon the star, until its centre comes to the observed altitude in the quadrant; and then the index will shew the true time of the night.

PROB. VIII.—*An easy method for finding the hour of the night by any two known stars, without knowing either their altitude or azimuth; and then of finding both their altitude and azimuth, and thereby the true meridian.*—Tie one end of a thread to a common musket-bullet; and having rectified the globe as above, hold the other end of the thread in your hand, and carry it slowly round betwixt your eye and the starry heaven, until you find it cuts any two known stars at once. Then guessing at the hour of the night, turn the globe until the index points to that time in the hour-circle; which done, lay the graduated edge of the quadrant over any one

of these two stars on the globe which the thread cuts in the heaven. If the said edge of the quadrant cuts the other star also, you have guessed the time exactly; but if it does not, turn the globe slowly backwards or forwards, until the quadrant (kept upon either star) cuts them both through their centres: and then the index will point out the exact time of the night; the degree of the horizon cut by the quadrant will be the true azimuth of both these stars from the south; and the stars themselves will cut their true altitudes in the quadrant. At which moment, if a common azimuth-compass be so set upon a floor or level pavement, that these stars in heaven may have the same bearing upon it (allowing for the variation of the needle) as the quadrant of altitude has in the wooden horizon of the globe, a thread extended over the north and south points of that compass will be directly in the plane of the meridian; and if a line be drawn upon the floor or pavement, along the course of the thread, and an upright wire be placed in the southmost end of the line, the shadow of the wire will fall upon that line, when the sun is on the meridian, and shines upon the pavement.

PROB. IX.—*To find the place of the moon, or of any planet; and thereby to shew the time of its rising, southing, and setting.*—Seek in an almanack or ephemeris the geocentric place of the moon or planet in the ecliptic, for the given day of the month; and according to its longitude and latitude, as shewn by the ephemeris, mark the same with chalk upon the globe. Then, having rectified the globe, turn it round its axis westward; and as the said mark comes to the eastern side of the horizon, to the brazen meridian, and to the western side of the horizon, the index will shew at what time the planet rises, comes to the meridian, and sets, in the same manner as it would do for a fixed star.

The most esteemed globes are those of Mr. Jones, mathematical instrument-maker, Holborn, who mounts them so as to retain the principal improvements which have been made by the different authors, who have applied to this subject.

Most of the above problems may also be performed by accurate maps; but this requires a great deal of calculation, which is often very troublesome. The Analemma, or Orthographic Projection, delineated on Plate LXXXI, fig. 3, will solve many of the most curious; and with the assistance of the maps will be almost equivalent to a terrestrial globe. The parallel lines drawn on this figure represent the degrees of the sun's declination from the equator, whether N. or S. amounting to $23\frac{1}{2}$ nearly. On these lines are marked the months and days which correspond to such declinations. The size of the figure does not admit of having every day of the year inserted; but by making allowance for the intermediate days, in proportion to the rest, the declination may be guessed at with tolerable exactness. The elliptical lines are designed to shew the hours of sun-rising or sun-setting, before or after six o'clock. As 60 minutes make an hour of time, a fourth part of the space between each of the hour-lines will represent 15 minutes; which the eye can readily guess at, and which is as great exactness as can be expected from any mechanical invention, or as is necessary to answer any common purpose. The circles drawn round the centre at the distance of $11\frac{1}{4}$ each, shew the point of the compass on which the sun rises and sets, and on what point the twilight begins and ends. To make use of this analemma, it is only necessary to consider, that, when the latitude of the place and the sun's declination are both north or both south, the sun rises before six o'clock, between the east and the elevated pole; that is, towards the north, if the latitude and declination are north; or towards the south, if the latitude and declination are south. Let us now suppose it is required to find the time of the sun's rising and setting, the length of the days and nights, the time when the twilight begins and ends, and what point of the horizon the sun rises and sets on, for the Lizard point in England, Frankfort in Germany, or Abbeville in France, on the 30th of April. The latitude of these places by the maps will be found nearly 50° north. Place a scale or moveable index from the centre, so that its point may touch 50° on the quadrant of north latitude in the figure; then observe where its edge cuts the parallel line on which April 30th is wrote. From this reckon the hour-lines towards the centre, and you will find that the parallel line is cut by the index nearly at the distance of one hour and 15 minutes. So the sun rises at one hour 15 minutes before six, or 45 minutes after four in the morning, and sets 15 minutes after seven in the evening. The length of the day is 14 hours 30 minutes. Observe how far the intersections of the edge of the index with the parallel of April 30th.

30th is distant from any of the concentric circles; which you will find to be a little beyond that marked two points of the compass; and this shews, that on the 30th of April the sun rises two points and somewhat more from the east towards the north, or a little to the northward of E. N. E. and sets a little to the northward of W. N. W. To find the beginning and ending of twilight, take from the graduated arch of the circle 18 degrees with a pair of compasses; move one foot of the compasses extended to this distance along the parallel for the 30th of April, till the other just touches the edge of the index, which must still point at 50. The place where the other foot rests on the parallel of April 30th then denotes the number of hours before six at which the twilight be-

gins. This is somewhat more than three hours and an half; which shews, that the twilight then begins soon after two in the morning, and likewise that it begins to appear near five points from the east towards the north. The uses of this analemma may be varied in a great number of ways; but the example just now given will be sufficient for the ingenious reader. The small circles on the same plate, marked Island, Promontory, &c. are added, to render the maps more intelligible, by shewing how the different subjects are commonly delineated on them. If an analemma of this kind be accurately drawn from a large scale, it will be found very useful and instructive.

GEOLOGY.

GEOLOGY, [*γῆ* and *λογος*,] the science which treats on the formation and structure of the earth. This science is crowded with difficulties; the locality of our situation, the short period allotted us for investigations, the very small depth, to which we can penetrate below the earth's surface, and the contracted extent of excavations which can be made by art, render our knowledge of the formation and structure of the earth, very deficient and contracted. Hence have arisen widely varying theories of the earth, some of which, though framed by philosophers, are more wild and fanciful than the visionary scenes of the poets. However we find some rational intelligence in the "Elements of Geognosy," by Professor Jameson, who places in a beautiful view the system of the celebrated Werner. We shall select a few observations from this treatise, and refer to the work itself for fuller information. "When we examine the surface of the globe particularly, a certain locality of its inequalities is to be observed. Thus the most considerable inequalities, those, namely, which present the most frequent and the deepest sections and fissures, are always found in the more elevated regions; while in the lower places, we observe very few, and by no means special elevations and depressions. We further observe, that the masses of which the higher and lower parts of the earth are composed, are by no means of the same nature; elevated, rugged, and very uneven places, are mostly composed of rocky masses, which present to the eye rough, bare, fissured cliffs, mural precipices, and even entire rocky valleys. On the other hand, in the lower parts of the earth, we find in general earthy masses, as clay, loam, sand, and rolled stones; but neither cliffs, nor rocky valleys; and only single blocks of the materials of the more elevated places. The rocks of which the elevated parts of the earth are composed, are also different, according to their local situation. Thus the most elevated parts are principally composed of fossils belonging to the flint, clay, and talc genera, as quartz, felspar, mica, and chlorite, and these are usually crystallized. The elevations, which are somewhat lower, or those of middle height, are composed of clayey fossils. The calcareous genus here makes its appearance in considerable quantity, and increases very much; so that at length, in the form of gypsum and limestone, it forms the prevalent substance in the lower rocky places. Even in still lower places, we meet with formations of flinty fossils, derived from rocks that compose the higher parts of the globe, as sand-stone. The sand and gravel which occur in still lower situations, are nearly allied to the last-mentioned rocks. There is still another general and very interesting observation to be made, namely, that the remains of organic beings, more or less changed (what are denominated petrifications,) are found imbedded in these rocks. These remarkable bodies are generally found in the middle and lower heights of the earth. In the middle heights they are still very rare; but they increase in variety and number as we approach the lower places, and are at length accumulated in immense quantities in the lowest parts. We also observe that the organic remains found in the middle heights are totally changed

into stone, but the more we descend into the lower places, the more these bodies appear unaltered, or approach to their original state. It is also observed, that the higher places afford different genera and species of petrifications from those found in the lower; and although we are able to shew the originals of many of those bodies, which are found in the lower places, as proofs of their origin, there occur in the middle heights some whose originals we are ignorant of. Lastly, we may remark, that in all the situations already mentioned, that is, from the middle to the lowest height, but particularly in the latter, there are some rocks, in which few or no traces of such bodies have ever been found; although from the local situation of the rocks, we might readily expect to find petrifications in them, as in other rocks of the same relative height. When we examine the surface of the earth more particularly, we find that the special inequalities are included in others more general; that these general inequalities are again contained in others still more general; and that at length the whole are included in the most general. Those inequalities may be divided into five classes or degrees. The first contains the most general inequalities; these are the bottom of the sea and the dry land. The second comprehends what may be termed low country, and high country. The third, which is more special, comprehends mountain-groups. The fourth, which is still more particular, comprehends mountain-chains and valleys. The fifth and last, which is most special, comprehends single mountains, and the ravines or valleys between them. We have thus a most beautiful series from the single mountain and the ravine, to the great fabric of the high country, and still further to the most general division of the inequalities of the earth's surface, the dry land and the bottom of the sea." According to the system of Werner, the earth is supposed to have existed originally in a fluid state, which appears to be evinced from the figure of the earth, and from the substances composing the different rocks and mountains, as well as from their formations. From a very attentive consideration, and close investigation of this subject, which is evidenced every where in his work, he has determined the order of the different formations as follows:

I. CLASS. Primitive Rocks. By the earliest separations from the chaotic mass, which are discovered in the crust of the globe, was formed a class of rocks, which are therefore termed primitive rocks, being chiefly composed of silex, alumina, and magnesia, constituting by their various intermixtures, 1. granite; 2. gneiss; 3. mica-slate; 4. clay-slate; 5. primitive lime-stone; 6. primitive trap; 7. serpentine; 8. porphyry; 9. sienite; 10. topaz-rock; 11. quartz-rock; 12. primitive flinty-slate; 13. primitive gypsum; 14. white-stone. The circumstances which chiefly mark the high antiquity of these rocks are, that they form the fundamental rock of the other classes; and that the outgoings of their strata are generally higher than those of the other classes. Having been formed in the uninhabitable state of the globe, they contain no petrifications; and, excepting the small portion which sometimes accom-

GEOGRAPHY.

An Analemma, shewing the time of Sun rising and sun setting, the length of the Days and Nights, & the point of the Compass on which the Sun rises and sets, for every Degree of Latitude & for every Degree of the Sun's North & S. Declination.

company those which will be next mentioned, they contain no mechanical deposits, but are throughout pure chemical productions. Small portions of carbonaceous matter occur only in the newer members of the class.

II. CLASS. *Transition Rocks.* On the appearance of land, or during the transition of the earth from its chaotic to its habitable state, rocks which, from this circumstance, are denominated transition-rocks, were formed. In these rocks the first slight traces of petrifications, and of mechanical depositions, are to be found. The species of rocks which come under this class are the transition lime-stone, transition-trap, grey-wacke, and flinty-slate. The petrifications are corallites, encrinites, pentacrinites, entrochites, and trochites. The lime-stone of Derbyshire is said to be of this kind. As the former class of rocks were purely of chemical formation, so the contents of these are chiefly chemical productions, mingled with a small proportion of mechanical depositions. To explain the cause of this mixture, we are referred to the period of their formation, that at which the summits of the primitive mountains just appeared above the waters, when, by the attrition excited by the motion of the waves, and which we are reminded extends to no great depth, particles of the original mountains were worn off and deposited.

III. CLASS. *Flatz Rocks.* As the height of the level of the ocean diminished, so would the surface on which its waves acted increase, and of course the quantity of the mechanical depositions. Hence these are much more abundant in the rocks of the next formation, which are denominated flatz rocks, on account of their being generally disposed in horizontal or flat strata. In these, petrifications are very abundantly found, having been formed whilst vegetables and animals existed in great numbers. These rocks are generally of very wide extent, and commonly placed at the feet of primitive mountains. They are seldom of very great height, from whence it may be inferred, that the water had considerably subsided at the time of their formation, and did not then cover the whole face of the earth. Countries composed of these rocks are not so rugged in their appearance, nor so marked by rapid inequalities, as those in which the primitive and transition-rocks prevail. The formations of this class are supposed to be, 1. first or old red sand-stone; 2. first or oldest flatz lime-stone; 3. first or oldest flatz gypsum; 4. second or variegated sand-stone; 5. second flatz gypsum; 6. second flatz or shell lime-stone; 7. third flatz sand-stone; 8. Rock-salt formation; 9. chalk-formation; 10. flatz-trap formation; 11. independent coal-formation; 12. newest flatz-trap formation. Most of the rocks which have been just enumerated are covered by the formations

which is named the newest flatz trap. This formation also covers many of the high primitive mountains: it has but little continuity, but is very widely distributed. It contains considerable quantities of mechanical deposits, such as clay, sand, and gravel. The remains both of vegetables and animals also occur very abundantly in these deposits. Heaps of trees and of parts of plants, and an abundance of shells and other marine productions, with the horns of stags, and great beds of bituminous fossils, point out the lateness of the period when this formation was deposited. In this formation several rocks occur which are also met with in other flatz-formations; but the following are supposed to be peculiar to this class, basalt, wacke, grey-stone, porphyry slate and trap tuff. These rocks are said to have been formed during the settling of the water consequent to a vast deluge, which is supposed to have taken place when the surface of the earth was covered with animals and vegetables, and when much dry land existed. From various appearances observed in these rocks it is concluded, that the waters, in which they were formed, had risen with great rapidity, and had afterwards settled into a state of considerable calmness.

IV. CLASS. *Alluvial Rocks.* The collections and deposits derived from the materials of pre-existing masses, worn down by the powerful agency of air and water, and afterwards deposited on the land or on the sea-coasts, are termed alluvial, and are, of course, of much later formation than any of the preceding classes. These deposits may be divided into, 1. Those which are formed in mountainous countries, and are found in vallies, being composed of rolled masses, gravel, sand, and sometimes loam, fragments of ores, and different kinds of precious stones. 2. Those which occur in low and flat countries, being peat, sand, loam, bog iron-ore, nagelflech, calc-tuff and calc-sinter: the three latter being better known by the names breccia, tufa, and stalactite.

V. CLASS. *Volcanic Rocks.* The abovementioned formations are called *aquatic*, as being effected principally in aqueous solutions, or by the agency of water. This class is termed igneous, because it is effected by means of fire, and is the last in the arrangement because of its newness. In this class are these substances, viz. 1. burnt-clay; 2. porcelain-jasper; 3. earth-slug; 4. columnar clay-iron stone; 5. polishing slate; 6. ejected stones, and ashes; 7. different kinds of lava; 8. the matter of muddy eruptions. The five first are called pseudo-volcanic rocks; the three last, true volcanic rocks. The reader who wishes to pursue this subject, will find much profit and pleasure in the perusal of Professor Jameson's Treatise on Geognosy which we have already noticed.

GEOMANCY, or GEOMANTIA, is performed by means of a number of little points, or dots, made on paper at random; and by forming from the various lines and figures which those points present, a pretended judgment of futurity, upon any question proposed. The word is derived from the Greek, *γῆα*, earth, and *μαντεία*, divination; it being the ancient custom to cast little pebbles on the earth, and thence to form their conjectures, instead of the points afterwards made use of.

GEOMETRICAL CONSTRUCTION, or CONSTRUCTION OF EQUATIONS. See ALGEBRA and EQUATION.

GEOMETRICAL CURVES. See ALGEBRA and CURVES.

GEOMETRICAL LINE. See LOCUS.

GEOMETRICAL PACE, a measure five feet long.

GEOMETRICAL PROGRESSION, a progression in which the terms have all successively the same ratio; as, 1, 2, 4, 8, 16, &c. where the common ratio is 2. See ALGEBRA.

GEOMETRICAL PROPORTION is the similitude or equality of ratios, called also simply Proportion. See GEOMETRY.

GEOMETRICAL SERIES. See ALGEBRA.

GEOMETRICAL SOLUTION is when a problem is resolved according to the strict rules of geometry, and by lines truly geometrical. This expression is used in contradistinction to an arithmetical, instrumental, or mechanical solution.

GEOMETRICUS LOCUS. See LOCUS.

GEOMETRY.

GEOMETRY, [*γῆα*, the earth, and *μετρεω*, to measure,] originally signified the art of measuring the earth, or any distances or dimensions on or within it; but it is now used for the science of quantity, extension, or magnitude, abstractedly considered, with-

out any regard to matter. Geometry, together with arithmetic, now forms the chief foundation of all the mathematics.

HISTORY.

The invention of geometry is generally ascribed to the Egyptians.

tians. Herodotus, Diodorus, Strabo, and Proclus, all agree that the annual inundations of the Nile gave rise to it, by carrying away the land-marks and boundaries of estates and farms; and covering the surface of the ground with mud, which effaced every trace of their former limits. Hence the Egyptians were obliged every year to distinguish and lay out their lands by the consideration of their figure and quantity, that every person might have his own property: and thus, by repeated experience and practice, in drawing figures, lines, and schemes, for this purpose, they gradually formed an art which, from its origin, in the measuring of lands, the Greeks at last named *Γεωμετρία*, Geometry, from *γη* or *γῆ*, the land or earth, and *μετρον*, a measure, from *μετρον* to measure; hence the Romans called this science *geometria*, the French *geometrie*, &c. By farther contemplation of the draughts of figures, their wonderful properties were more and more discovered, and the art continually gained ground and improved, by the discoveries of succeeding mathematicians. This appears to be the most probable origin of this science; though Josephus seems to ascribe the invention to the Hebrews; while others of the ancients make Mercury the inventor. Polyd. Virg. de Inv. Rer. l. 1. c. 18. Thales is said to have introduced this science from Egypt into Greece; where it was greatly cultivated and improved by himself, as well as by Pythagoras, Anaxagoras of Clazomene, Hippocrates of Chios, and Plato; who testified his conviction of the necessity and importance of Geometry to the successful study of Philosophy, by inscribing over the door of his Academy, "Let no one ignorant of Geometry enter here." Plato thought the word Geometry too mean a name for this science; and substituted instead of it the more extensive name of Mensuration; and after him others gave it the title of Pantometry. But even these are now become too confined in their import, fully to comprehend its extent; for it not only inquires into, and demonstrates the quantities of magnitudes, but also their qualities, as the species, figures, ratios, positions, transformations, descriptions, divisions, the finding of their centres, diameters, tangents, asymptotes, curvatures, &c. About 50 years after Plato, Euclid collected together all those theorems, which had been invented by his predecessors in Egypt and Greece, and digested them into 15 books, entitled "The Elements of Geometry;" demonstrating and arranging the whole in a very accurate and perfect manner. The next to Euclid, of those ancient authors whose works are extant, is Apollonius Pergæus, who flourished in the reign of Ptolemy Euergetes, about B. C. 230, and 100 years after Euclid. He was author of the first and principal work on Conic Sections; on account of which, and his other accurate and ingenious geometrical works, he acquired from his patron the emphatical appellation of the Great Geometrician. The contemporary with Apollonius, or perhaps a few years, before him, flourished Archimedes, celebrated for his extraordinary mechanical inventions during the siege of Syracuse, and no less so for his many ingenious geometrical compositions. Eudoxus of Cnidus, Archytas of Tarentum, Philolaus, Eratosthenes, Aristarchus of Samos, Dinostratus, the inventor of the quadratrix, Menæchmus his brother, and the disciple of Plato, the two Aristeuses, Conon, Thracidius, Nicoteles, Leon, Theudius, Hermotimus, Hero, and Nicomedes, the inventor of the conchoid; besides many other ancient geometricians, have contributed to the improvement of geometry. The Greeks continued their attention to it, even after they were subdued by the Romans; whereas the Romans themselves were so little acquainted with it, even in the most flourishing time of their republic, that Tacitus informs us they gave the name of mathematicians to those who pursued the chimeras of divination and judicial astrology. Nor does it appear they were disposed to cultivate geometry during the decline, and after the fall of the Roman empire. But the case was different with the Greeks; among whom are found many excellent geometricians since the commencement of the Christian era, and after the translation of the Roman empire. Ptolemy lived under Marcus Aurelius; and we have still extant the works of Pappus of Alexandria, who lived in the time of Theodosius; the commentary of Eutocius, the Ascalonite, who lived about A. D. 540, on Archimedes's mensuration of the circle; and the commentary on Euclid, by Proclus, who lived under the empire of Anastasius. The consequent inundation of ignorance and barbarism was unfavourable to geometry, as well as to the other sciences; and the few who applied themselves to this science, were calumniated as magicians. However, in those times of European darkness, the

Arabians were distinguished as the guardians and promoters of science; and from the 9th to the 14th century, they produced many astronomers, geometricians, geographers, &c.; from whom the mathematical sciences were again received into Spain, Italy, and the rest of Europe, somewhat before the year 1400. Some of the earliest writers after this period, are Leonardus Pisanus, Lucas Pacciolus or De Burgo, and others between 1400 and 1500. And after this appeared many editions of Euclid, or commentaries upon him: thus, Orontius Finæus, in 1530, published a commentary on the first six books; as did James Peletarius, in 1556; and about the same time Nicholas Tartaglia published a commentary on the whole 15 books. There have been also the editions, or commentaries, of Commandine, Clavius, Billingsly, Scheubelius, Herlinus, Dasypodius, Ramus, Herigon, Stevinus, Saville, Barrow, Tacquet, Dechales, Fournier, Scarborough, Keill, Stone, and many others; but the completest edition of all the works of Euclid, is that of Dr. Gregory, printed at Oxford in 1703, in Greek and Latin. The edition of Euclid, by Dr. Robert Simson of Glasgow, containing the first six books, with the 11th and 12th, is much esteemed for its correctness. The principal other elementary writers, besides the editors of Euclid, are Pardies, Marchetti, Wolfius, Simpson, &c. And among those who have gone beyond Euclid in the nature of the elementary parts of geometry, may be chiefly reckoned, Apollonius, in his *Cônes*, his *Loci Plani*, *De Sectione Determinata*, his *Tangencies*, *Inclinations*, *Section of a Ratio*, *Section of a Space*, &c.; Archimedes, in his treatises of the *Sphere* and *Cylinder*, the *Dimension of the Circle*, of *Conoids* and *Spheroids*, of *Spirals*, and the *quadrature of the Parabola*: Theodosius, in his *Spherics*, Serenius, in his *Sections of the Cone and Cylinder*; Kepler's *Nova Stereometria*; Cavalieri's *Geometria Indivisibilium*; Torricelli's *Opera Geometrica*; Viviani in his *Divinationes Geometricæ*, *Exercitatio Mathematica*, *De Locis Solidis*, *De Maximis et Minimis*, &c.; Vieta, in his *Effectio Geometrica*, Supplement. *Geometria*, *Sectiones Angulares*, *Responsum ad Problema*, Apollonius Gallus, &c.; Gregory St. Vincent's *Quadratura Circuli*; Fermat's *Varia Opera Mathematica*; Dr. Barrow's *Lectiones Geometricæ*; Bulliald de *Lineis Spiralibus*; Cavalieri; Schooten and Gregory's *Exercitationes Geometricæ*, and Gregory's *Pars Universalis*, &c.; De Billy's treatise *De Proportionibus Harmonicis*; La Douera's *Geometria Veterum promota*; Slusius *Mesolabium*, *Problemata Solida*, &c.; Wallis in his treatises *De Cycloide*, *Cissoide*, &c.; *De Proportionibus*, *De Sectionibus*, *Conicis*, *Arithmetica Infinitorum*, *De Centro Gravitatis*, *De Sectionibus Angularibus*, *De Angulo Contactus*, *Cuno Cuneus*, &c. &c.; Hugo De Omerique, in his *Analysis Geometrica*; Pascal on the *Cycloid*; Steph. Angeli's *Problemata Geometrica*; Alex. Anderson's *Suppl. Redivivi*, *Variorum Problemata Practica*, &c.; Baroni's *Geomet. Prob.* &c.; Guido Grandini *Geometr. Demonstr.* &c.; Ghetaldi Apollonius *Redivivus*, &c.; Ludolph van Colen or a Ceulen, de *Circulo et Adscriptis*, &c.; Snell's Apollonius *Batavus*, *Cyclometricus*, &c.; Heberstein's *Diotomo Circulorum*; Palma's *Exercit. in Geometriam*; Guldini *Centro Baryca*; with several others equally eminent, of more modern date, as Dr. Rob. Simson, Dr. Mat. Stewart, Mr. Tho. Simpson, &c. Since the introduction of the new geometry, or the geometry of curve lines, as expressed by algebraical equations, in this part of geometry, the following names, among many other, are more especially to be respected, viz. Des Cartes, Schooten, Newton, Maclaurin, Brackenridge, Cramer, Cotes, Waring, &c. &c. As to the subject of practical geometry, the chief writers are Beyer, Kepler, Ramus, Clavius Mallet, Tacquet, Ozanami, Wolfius, Gregory, with innumerable others. On the whole, the history of geometry may be divided into four grand eras; viz. 1. From its invention to its introduction into Greece by Thales: 2. From that period to its meridian-glory under Euclid; 3. From Euclid and Archimedes to Descartes, who, by applying algebra to the elements of geometry, gave a new turn to this science: and, 4. From Descartes to its perfection by Sir Isaac Newton and M. Leibnitz, who introduced still greater improvements by the application of Fluxions. This science is generally divided into two parts: viz. I. Theoretical Geometry, containing the general principles of the science: and, II. Practical Geometry, or the application of these principles to the mensuration of surfaces, solids, &c. We shall in the sequel of this article treat of these two grand branches of Geography in the order just laid down.

PART I.

THEORETICAL GEOMETRY;

OR, GENERAL PRINCIPLES OF THE SCIENCE.

Of STRAIGHT LINES and PLANE FIGURES.

DEFINITIONS.

1. A POINT is that which has position, but not magnitude.
2. A LINE is length without breadth or thickness; the extremities of a line are therefore points.
3. A RIGHT LINE, or STRAIGHT LINE, is that which lies evenly between its extreme points. Fig. 1. Plate LXXXII. and LXXXIII.
4. A SUPERFICIES is that which has only length and breadth; the extremities of a superficies are therefore lines, and the intersections of superficies with one another are also lines.
5. A PLANE SUPERFICIES is that in which any two points being taken, the straight line between them lies wholly in that superficies.
6. A PLANE RECTILINEAL ANGLE is the inclination of two straight lines to one another, which meet together, but are not in the same straight line. Fig. 2.
- Note. When several angles are formed at the same point, as at B, fig. 3, each particular angle is described by three letters, whereof the middle one shews the angular point, and the other two the lines that form the angle thus, CBD, or DBC, denotes the angle contained by the lines CB and DB.
7. When a straight line standing on another straight line makes the adjacent angles equal to one another, each of the angles is called a RIGHT ANGLE, and the straight line which stands on the other is called a PERPENDICULAR. Fig. 4.
8. An OBTUSE ANGLE is that which is greater than a right angle. Fig. 5.
9. An ACUTE ANGLE is that which is less than a right angle. Fig. 6.
10. PARALLEL STRAIGHT LINES are such as are in the same plane, and which being produced ever so far both ways do not meet. Fig. 7.
11. A FIGURE is that which is enclosed by one or more boundaries.
12. RECTILINEAL FIGURES are those which are contained by straight lines.
13. Every plane figure bounded by three straight lines is called a TRIANGLE, of which the three straight lines are called the SIDES, that side upon which the triangle is conceived to stand is called the BASE, and the opposite angular point the VERTEX.
14. An EQUILATERAL TRIANGLE is that which has three equal sides. Fig. 8.
15. An ISOSCELES TRIANGLE is that which has only two equal sides. Fig. 9.
16. A SCALENE TRIANGLE is that which has all its sides unequal. Fig. 11.
17. A RIGHT-ANGLED TRIANGLE is that which has a right angle. Fig. 10.
18. An OBTUSE-ANGLED TRIANGLE is that which has an obtuse angle. Fig. 11.
19. An ACUTE-ANGLED TRIANGLE is that which has all its angles acute. Fig. 12.
20. Every plane figure bounded by four straight lines is called a QUADRILATERAL, and the right line joining the opposite angles is called a DIAGONAL.
21. A PARALLELOGRAM is a quadrilateral of which the opposite sides are parallel. Fig. 13.
22. A RECTANGLE is a parallelogram which has all its angles right angles. Fig. 14.
23. A SQUARE is a parallelogram which has all its sides equal, and all its angles right. Fig. 15.
24. A RHOMBUS is a parallelogram which has all its sides equal. Fig. 17.
25. A TRAPEZIUM is a quadrilateral which has not its opposite sides parallel. Fig. 18.
26. A TRAPEZOID is a quadrilateral which has two of its opposite sides parallel. Fig. 19.
27. Plane figures bounded by more than four straight lines are called POLYGONS. Fig. 16.
28. A PENTAGON is a polygon of five sides; a HEXAGON hath

six sides; a HEPTAGON seven; an OCTAGON eight; a NONAGON nine; a DECAGON ten; an UNDECAGON eleven; and a DODECAGON hath twelve sides.

29. A REGULAR POLYGON hath all its sides, and all its angles, equal; if they be not equal, the polygon is IRREGULAR.

30. A CIRCLE is a plane figure bounded by one line called the circumference, which is such that all straight lines drawn to it from a certain point within it called the centre are equal; and these straight lines are called the RADII of the circle. The circumference itself is also often called a circle. Fig. 20.

31. The DIAMETER of a circle is a straight line passing through the centre, and terminated both ways by the circumference, as AB. Fig. 20.

32. An ARC of a circle is any part of its circumference, as ABC. Fig. 21.

33. A CHORD is a straight line joining the extremities of an arc, as AC. Fig. 21.

34. A SEGMENT is any part of a circle bounded by an arc and its chord, as ABCA. Fig. 21.

35. A SEMICIRCLE is half the circle, or a segment cut off by a diameter. The half-circumference is also sometimes called a semicircle. Fig. 20.

36. A SECTOR is any part of a circle which is bounded by an arc, and two radii drawn to its circumference, as ABC. Fig. 22.

37. A QUADRANT, or quarter of a circle, is a sector having a quarter of a circle for its arc, and its two radii are perpendicular to each other. A quarter of the circumference is also called a quadrant, as ABC. Fig. 23.

38. The HEIGHT or ALTITUDE of a figure is a perpendicular let fall from an angle or its vertex to the opposite side or base, as FE. Fig. 24.

39. In a right-angled triangle the side opposite the right angle is called the HYPOTHENUSE, and the other two sides are called the LEGS, or sides, or sometimes the base and perpendicular. Fig. 10.

40. The circumference of every circle is supposed to be divided into 360 equal parts called DEGREES, and each degree into 60 MINUTES, each minute into 60 SECONDS, and so on. Hence a semicircle contains 180 degrees, and a quadrant 90 degrees.

41. The MEASURE of a RECTILINEAL ANGLE is an arc of any circle contained between the two lines which form that angle, the angular point being the centre, and it is estimated by the number of degrees in that arc. Fig. 25.

42. The IDENTICAL FIGURES are such as have all the sides and all the angles of the one, respectively equal to all the sides and all the angles of the other, each to each, so that if the one figure were applied to, or laid upon the other, all the sides of the one would exactly fall upon and cover all the sides of the other, the two becoming as it were but one and the same figure.

43. The DISTANCE of a POINT from a LINE is the straight line drawn from that point perpendicular to, and terminating in, that line.

44. An ANGLE in a SEGMENT of a CIRCLE is that which is contained by two lines drawn from any point in the arc of the segment to the extremities of that arc, as ABC in the segment ABC. Fig. 26.

45. An ANGLE on a SEGMENT, or an ARC, is that which is contained by two lines drawn from any point in the opposite, or supplemental part of the circumference, to the extremities of the arc, and containing the arc between them, as ABC on the segment ADC. Fig. 26.

46. An ANGLE at the CIRCUMFERENCE is that whose angular point is any where in the circumference, and an angle at the centre is that whose angular point is at the centre.

47. A TANGENT to a CIRCLE is a straight line that meets the circumference at one point, and every where else falls without it. Fig. 27.

48. A SECANT is a straight line that cuts the circle, lying partly within and partly without it. Fig. 27.

49. A RIGHT-LINED FIGURE is inscribed in a circle, or the circle circumscribes it when all the angular points of the figure are in the circumference of the circle. Fig. 28.

50. A RIGHT-LINED FIGURE circumscribes a circle, or the circle is inscribed in it when all the sides of the figure touch the circumference of the circle. Fig. 28.

51. ONE RIGHT LINE A FIGURE is inscribed in another, or the latter

latter circumscribes the former when all the angular points of the former are placed in the sides of the latter. Fig. 29.

52. **SIMILAR FIGURES** are those that have all the angles of the one equal to all the angles of the other, each to each, and the sides about these angles proportional.

The **PERIMETER** of a **FIGURE** is the sum of all its sides taken together.

Note. When the word **line** occurs, without the addition of either *straight* or *curved*, a straight line is always meant; also the contractions (Def.) (Ax.) (Th.) are references to the definitions, axioms, and theorems, that have been before mentioned.

AXIOMS.

1. Things which are equal to the same thing are equal to one another.
2. When equals are added to equals, the wholes are equal.
3. When equals are taken from equals, the remainders are equal.
4. When equals are added to unequals, the wholes are unequal.
5. When equals are taken from unequals, the remainders are unequal.
6. Things which are doubles of the same thing are equal to one another.
7. Things which are halves of the same thing are equal.
8. The whole is equal to all its parts taken together.
9. Things which coincide, or fill the same space, are identical, or mutually equal in all their parts.
10. All right angles are equal to one another.
11. Angles that have equal measures, or arcs, are equal.
12. More than one straight line cannot be drawn from any given point to another given point. Fig. 1.
13. If two straight lines meet one another, they are not both parallel to one and the same straight line. Thus CD and CE are not both parallel to AB . Fig. 29.

REMARKS. A **PROPOSITION** is something proposed to be done, and is either a **Problem** or **Theorem**.

A **PROBLEM** is something proposed to be done.

A **THEOREM** is something proposed to be demonstrated.

A **LEMMA** is something premised or demonstrated, in order to make what follows the more easy.

A **COROLLARY** is a consequent truth gained immediately from some preceding truth or demonstration.

A **SCHOLIUM** is a remark or observation made upon something going before.

THEOREM I. fig. 30. If two triangles have two sides and the included angle of the one equal to two sides and the included angle of the other, the triangles will be identical, or equal in all respects.

In the two triangles ABC , DEF , if the side AB of the one be equal to the side DE of the other, and the side AC equal to DF , also the angle A equal to the angle D , the triangles shall be identical, or equal, in all respects. For conceive the triangle ABC , to be applied to, or placed upon, the triangle DEF ; so that the point A may coincide with D , and the side AB with the side DE ; then since the angles A and D are equal, the side AC shall also coincide with DF ; and since AB is equal to DE , and AC is equal to DF , the points B and E shall coincide, as also the points C and F ; consequently the side BC will coincide with the side EF ; (Ax. 12.) therefore the two triangles are identical (Ax. 9.) and have all their other corresponding parts equal.

THEOREM II. fig. 30. Triangles which have two angles and the side which lies between them equal are identical, or have their other sides and angles equal. Let the two triangles ABC , DEF , have the angle B equal to the angle E , the angle C equal to the angle F , and the side BC equal to the side EF , then these triangles will be identical. For conceive the triangle ABC placed upon DEF , so that BC may fall exactly upon EF , then since the angle B is equal to the angle E , the side BA will fall upon DE , and in like manner because the angles C and F are equal, the side CA will fall upon FD , thus the triangles will exactly coincide, and therefore, (Ax. 9.) are identical.

THEOREM III. fig. 31. In an isosceles triangle the angles at the base are equal. If the triangle ABC be isosceles, or have a side AB equal to a side AC ; then will the angle at B be equal to the angle at C . For conceive the angle at A to be bisected, or di-

vided into two equal parts by the line AD . Then the triangles BAD , CAD , having two sides and a contained angle of the one equal to two sides and the contained angle of the other, namely, AB equal to AC , and AD common to both, and the angle BAD equal to the angle CAD , are equal in all respects (Th. 1.) therefore the angle B is equal to the angle C .

COROLLARY I. An equilateral triangle is also equiangular.

COR. 2. A line that bisects the vertical angle of an isosceles triangle bisects also the base, and is perpendicular to it.

THEOREM IV. fig. 31. If a triangle have two of its angles equal, the sides which subtend or lie opposite to these angles are also equal. Let ABC be a triangle, of which the angles at B and C are equal, the side AB will be equal to the side AC . For conceive the angle A to be bisected by AD ; then the angles BDA and CDA are equal, being right angles (Th. 3. Cor. 2.) and the angles at A are equal, also AD is common; hence the triangles BAD , CAD , are identical, (Th. 2.) and AB is equal to AC .

COR. Hence every equiangular triangle is also equilateral.

THEOREM V. fig. 32. Triangles which have their three sides mutually equal, are identical, or have all their three angles equal, each to each. Let the triangles ABC , ADC , have their three sides mutually equal, viz. AC equal to AC , AB equal to AD , and BC equal to DC , the angles opposite to these sides shall be equal, namely BAC to DAC , BCA to DCA , and ABC to ADC . Suppose the triangles joined by their longest equal sides, and join BD . Then the angle ABD is equal to ADB , and the angle CBD to the angle CDB (Th. 3.) therefore the whole angle ABC is equal to the whole angle ADC , (Ax. 2.) and since AB is equal to AD , also BC to DC , the triangle ABC , ADC , are identical. (Th. 1.)

THEOREM VI. fig. 33. The angles which one line makes with another upon one side of it are together equal to two right angles. Let the line AB make with CD upon one side of it, the angles ABD , ABC ; these are together equal to two right angles. If AB be perpendicular to CD , the angles ABC , ABD , are evidently equal to two right angles (def. 7.) But if AB be not perpendicular to CD , draw BE perpendicular to CD , dividing the greater angle ABC into the two angles EBC , EBA ; then the former EBC being a right angle, and the remaining part EBA together with the whole less angle ABD , is equal to another right angle; the whole of both the proposed angles is therefore equal to two right angles. (Ax. 2.)

COR. 1. Hence also, conversely, if the two angles ABC , ABD , on both sides of the line AB , make up together two right angles, then CB and BD form one continued straight line.

COR. 2. All the angles that can be made round a point by any number of lines are equal to two right angles.

THEOREM VII. fig. 34. If two lines intersect each other, the opposite angles are equal. Let AB and CD intersect each other in E , the angle AEC is equal to BED , and AED to BEC ; for the angles AEC , AED , are together equal to two right angles (Th. 6.) and in like manner BED , AED , are equal to two right angles; therefore the angles AEC , AED , are together equal to BED , AED (Ax. 1.) and taking away the common angle AED from both, there remains AEC equal to BED (Ax. 3.) In like manner it will appear that AED is equal to BEC .

THEOREM VIII. fig. 35. If a line intersecting two other lines, make the alternate angles equal, the lines are parallel. Let EF intersect the lines AB , CD , and make the alternate angles AGH , and GHD , equal, then AB is parallel to CD . For if not they will meet on one side, let them meet in I , and let GH be bisected in K , and IK joined and produced to L , so that KL be equal to IK , and let GL be joined; then because LK is equal to KI , and GK to KH , and the included angles at K equal, being vertical angles, the triangles LKG and IHK are identical (Th. 1.) Therefore the angle LKG is equal to KHD , and therefore (by Hyp.) equal to AGH , which is impossible. Therefore the lines AB , CD , do not meet, consequently they are parallel (def. 10.)

COR. If a line intersecting two other lines make the exterior angle equal to the interior angle on the same side, or the two interior angles on the same side equal to two right angles, these lines are parallel.

THEOREM IX. fig. 36. If a line intersect two parallel lines, it makes the alternate angles equal.

Let the line EF intersect the parallel lines AB , CD , at G and H .

H, the alternate angles AGH, GHD, are equal. For if not, let the angle KGB be equal to GHD, then KG is parallel to CD (Th. 8;) therefore AG and KG are both parallel to CD, which is impossible, (Ax. 13.)

COR. If a line intersect two parallel lines it makes the exterior angle equal to the interior and opposite on the same side, and also the two interior angles on the same side equal to two right angles. For the interior angle GHD is equal to AGH, that is, (Th. 7,) to the exterior angle EGB; to each of these add BGH, and the two interior angles BGH, GHD, are together equal to BGH, BGE, that is, to two right angles. (Th. 6.)

THEOR. X. fig. 37. If one side of a triangle be produced, the exterior angle is equal to both the interior and opposite angles, and the three interior angles are equal to two right angles.

Let BC, a side of the triangle ABC, be produced to D, the exterior angle ACD is equal to the two interior and opposite angles BAC, ABC, and the three interior angles ABC, BAC, BCA, are equal to two right angles. Let CE be parallel to AB, then the angle ACE is equal CAB (Th. 9,) and the angle ABC to ECD, (Th. 9, Cor.) therefore the angle ACD is equal to the two angles CAB, CBA; to each of these equals add ACB, thus the angles ACB, ACD, are equal to the three angles ABC, CBA, BAC, but ACB, ACD, are equal to two right angles (Th. 6,) therefore the three angles of the triangle are equal to two right angles.

COR. 1. The exterior angle of a triangle is greater than either of the interior opposite angles.

COR. 2. Any two angles of a triangle are together less than two right angles.

COR. 3. If two triangles have two angles of the one equal to two angles of the other, the remaining angle of the one is equal to the remaining angle of the other.

COR. 4. The two acute angles of a right-angled triangle are together equal to a right angle.

THEOR. XI. fig. 38. The greatest side of every triangle subtends the greatest angle.

Let ABC be a triangle of which the side AB is greater than AC, the angle ACB is greater than ABC. Take AD equal to AC, and join DC, then the angle ACD is equal to ADC (Th. 3;) but ADC is greater than ABC (Th. 10, Cor. 1,) therefore ACD is greater than ABC, much more then is ACB greater than ABC.

COR. The greatest angle of every triangle is subtended by the greatest side.

THEOR. XII. fig. 39. The opposite sides and opposite angles of a parallelogram are equal, and the diagonal divides the parallelogram into two equal parts.

Let ABC be a parallelogram, AB is equal CD, and AC to BD, also the angle CAB is equal to CDB, and ACD to ADB, and the triangle ACD is equal to ABD. For since AB is parallel to CD (def. 21,) the angles BAD, CDA, are equal (Th. 10,) and since AC is parallel to BD, for the same reason, the angles CAD, BDA, are equal, now AD is common to the triangles ABD, ACD, therefore these triangles are identical, (Th. 2;) hence AB is equal to CD, AC to BD, the angle ACD to ABD, the angle CAD to ADB, and BAD to ADC, and consequently the whole angle CAB to the whole angle CDB.

THEOR. XIII. fig. 39. The lines which join the extremities of equal and parallel lines towards the same parts are themselves equal and parallel.

Let AB be equal and parallel to CD, then AC and BD are also equal and parallel. Join AD, then the angles BAD, CDA, are equal, (Th. 9,) and since AB is equal to CD, and AD common to the triangles ABD, ACD, these triangles are equal in all respects (Th. 1,) therefore AC is equal to BD, and the angle CAD to ADB, hence AC is also parallel to BD. (Th. 8.)

THEOR. XIV. fig. 40. Parallelograms standing upon the same base, and between the same parallels, are equal.

Let ABCD, EBCF, be parallelograms standing on the same base BC, and between the same parallels BC, AF, they are equal to one another. For since AD is equal to BC, that is to EF, (Th. 12,) therefore AE is equal to DF, now AB is equal to DC (Th. 12;) and the angle BAE to CDF, (Th. 9, Cor.) therefore the triangles BAE and CDF are equal. (Th. 1.) Now if from the whole figure BAFC there be taken away the triangle CDF, there remains the parallelogram ABCD, and if from the same figure there be taken away the equal triangle BAE, there remains

the parallelogram EBCF, therefore these parallelograms are equal to one another.

COR. 1. Hence triangles standing upon the same base, and between the same parallels, are equal to one another.

For let BAC, BEC, be two triangles standing on the same base BC, and between the parallels AF, BC, it is evident that they are the halves of the parallelograms BADC, BEFC, and therefore equal.

COR. 2. Hence if a triangle and parallelogram stand on the same base, the triangle is half of the parallelogram.

COR. 3. Therefore all parallelograms or triangles whatever whose bases and altitudes are equal, are also equal among themselves.

THEOR. XV. fig. 41. The complements of a parallelogram are equal.

Let BD the diagonal of a parallelogram ABCD be drawn, and let HK, EG, parallels to its sides, intersect each other at F a point in the diagonal; the whole parallelogram is thus divided into four parallelograms; two of these, viz. EK, HG, stand about the diameter, and the remaining two HE, GK, are called the complements, and are to be proved equal. The whole triangle DAB is equal to the whole triangle DCB, (Th. 12,) and for the same reason the parts DEF, FHB, are respectively equal to the parts DKE, FGB, therefore the remaining parts HE, GK, must likewise be equal.

THEOR. XVI. fig. 42. In a right-angled triangle the square of the hypotenuse is equal to the sum of the squares upon the other two sides.

Let AD be a square upon the hypotenuse of a right-angled triangle ABC, and BG, BI, squares upon its sides, AD is equal to the sum of BG and BI. Let MBH be parallel to AE meeting GF, produced in H, and let EA, produced, meet GH in N. If from the equal angles GAB, CAN, the angle NAB, common to both, be taken away, there remains NAG equal to BAC, now the angle AGN is equal to ABC, and the side AG is equal to AB, therefore AN is equal to AC (Th. 2,) or to AE; and therefore the parallelograms AM, AH, are equal, (Th. 14, Cor. 3,) but AH is equal to the square BG (Th. 14,) therefore AM is equal to BG, and in the same way it will appear that CM is equal to the square BI, therefore the whole square AD is equal to the sum of the squares BG and BI.

THEOR. XVII. fig. 43. A perpendicular drawn from the centre of a circle to a chord bisects that chord.

Let CD be drawn from the centre C perpendicular to AB a chord in the circle, AD is equal to DB. Join CA, CB. Because AC is equal to CB (def. 3,) the angles CAB, CBA, are equal (Th. 3,) now ADC, BDC, are equal, being right angles, therefore the angles ACD, BCD, are equal, (Th. 10, Cor. 3,) therefore the triangles ACD, BCD, are in all respects equal, (Th. 1,) and consequently AD equal to DB.

COR. A perpendicular bisecting any chord at right angles passes through the centre of the circle.

THEOR. XVIII. fig. 44. A straight line drawn through any point in the circumference of a circle, at right angles to the radius terminating in that point, is a tangent to the circle.

Let AB be perpendicular to the radius AC, the line AB is a tangent to the circle at the point A. Draw CE any line from the centre cutting the circle at D, and the line AB at E. Because CAE is a right angle, CEA is less than a right angle, (Th. 10,) therefore CE is greater than CA, or, than CD, (Th. 11,) therefore the point E is without the circle, and the same may be shewn of every point in AB, except A, therefore AB is a tangent to the circle. (def. 47.)

COR. If a line be perpendicular to a tangent at the point of contact, that line passes through the centre.

THEOR. XIX. fig. 45. An angle at the centre of a circle is double the angle at the circumference which stands upon the same arc.

Let ACB be the angle at the centre of a circle, and ADB the angle at the circumference, the angle ACB is double ADB. Join DC, which produce to E. The angle ACE is equal to both the angles CAD, CDA (Th. 10,) that is, since CD and CA are equal to twice ADC (Th. 3;) in like manner it will appear that BCE is equal to twice BDE; therefore the whole angle ACB is double ADB.

COR. 1. All angles in the same segment of a circle are equal to each other.

COR. 2. In the same circle, or in circles of equal radii, if two angles at the circumference stand upon equal arches, they are equal to one another, and conversely.

THEOR. XX. fig. 46. An angle in a semicircle is a right angle.

Let ACB be an angle in a semicircle, draw the diameter CDE. The angle ACE at the circumference is half of ADE at the centre, and in like manner BCE is half of BDE (Th. 19;) therefore the whole angle ACB is half the sum of the angles ADE, ECB, or is equal to a right angle. (Th. 6.)

THEOR. XXI. fig. 47. The sum of any two opposite angles of a quadrilateral inscribed in a circle, is equal to two right angles.

Let ABCD be a quadrilateral in a circle, the sum of BAD, BCD, also the sum of ADC, ABC, is equal to two right angles. Join AC, BD. The angle BAC is equal to BDC, also the angle DAC is equal to DBC (Th. 19, cor. 1;) therefore the whole angle DAB is equal to the two angles BDC, DBC; and the sum of DAB and DCB is equal to the three angles BDC, DBC, and DCB, that is, equal to two right angles. (Th. 10.)

THEOR. XXII. fig. 48. The angle formed by a tangent to a circle, and a chord drawn to the point of contact, is equal to the angle in the alternate segment of the circle.

Let AB be a tangent, and AC a chord, the angle CAB is equal to any angle CEA in the alternate segment. Draw AF perpendicular to AB, meeting the circle in F, and join EF; thus AF will be the diameter of the circle (Th. 18, cor.) and FEA a right angle (Th. 20); therefore equal to FAB, but FEC, FAC, parts of these angles, are equal. In like manner, the angle CAD is equal to CGA; for FGA is equal to FAD, and FGC to FAC; therefore the wholes CAD, CGA, are equal.

OF RATIOS AND PROPORTIONS.

In the treating of proportion, the algebraic notation is here adopted for the sake of brevity; it will therefore be proper to observe,

1. That the letters A, B, &c. are used to denote quantities of any kind, and the letters m, p, q , &c. to denote numbers only.

2. The sign + (plus) written between the symbols of two quantities or numbers, signifies the sum of those quantities or numbers. Thus $A + B$ means the sum of the quantities denoted by A and B, &c.

3. The sign - (minus) written between the symbols of two quantities, signifies the difference of these quantities. Thus $A - B$ means the difference between A and B.

4. When a letter denoting a number is written close to a letter denoting any quantity, it signifies that the quantity is multiplied by the number; thus mA means m times A; also gmB means that B is multiplied by the product of the numbers g and m .

5. The quotient arising from the division of any quantity A by another quantity B, is written thus $\frac{A}{B}$.

6. The sign = signifies the equality of quantities denoted by the letters that stand on the opposite sides of it. Thus $\frac{mA}{mB} = \frac{A}{B}$ de-

notes that the quotient arising from the division of m times A by m times B is the same as the quotient arising from the division of A by B.

7. It is likewise supposed that the following principle in the arithmetic of fractional quantities is already known, namely, that if both the numerator and denominator of a given fraction be divided by the same number, the resulting quotients are the numerator and denominator of a fraction of the same value as the given one.

It is thus that the fractional quantity $\frac{mA}{mB}$ is concluded to

be equal to $\frac{A}{B}$, viz. by dividing both numerator and denominator by m , and so of other quantities.

DEFINITIONS.

54. When one quantity contains another a certain number of

times exactly, the former is said to be a multiple of the latter; and the latter a part of the former; thus 20 is a multiple of 5, and 5 a part of 20; and, in general, m being any number, and A any quantity, mA is a multiple of A, and A a part of mA .

55. When several quantities are multiples of as many others, and each contains its part of the same number of times, the former are said to be equimultiples of the latter, and the latter like parts of the former; thus 20 and 30 are equimultiples of 2 and 3, and in general mA and mB are equimultiples of A and B; also A and B are like parts of mA and mB .

56. Ratio is the proportion which one magnitude bears to another magnitude of the same kind, with respect to quantity.

Note. The measure, or quantity of a ratio, is conceived by considering what part or parts of the leading quantity called the antecedent is of the other called the consequent. So the ratio of a quantity expressed by the number 2 to a like quantity expressed by the number 6 is denoted by 6 divided by 2, or $\frac{6}{2}$ or 3; the number 2 being 3 times contained in 6, or the third of it, and in general the measure of the ratio of A to B is expressed by the quotient of B divided by A, or the fraction $\frac{B}{A}$.

57. Proportion is an equality of ratios, and three quantities are said to be proportional when the ratio of the first to the second is equal to the ratio of the second to the third. As of the three quantities A (2), B (4), C (8); where $\frac{4}{2} = \frac{8}{4} = 2$, the same ratio.

58. Four quantities are said to be proportional when the ratio of the first to the second is the same as the ratio of the third to the fourth. As of the four quantities A (2), B (4), C (5), D (10); where $\frac{4}{2} = \frac{10}{5} = 2$, the common ratio.

Note. To denote that four quantities A, B, C, D, are proportional, they are usually placed thus, $A : B :: C : D$, and read thus, As A is to B, so is C to D; but when three quantities are proportional, the middle one is repeated, and they are written thus, $A : B :: B : C$.

59. Of three proportional quantities, the middle one is said to be a mean proportional between the other two, and the last a third proportional to the first and second.

60. Of four proportional quantities, the last is said to be a fourth proportional to the other three taken in order.

61. Quantities are said to be continually proportional, or in continued proportion, when the ratio is the same between every two adjoining terms, thus, 1, 2, 4, 8, 16, &c. are in continued proportion.

62. In a series of quantities continually proportional, the ratio of the first and third is said to be duplicate to that of the first and second; and the ratio of the first and fourth is said to be triplicate to that of the first and second, and so on.

63. Inverse ratio is, when the antecedent is made the consequent, and the consequent the antecedent; thus, if $1 : 2 :: 3 : 6$; then inversely $2 : 1 :: 6 : 3$.

64. Alternate proportion is, when antecedent is compared with antecedent, and consequent with consequent, as if $1 : 2 :: 3 : 6$; then by alternation or permutation, $1 : 3 :: 2 : 6$.

65. Compounded ratio is, when the sum of the antecedent and consequent is compared, either with the antecedent or consequent, thus, if $1 : 2 :: 3 : 6$; then by composition, $1 + 2 : 1 :: 3 + 6 : 3$, and $1 + 2 : 2 :: 3 + 6 : 6$.

66. Divided ratio is, when the difference of the antecedent and consequent is compared, either with the antecedent or consequent, thus, if $1 : 2 :: 3 : 6$, then by division $2 - 1 : 1 :: 6 - 3 : 3$; also $2 - 1 : 2 :: 6 - 3 : 6$.

THEOR. XXIII. Equimultiples of any two quantities are in the same ratio as the quantities themselves.

Let A and B be any two quantities, and mA, mB , any equimultiples of them, m being any number whatever; then will mA and mB have the same ratio as A and B, or $A : B :: mA : mB$.

For $\frac{mA}{mB} = \frac{A}{B}$, both the same ratio.

COR. Hence, like parts of quantities have the same ratio as the wholes, because the wholes are equimultiples of the like parts, or A and B are like parts of mA and mB .

THEOR. XXIV. If four quantities of the same kind are proportional,

portional, they will be proportional also by alternation or permutation, or the antecedents will have the same ratio as the consequents.

Let $A : B :: mA : mB$, then will $A : mA :: B : mB$.

For $\frac{A}{mA} = m$ and $\frac{B}{mB} = m$, both the same ratio.

THEOR. XXV. If four quantities are proportional, they will be proportional also by inversion, or inversely.

Let $A : B :: mA : mB$, then will $B : A :: mB : mA$.

For $\frac{B}{mB} = \frac{A}{mA}$, both the same ratio.

THEOR. XXVI. If four quantities be proportional, they will also be proportional by composition, and by division.

Let $A : B :: mA : mB$.

Then will $B + A : A :: mB + mA : mA$.

or, $B + A : B :: mB + mA : mB$

For $\frac{B + A}{mA} = \frac{B + A}{A}$ and $\frac{mB + mA}{mB} = \frac{B + A}{B}$

In like manner it will appear that

$B - A : A :: mB - mA : mA$.

or, $B - A : B :: mB - mA : mB$.

For $\frac{B - A}{mA} = \frac{B - A}{A}$ and $\frac{mB - mA}{mB} = \frac{B - A}{B}$

THEOR. XXVII. If of four proportional quantities there be taken any equimultiples whatever of the two antecedents, and any equimultiples whatever of the two consequents, the quantities resulting will be still proportional.

Let $A : B :: mA : mB$, also let pA and pmA be any equimultiples, of the two antecedents, and qB and qmB any equimultiples of the two consequents, then will $pA : qB :: pmA : qmB$.

For $\frac{qmB}{pmA} = \frac{qB}{pA}$, the same ratio.

THEOR. XXVIII. If there be four proportional quantities, and the two consequents be either augmented or diminished, by quantities that have the same ratio as the respective antecedents, the results and the antecedents will still be proportional.

Let $A : B :: mA : mB$, and nA and nmA any two quantities having the same ratio as the two antecedents; then will.

$A : B + nA :: mA : mB + nmA$.

Also $A : B - nA :: mA : mB - nmA$.

For $\frac{mB \pm nmA}{mA} = \frac{B \pm nA}{A}$, the same ratio.

THEOR. XXIX. If any number of quantities be proportional, any one of the antecedents will be to its consequent, as the sum of all the antecedents to the sum of all the consequents.

Let $A : B :: mA : mB :: nA : nB$, &c.

Then will be $A : B :: A + mA + nA : B + mB + nB$, &c.

For $\frac{B + mB + nB}{A + mA + nA} = \frac{B}{A}$, the same ratio.

THEOR. XXX. If a whole magnitude be to a whole, as a quantity taken from the first to a quantity taken from the other, the remainder is to the remainder, as the whole is to the whole.

Let $A : B :: \frac{m}{n}A : \frac{m}{n}B$.

Then will $A : B :: A - \frac{m}{n}A : B - \frac{m}{n}B$.

For $\frac{A - \frac{m}{n}A}{B - \frac{m}{n}B} = \frac{A}{B}$, the same ratio.

THEOR. XXXI. If there be two sets of proportionals; then the products or rectangles of the corresponding terms are also proportional.

Let $A : B :: mA : mB$.

And $C : D :: nC : nD$,

then will $AC : BD :: mnAC : mnBD$, where AC represents the product or rectangle of A and C , and BD the product or rectangle of B and D .

For $\frac{mnBD}{mnAC} = \frac{BD}{AC}$, the same ratio.

COR. 1. If there be any number of sets of proportionals; the products of the corresponding terms are proportional.

COR. 2. If four quantities be proportional, their squares and cubes are also proportional, and in general any powers of them are proportional.

THEOR. XXXII. If four quantities be proportional, the rectangle or product of the two extremes is equal to the rectangle or product of the two means.

Let $A : B :: mA : mB$.

Then is $A \times mB = B \times mA = mAB$, as is evident.

COR. If three quantities be continual proportionals, the rectangle or product of the extremes will be equal to the square of the mean.

THEOR. XXXIII. fig. 49. Triangles and also parallelograms having the same altitude, or that are between the same parallels, are to one another in the same ratio as their bases.

Let the triangles ADC , DEF , have the same altitude, or be between the same parallels AE , CF , then $AD : DE ::$ Triangle ADC : Triangle DEF . For let AD contain a number of parts, m of which DE contains the number n , and call each of the parts A , and since triangles are equal, there will be a number of triangles in ADC denoted by m , and in DEF a number denoted by n , all equal among themselves: call each of them B ; then $AD = mA$, $DE = nA$, the triangle $ADC = mB$, and $DEF = nB$,

but $\frac{nB}{mB} = \frac{nA}{mA}$, that is, the triangle $ADC : DEF :: AD : DE$.

In like manner the parallelogram $ADCI$ is to the parallelogram $DEFG$ as the base AD to the base DE .

COR. fig. 50. Triangles and parallelograms having equal bases are to one another as their altitudes. For let ABC , BFE , be triangles having their equal bases AB , BE , in the same straight line AE ; let BK be perpendicular to AE , draw CK , FL , parallel to AE , and join AK , AL . The triangles ACB , AKB , are equal; also the triangles ALB , BFE . (Th. 16. Cor. 3.) And by the theorem the triangle AKB is to the triangle ALB as KB to LB , but KB and LB are equal respectively to CG and FH the altitudes of the triangles ACB , BFE ; therefore the triangles ACB , BFE , are to each other as their altitudes.

THEOR. XXXIV. fig. 51. If a line be drawn in a triangle parallel to one of its sides, it cuts the two other sides proportionally.

Let DE be drawn parallel to BC one of the sides of the triangle ABC , then $AD : DB :: AE : EC$. Join BE and CD . The triangles BDE , CDE , are equal (Th. 14. Cor. 1.) therefore, since any magnitude must necessarily have the same ratio to each of two equal magnitudes, the triangle ADE is to the triangle BDE as the same triangle ADE is to the triangle CDE , but ADE is to EDB as AD to DB (Th. 33,) and ADE is to EDC as AE to EC ; therefore $AD : DB :: AE : EC$.

COR. 1. Hence also the whole lines AB , AC , are proportional to their proportional segments (Cor. Th. 23,) namely $AB : AC :: AD : AE$, and $AB : AC :: BD : CE$.

COR. 2. A straight line which divides the sides of a triangle proportionally is parallel to the remaining side.

THEOR. XXXV. fig. 52. If a line bisect the vertical angle of a triangle and meet the base, the segments of the base will be directly proportional to the other two sides of the triangle.

In the triangle ABC let BD bisect the vertical angle, then $AB : BC :: AD : DC$. For, draw CE parallel to DB , meeting AB produced in E . The angle ECB is equal to CBD (Th. 9,) or to DBA (by hyp.) that is to CEA or CEB (Th. 9, Cor.) therefore CB is equal to BE (Th. 4.) In the triangle AEC , the line BD is parallel to EC , therefore $AB : BE :: AD : DC$, or since BE is equal to BC , $AB : BC :: AD : DC$.

COR. Hence, conversely, if a line be drawn from the vertex of a triangle

a triangle to divide the base into segments directly proportional to the sides, that line will bisect the vertical angle.

THEOR. XXXVI. fig. 53. Equiangular triangles are similar, or have their like sides proportional.

Let ABC , DEF , be two equiangular triangles having the angle A equal to the angle D , the angle B to the angle E , and consequently the angle C to the angle F , then will $AB : AC :: DE : DF$. Take DG equal to AB , and DH to AC , and join HG . Then the triangles ABC , DGH are equal in all respects, (Th. 1,) namely, the angles B and C equal to the angles G and H , but B and C are equal to E and F , (by hyp.) therefore G and H are equal to E and F , and consequently GH is parallel to EF , (Th. 8, Cor.), therefore $DG : DH :: DE : DF$ (Th. 34, Cor. 1.) but DG and DH are equal to AB and AC , therefore $AB : AC :: DE : DF$.

THEOR. XXXVII. fig. 53. Triangles which have their sides proportional are equiangular.

In the triangles ABC , DEF , if $AB : AC :: DE : DF :: BC : EF$, the triangles will have their corresponding angles equal. Take DH equal to AC , and DG equal to AB . Then $DG : DH :: DE : DF$, therefore GH is parallel to EF (Th. 34, Cor. 2); hence the triangles DGH , DEF are equiangular (Th. 9); wherefore $DG : GH :: DE : EF$ (Th. 36) :: $AB : BC$ (by hyp.); since therefore $DG : GH :: AB : BC$, and that DG is equal to AB , therefore GH is equal to BC . Thus the triangles DGH , ABC , having the three sides of the one respectively equal to the three sides of the other, are equiangular (Th. 5,) therefore also the triangles ABC , DEF , are equiangular.

THEOR. XXXVIII. fig. 53. Triangles which have one angle to the one equal to one angle in the other, and the sides about these angles proportional, are equiangular.

Let ABC , DEF , be two triangles having the angles A and D equal, and $AB : AC :: DE : DF$; these triangles shall be equiangular. Make DG equal to AB , and DH to AC , and join HG : thus the triangles ABC , DGH , are identical and equiangular (Th. 1); therefore $HD : DG :: CA : AB :: FD : DE$ (by hyp.); therefore HG is parallel to FE , (Th. 34, Cor. 2,) and the triangles HGD , FDE , also CAB , FDE , are equiangular.

THEOR. XXXIX. fig. 54. If four lines are proportional, the rectangle of the extremes will be equal to the rectangle of the means; and if the rectangle of the extremes be equal to the rectangle of the means, the four lines are proportional.

Let the four lines A , B , C , D be proportional, or $A : B :: C : D$, then will the rectangle of A and D be equal to the rectangle of B and C . Let the four lines be placed with their extremities meeting at a common point, and forming four right angles; and draw lines parallel to them to complete the rectangles P , Q , R ; where P is the rectangle of A and D , Q the rectangle of B and C , and R the rectangle of B and D . Then the rectangles P and R will be to each other as A and B (Th. 33,) and in like manner the rectangles Q and R will be to each other as C and D ; but the ratio of A to B is the same as the ratio of C to D ; therefore the ratio of P to R is the same as the ratio of Q to R , and consequently P and Q are equal.

Again, if the rectangle of A and D be equal to the rectangle of B and C , $A : B :: C : D$. For the rectangles being placed as before, it is evident that P and Q have each the same ratio to R ; but P is to R as A to B , and Q to R as C to D , therefore $A : B :: C : D$.

COR. If three lines are proportional, the rectangle of the extremes is equal to the square of the mean: and if the rectangle of the extremes be equal to the square of the mean, the three lines are proportional.

THEOR. XL. fig. 55 and 56. If two lines meeting a circle cut each other, either within it, or without, the rectangle of the parts of the one will be equal to the rectangle of the parts of the other; the parts of each being measured from the point of meeting to the two intersections with the circumference.

Let the two chords AB , CD , meet each other in E , the rectangle of AE , EB , is equal to the rectangle of CE , ED . Join AD , and CB . The triangles AED , CEB , are equiangular, for the angles at D and B are equal (Th. 19, Cor. 1,) and the angles AED , CEB , are opposite (fig. 54,) and therefore equal (Th. 7): or the angle at E is common to both triangles (fig. 57,) in either case the triangles are equiangular; therefore $DE : EA :: EB : EC$ (Th. 36); hence the rectangle of DE , EC , is equal to the rectangle of AE , EB , (Th. 39.)

COR. If the line BAE , (fig. 56,) be supposed by revolving to come into the position of the tangent AE , (fig. 57,) the distances BE , AE , will thus have become equal. Hence we have this Theorem. If from a point without a circle two lines be drawn, one touching it, and the other cutting it, the rectangle of the distances of that point from the intersections of the cutting line, or secant, is equal to the square of the tangent.

THEOR. XLI. fig. 58. In a right-angled triangle, a perpendicular from the right angle is a mean proportional between the segments of the hypotenuse; and each of the sides about the right angle is a mean proportional between the adjacent segment, and the hypotenuse.

Let ABC be a right-angled triangle, and CD a perpendicular upon the hypotenuse; then will $AD : DC :: DC : DB$, and $AB : AC :: AC : AD$, and $AB : BC :: BC : BD$.

For the triangles ACB , ADC , having the right angles at C and D equal, and the angle at A common, have their third angles equal, and are equiangular; and in like manner it will appear that the triangles ACB , CDB , are equiangular. Hence these three triangles ACB , ADC , CDB , being equiangular, will have the sides about the equal angles proportional; thus we get $AD : DC :: DC : DB$, and $AB : AC :: AC : AD$, and $AB : BC :: BC : BD$, (Th. 36.)

THEOR. XLII. fig. 59. Equiangular or similar triangles are to each other as the squares of their like sides.

Let ABC , DEF , be two equiangular triangles, AB and DE being their homologous or like sides, and AL , DN , squares on these sides. The triangle ABC is to the triangle DEF as the square AL to the square DN . Draw CG and FH perpendicular to AB and DE , and join BK and EM . The triangles ACG , DFH , are equiangular (Th. 10, Cor. 3); therefore $AC : DF :: CG : FH$ (Th. 36); but the triangles ABC , DEF , being equiangular, we have $AC : DF :: AB : DE$; therefore, from equality of ratios, we have $CG : FH :: AB : DE :: AK : DM$, and by alternation, $CG : AK :: FH : DM$. Now $CG : AB ::$ triangle ABC : triangle ABK , (Th. 33, Cor.); and in like manner $FH : DM ::$ triangle DEF : triangle DME , therefore triangle ABC : triangle $ABK ::$ triangle DEF : triangle DME , and by alternation, triangle ABC : triangle $DEF ::$ triangle ABK : triangle DME . But the squares AL , DN , being the doubles of the triangles ABK , DME , have the same ratio with them. Therefore the triangle ABC is to the triangle DEF , as the square AL to the square DN .

THEOR. XLIII. fig. 60. Similar rectilineal figures are to each other as the squares of their like sides.

Let $ABCDE$, $FGHK$, be two similar figures, the like sides being AB and FG , BC and GH , and so on; the figure $ABCDE$ will be to the figure $FGHK$ as the square of AB to the square of FG . Join BE , BD , GK , GI . Because the angles A and F are equal, and $BA : AE :: GF : FK$, the triangles BAE , GFK , are equiangular (Th. 38,) hence $AE : EB :: FK : KG$, but $AE : ED :: FK : KI$ (by hyp.), therefore $BE : ED :: GK : KI$. Now the angles AED , FKI , are equal, and the angles AEB , FKG , have been proved equal; therefore the angles BED , GKI , are equal; thus the triangles BED , GKI , are also equiangular, and in the same way it may be shewn that the triangles BDC , GIH , are equiangular. The triangle ABE is to FGK as the square of BE to the square of GK , that is, as the triangle EBD to the triangle KGI , (Th. 42,) and in like manner it will appear, that EBD is to KGI as DBC to IGH : therefore the whole figure $ABCDE$ is to the figure $FGHK$, as the triangle ABE to the triangle FGK (Th. 29); that is, as the square of AB to the square of FG , (Th. 42.)

COR. 1. Circles are to one another as the squares of their diameters. And in general, that all similar plane figures whatever, are to one another as the squares of lines similarly drawn in them.

For let $ABCDEF$, $GHIKLMN$, (fig. 61,) be any two regular polygons, of the same number of sides, inscribed in circles whose diameters are AD , GL . Draw AO , FO , to the centre of the one polygon, and GP , NP , to the centre of the other. The angles AOF , GPN , standing each upon the same part of the whole circumference, are evidently equal, and consequently the isosceles triangles, AOF , GPN , are similar: thus it appears that each of the polygons is made up of the same number of similar triangles; therefore the polygon $ABCDEF$, is to the polygon $GHIKLMN$, as the triangle AOF to the triangle GPN ; that is, as the square

of AO to the square of GP, or as the square of the diameter AD to the square of the diameter GL. Now whatever be the number of the sides of the polygon, it is evident, that their proportion to each other will be the same; namely, that of the squares of the diameters of their circumscribing circles. By supposing the number of the sides of the polygons continually increased, it is evident that their areas will approach more and more to the areas of their circumscribing circles, which may be considered as their limits; for it may be demonstrated, that a polygon may have its sides so numerous as to differ from the area of its circumscribing circle by less than any assignable quantity. Hence we may conclude, that the areas of the circles themselves have to each other the same proportion as their inscribed polygons; namely that of the squares of the diameters.

COR. 2. If circles or any similar plane figures be described on the three sides of the right-angled triangle, that on the hypotenuse is equal to the other two.

For since the two squares GB, GI, on the sides of the right-angled triangle ABC (fig. 42,) are equal to the square AD, (Th. 16,) and similar figures described on the lines are as the squares, we have as the square AD to the figure on AC, so is the square GB to the similar figure on AB, and so is the square BI, to the similar figure on BC: therefore AD is to the figure on AC as GB and BI to the figure on AB and BC, (Th. 29); but $AD = GB + BI$, therefore the figure AC is equal to those on AB and BC.

Of PLANES and SOLIDS.

DEFINITIONS.

67. The common section of two planes, is the line in which they meet, or cut each other.

68. A straight line is perpendicular to a plane, when it is perpendicular to every line which meets it in that plane.

69. One plane is perpendicular to another, when every right line in the one, which is perpendicular to their line of common section, is perpendicular to the other.

70. The inclination of one plane to another, or the angle they form between them, is the angle contained by two right lines, drawn from any point in the common section, and at right angles to the same.

71. Parallel planes are such as being produced ever so far both ways, will never meet, or which are every where at an equal perpendicular distance.

72. A solid is that which has length, breadth, and thickness.

73. Similar solids are such as are bounded by an equal number of similar planes.

74. A prism is a solid, of which the sides are parallelograms, and the two ends or bases are similar and equal polygons, parallel to each other. Prisms are denominated according to the number of angles in the base, triangular prisms, quadrangular, heptangular, and so on, as figs. 62, 63, 64, 65. If the sides are perpendicular to the plane of the base, it is called an upright prism; if they are inclined, it is called an oblique prism.

75. When the base of a prism is a parallelogram, it is called a parallelopipedon, as figs. 64 and 65. Hence a parallelopipedon is a solid terminated by six parallelograms.

76. When all the sides of the parallelopipedon are squares, the solid is called a cube, as fig. 65.

77. A rhomboidal prism is an oblique prism, whose bases are parallelograms (fig. 66.)

78. A pyramid (figs. 67 and 68,) is a solid bounded by, or contained within, a number of planes, whose base may be any polygon, and whose faces are terminated in one point, B, commonly called the vertex of the pyramid.

79. When the figure of the base is a triangle, it is called a triangular pyramid; when the figure of the base is a quadrilateral, it is called a quadrilateral pyramid, &c.

80. A pyramid is either regular or irregular, according as the base is regular or irregular.

81. A pyramid is also right or upright, or it is oblique. It is right, when a line drawn from the vertex to the centre of the base, is perpendicular to it, as fig. 67, and oblique, when this line inclines, as fig. 68.

82. A cylinder is a solid (figs. 69 and 70,) generated by the ro-

tation of a rectangle about one of its sides, supposed to be at rest; this quiescent side is called the axis of the cylinder. Or it may be conceived to be generated by the motion of a circle, in a direction perpendicular to its surface, and always parallel to itself.

83. A cylinder is either right or oblique, as the axis is perpendicular to the base or inclined.

84. A cone is a solid (figs. 71 and 72,) having a circle for its base, and its sides a convex surface, generated by a line revolving about the circle, on a fixed point as A, called the vertex or apex of the cones.

85. A line drawn from the vertex to the centre of the base is the axis of the cone.

86. When this line is perpendicular to the base, the cone is called an upright, or right cone, fig. 71; but when it is inclined it is called an oblique cone, fig. 72.

87. A sphere is a solid, terminated by a convex surface, every point of which is at an equal distance from a point within, called the centre, (fig. 76.) It may be conceived to be formed by the revolution of a semicircle round its diameter. The diameter of the semicircle round which it revolves, is called the axis of the sphere.

88. A spheroid is a solid (fig. 77,) generated by the rotation of a semi-ellipsis about the transverse or conjugate axis; and the centre of the ellipsis is the centre of the spheroid.

89. The spheroid is denominated prolate or oblate respectively according as the ellipsis revolves on the transverse or conjugate diameter.

THEOR. XLIV. fig. 78. A perpendicular is the shortest line that can be drawn from any point to a plane.

Let AB be perpendicular to the plane DE, then any other line, as AC, drawn from the same point A to the plane, will be longer than AB. Join BC; then ABC is a right angle, hence BCA is less than a right angle, and consequently BA less than AC. (Th. 11.)

COR. A perpendicular measures the distance of any point from a plane.

THEOR. XLV. fig. 79. The common section of two planes is a straight line.

Let ACBDA, AEBFA, be two planes cutting each other, and A, B, two points in which the two planes meet; the straight line joining these points will be the common intersection of the planes. For, because the straight line AB touches both planes at the points A, B, it touches them in all points (Def. 5); this line is therefore common to both planes, that is, their common intersection is a straight line.

THEOR. XLVI. fig. 80. If a straight line be perpendicular to two other straight lines, at their common intersection, it will be perpendicular to the plane of those straight lines.

Let the line AB make right angles with the lines AC, AD, it will be perpendicular to the plane CDA, which passes through these lines. For, if the line AB were not perpendicular to the plane CDE, another plane might pass through the point A, to which AB would be perpendicular; but this is impossible, for since the angles BAC, BAD, are right angles, this other plane must pass through the points C, D. Hence this plane passing through the points A, C of the line AC, and also through the points A, D, of the line AD, it will pass through both these lines, and therefore be the same plane with the former.

COR. If a straight line stand at right angles to each of three straight lines at the same point, these three lines are in one plane.

THEOR. XLVI. fig. 81. If two straight lines be perpendicular to the same plane, they will be parallel to each other.

Let AB and CD be both perpendicular to the plane EF; these lines are parallel. Join the points B and D, and draw DG perpendicular to BD, in the plane EF; make DG equal to BA, and join AD, AG. The triangles BDG, DBA, have the sides DG, BA, equal, and BD common to both; the angles BDG, DBA, are also equal, being right angles; therefore these triangles are identical, (Th. 1,) hence BG is equal to AD, and the triangles ABG, GDA, have two sides AB, BG, of the one, equal to two sides GD, DA, of the other, each to each, and the side AG common to both; therefore these also are identical (Th. 5,) hence the angle ADG is equal to ABC, that is to a right angle. Hence

it appears that DG is perpendicular to the lines BD, AD ; and it is also perpendicular to DC ; (Def. 68.) Therefore the lines BD, DA, DC , are in the same plane. (Th. 46. Cor.) Since AB, CD , are in the same plane, and both perpendicular to BD , they are parallel. (Th. 8.)

COR. If two lines be parallel, and one of them perpendicular to any plane, the other will also be perpendicular to the same plane.

THEOR. XLVIII. fig. 82. If two planes cut each other at right angles, and a straight line be drawn in one of the planes, perpendicular to their common intersection, it will be perpendicular to the other plane.

Let the planes $ACBD, AEBF$, cut each other at right angles, and the line CG be perpendicular to their common section AB ; then will CG be perpendicular to the plane $AEBF$. For, let EG be perpendicular to AB , thus the angle CGE is the angle of inclination of planes, (Def. 70,) and is therefore a right angle; since therefore the line CG is perpendicular to the two lines AG, GE , it is perpendicular to the plane $AEBF$, in which these lines are drawn. (Th. 46.)

THEOR. XLIX. fig. 83. Planes, which are perpendicular to the same straight line, are parallel to one another.

Let the planes EF, GH , be perpendicular to AB , they are parallel; if not, let them meet, and let C be a point in the common section, join AC and BC , then the angles CBA, CAB , are right angles, which is impossible (Th. 10. Cor. 2); hence the planes do not meet, and are therefore parallel. (Def. 71.)

COR. Hence straight lines perpendicular to one of two parallel planes are also perpendicular to the other plane.

THEOR. L. fig. 84. If two straight lines be parallel to a third line, though not in the same plane with it, they will be parallel to each other.

Let AB, CD , be each parallel to the same line EF , though not in the same plane with it, AB shall be parallel to CD . For, let GH and GI be perpendicular to EF , in the planes AF and DE of the parallels; then shall GF be perpendicular to the plane passing by HGI (Th. 46.); and HB, ID , will also be perpendicular to the same plane (Th. 47. Cor.), and therefore parallel. (Th. 47.)

THEOR. LI. fig. 85. If two lines that meet each other, be parallel to two other lines that meet each other, though not in the same plane with them; the angles contained by these lines will be equal.

Let the lines AB, AC , be parallel to the lines DE, DF , then will the angles BAC, EDF , be equal. For, take AB, AC, DE, DF , all equal, and join EB, FC, BC, EF . Then the lines AB, DE , being equal and parallel, the lines AD, BE , will also be equal and parallel, (Th. 13,) and for the same reason AD, CF , are equal and parallel; therefore CF is parallel to BE , (Th. 50,) and also equal to it; hence BC is equal to EF . Thus the triangles ABC, DEF , are in all respects equal, (Th. 5,) and therefore the angles BAC, EDF , are equal.

THEOR. LII. fig. 86. The sections made by a plane cutting two parallel planes are also parallel to each other.

Let the parallel planes AB, CD , be cut by the third plane, $EFHG$, in the line EF, GH . These lines are parallel. For, suppose, EG, FH , to be drawn parallel to each other in the plane $EFHG$; also, let EI, FK , be perpendicular to the plane CD , and let IG, KH , be joined: then EG, FH , being parallels, and EI, FK , being both perpendicular to the plane CD , are also parallel to each other, (Th. 47,) therefore the angle HFK is equal to the angle GEL (Th. 51,) but the angles FKH, EIG , are equal, being right angles; therefore the triangles FKH, EIG , are equiangular, (Th. 10, Cor. 3,) and the sides FK, EI , being equal, (Def. 71,) it follows, that the sides FH, EG , are also equal, (Th. 2;) but these two lines are parallel, (by hyp.) as well as equal; therefore also EF and GH , which join their extremities, are parallel. (Th. 13.)

THEOR. LIII. If from two cubes, parts similar, and similarly situated, be cut off, these parts are to one another as the cubes from which they are cut.

Let the cubes be FB and fb , fig. 87, and let $LHIK$ be the planes by which the cubes are cut, then the parts are proportional to the whole cubes.

For let BA, AE , be divided into an equal number of equal parts, and ba, ae , into the same number, and through the points

of division on each side let planes pass parallel to the other sides, then the two cubes will be divided into an equal number of small cubes, and those of each cube equal among themselves; therefore as one of the cubes in FB , is to one in fb , so is the cube FB , to the cube fb , (Th. 23). Again, because the parts cut off are similar, and similarly situated, their terminating planes and lines are cut proportionally by the planes, forming the cubes, into which the whole is divided; hence there is an equal number of cubes in the parts cut off; and the magnitudes which remain in the parts cut off, besides the entire cubes, are divided into an equal number of cubes, by taking the divisions in BA, ba , less; therefore, as one of the cubes in FB is to one in fb , that is as the cube FB is to fb , so is the part cut from FB , to the similar part cut off from fb .

COR. 1. If several parts similar, and similarly situated, be cut from two cubes, the like parts are to one another, as the whole cubes from which they were cut off.

COR. 2. Any two similar solids may be considered as being similarly cut from two cubes, which are to one another as those solids; or which is the same thing, the solids may be considered as similarly situated in the cubes; and hence are like parts of them.

THEOR. LIV. Similar solids are to one another as the cubes of their like sides.

Let AB, ab , fig. 87, be the like sides of any two similar solids, these solids shall be to one another as FB , the cube on AB , to fb , the cube on ab .

For let two cubes A and B be taken, so that A may be to B , as the solid figure on AB to the similar solid figure on ab , and let the solid on AB be situated in the cube A , and the solid on ab similarly situated in the cube B , then are they like parts of the cubes A and B ; also on AB , and ab , in the cubes A and B . Let the cubes FB and fb be similarly situated, then in the same manner the cubes FB and fb are like parts of A and B , therefore $A : B :: FB : fb$, but $A : B ::$ the solid figure on AB , to the similar solid figure on ab ; therefore the solid on AB , is to the similar solid on ab , as the cube on AB , to the cube on ab .

COR. Hence globes are as the cubes of their diameters.

THEOR. LV. If a prism be cut by a plane parallel to the base, the section will be equal and like to the base.

Let AG , fig. 88, be a prism, IL a section parallel to the base AC ; IL is equal and similar to AC .

For IM and AD are parallel, being the common sections of parallel planes, with a third plane (Th. 52.); also IA, MD , are parallel (Def. 74); therefore ID is a parallelogram; hence IM is equal AD , and thus $KL = BC$, and $LM = CD$, and because the corresponding sides are parallel, their contained angles are equal (Th. 51); therefore, the sections are equal and similar.

COR. The same is true of cylinders; for if MLK be the axis, and any sections MC, MB , be drawn through MK , it may be demonstrated as above, that LI, LH , are equal to KC, KB ; hence CHI is a circle equal to ABC . Fig. 89.

THEOR. LVI. All prisms of equal bases and altitudes are equal.

Let AC and DF , fig. 90, be two prisms, and a cylinder, having their bases and altitudes equal, they are equal to one another. For, let PQ, RS , be any two sections parallel to the bases and equidistant from them. Then since these sections are equal to the bases (Th. 55); and the bases equal to one another, these sections are equal to one another. Since then the corresponding sections are every where equal, the prisms of which they are the sections are equal.

THEOR. LVII. Rectangular parallelopipedons, of equal altitudes, are to one another as their bases.

Let AC, EG , fig. 91, be two rectangular parallelopipedons having equal altitudes, $AC : EG ::$ the base $AB : EF$.

For conceive the base AB to be divided into any number of equal parts m , by lines IL, KM , parallel to BN , and through these let planes be passed parallel to AQ , and let EG , be divided in the same manner, having a number of parts n in the base EF each equal those in the base AB ; then because prisms of equal bases and altitudes are equal, AC and EG will be divided into equal prisms, AC into the number m , and EG into the number n , therefore, $AC : EG :: m : n :: AB : EF$.

COR. From this, and the last, it appears that all prisms and cylinders of equal altitudes are as their bases.

THEOR. LVIII. If a section of a pyramid be parallel to the base,

base, it is also similar to it, and these two planes are to one another, as the squares of their distances from the vertex.

Let ABCD, fig. 92, No. 1, be a pyramid, BD the base, and EG parallel to it, and AIH a perpendicular from the vertex: EG is similar to BD, and BD: EG:: AH²: AI².

For, join CH, FI. Then because the planes BD, EG are parallel, their corresponding sides are parallel, being the common sections of parallel planes with a third plane; therefore the corresponding angles are equal (Th. 51.): also AC: AF:: BC: EF:: CD: FG (Th. 34): therefore BD and EG are similar (Def. 52). Again, BD: EG:: BC²: EF² (Th. 43); but by similar triangles BC²: EF²:: CA²: FA²:: HA²: IA²; therefore BD: EG:: HA²: IA².

COR. The section of a cone parallel to the base is a circle, which is to the base, as the squares of their distances from the vertex. For let MPQ, MKR, No. 3, be sections, passing through the axis MK, MLT, perpendicular to the base, and NS, the parallel section; it may be shewn as above, that OS, OW, ON, are parallel and proportional to KQ, KR, and KP; hence they are equal, and the section is a circle; and as above, TM²: LM²:: KR²: OW²:: cir. PRQ: cir. NWS.

THEOR. LIX. Pyramids and cones of equal bases and altitudes are equal.

Let ABC, MPQ, fig. 92, be any pyramids, and cone, having equal bases and altitudes, they are equal to one another.

For, let EG, NS, be sections, parallel to the bases and at equal altitudes; then since these planes are as the squares of the distances from the vertex, (Th. 58.) and since the bases are equal, and the distances from the vertex respectively equal, the sections are equal to one another; and because all the corresponding sections are equal; the solids ABC, MPQ, are also equal.

THEOR. LX. A triangular prism, is three times a pyramid of the same base and altitude.

Let AEF, fig. 93, be the prism, it is three times the pyramid, BDEF, having the same base and altitude. For join BD, BF, and CD; then the prism is divided into three pyramids BDEF, DABC, DBCF; the first two are equal because they have equal bases, ABC, EDF, and equal altitudes, (Def. 74, and Th. 59); also the pyramid DBCF is equal to BDEF, for EBF, (being taken for the base) is equal to CBF, (Th. 12.) and they have the common vertex D; therefore, the three pyramids are equal; and therefore, the prism is triple of any one of them.

COR. 1. Every pyramid is the third part of a prism of the same base and altitude. For every prism, may be divided into triangular prisms.

COR. 2. A cone is the third part of a cylinder of equal base and altitude. For a cylinder is equal to a prism, and a cone to a pyramid of equal base and altitude.

COR. 3. Pyramids and cones of equal altitudes, are as their bases. For the prisms, of which they are the third part, are as their bases. (Th. 57.)

THEOR. LXI. A sphere is two-thirds of its circumscribing cylinder.

Let ABCD, fig. 94, be a cylinder, circumscribing the sphere EFGH. The sphere is two thirds of the cylinder. For let AC, be a section passing through the common axis of the sphere and cylinder, join NA, NB, NI, and draw OIL parallel to AB or EG; it is evident, ANB, is the section of a cone having the same base with the cylinder, and vertex N; and that KL, KI, and KM, are the radii of the circular sections (parallel to the base) of the cylinder, sphere, and cone, respectively; and since NF, is equal to FB, NK is equal to KM; but a circle described on the radius NI is equal to the two circles on NK, KI, (Th. 43, Cor. 2); therefore, the circle on the radius KL is equal to the two circles on the radii KI, KM; hence the section of the cylinder is always equal to the corresponding sections of the sphere and cone. But the cone is a third part of the cylinder; therefore, the sphere is two-thirds of it, or the whole sphere is two-thirds of its circumscribing cylinder.

COR. A cone, hemisphere, and cylinder, of the same base and altitude are to each other as the numbers 1, 2, 3.

We have now delivered the most useful part of Theoretical Geometry: to those who wish to pursue the subject further, we recommend a careful perusal of the works of Euclid, Apollonius, and Archimedes.

What has already been demonstrated in this treatise will be found sufficient for connecting Geometry with Algebra, Conic Sections, Perspective, Navigation, Trigonometry, plane and spherical, and the different branches of mixed Mathematics, such as Optics, &c. all which are treated in their order, in this work. We shall, therefore, in the second part, on Practical Geometry, concisely state the method and rules by which geometry is to be applied to a few easy but useful geometrical problems, and to the mensuration of all the figures, whether superficial or solid, that commonly occur in the ordinary affairs of life.

PRACTICAL GEOMETRY.

GEOMETRICAL PROBLEMS.

PROBLEM I. fig. 95. To divide a given line AB into two equal parts.—1. From the points A and B as centres, with any distance greater than half AB, describe arcs cutting each other in *m* and *n*. 2. Through these points draw the line *mn*, and the point E, where it cuts AB, will be the middle of the line required.

PROB. II. fig. 96. To divide a given angle ABC, into two equal parts.—1. From the point, B, with any radius, describe the arc AC. 2. And from A and C with the same, or any other radius, describe arcs cutting each other in *n*. 3. Through the point *n* draw *nB*, and it will bisect the angle ABC, as was required.

PROB. III. fig. 97, 98. From a given point C, in a given straight line AB, to erect a perpendicular.

CASE I. When the point is near the middle of the line. Fig. 97.—1. On each side of the point C, take any two equal distances *Cn*, *Cm*. 2. From *n* and *m*, with any radius greater than *Cn* or *Cm*, describe arcs cutting each other in *s*. 3. Through the point *s* draw the line *sC*, and it will be the perpendicular required.

CASE II. When the point is at or near the end of the line. Fig. 98.—1. Take any point *o* and with the radius or distance *oC*, describe the arc *mCn*, and draw *mon*, cutting the arc *mCn* in *n*. 2. From the point *n* draw the line *nC*, and it will be the perpendicular required.

PROB. IV. fig. 99, 100. From a given point C, out of a given line AB, to let fall a perpendicular.

CASE I. When the point is nearly opposite to the middle of the line. Fig. 99.—1. From the point C, with any radius, describe the arc *mCn*, cutting AB in *n* and *m*. 2. From the points *n* and *m*, with the same or any other radius, describe two arcs cutting each other in *s*. 3. Through the points *Cs* draw the line *CGs*, and *CG* will be the perpendicular required.

CASE II. When the point is nearly opposite to the end of the line. Fig. 100.—1. To any point *m* in the line AB draw the line *Cm*. 2. Bisect the line *Cm*, or divide it into two equal parts, in the point *n*. 3. From *n*, with the radius *nm*, or *nG*, describe the arc *CGm*, cutting AB in *G*. 4. Through the point C, draw the line *CG*, and it will be the perpendicular required.

PROB. V. fig. 101. At a given point D, to make an angle equal to a given angle, ABC.—1. From the point B with any radius describe the arc *nm*, cutting the legs BA, BC, in the points *m*, *n*. 2. Draw the line DE, and from the point D, with the same radius as before, describe the arc *rs*. 3. Take the distance *mn* on the former arc, and apply it to the arc *rs*, from *r* to *s*. 4. Through the points *Ds* draw the line DF, and the angle EDF will be equal to the angle ABC, as was required.

PROB. VI. To draw a line parallel to a given line AB. Fig. 102, 103.

CASE I. When the parallel line is to pass through a given point C. Fig. 102.—1. To AB from the point C, draw any straight line *Cm*. 2. From the point *m*, with the radius *MC*, describe the arc *Cn* cutting AB in *n*. 3. And with the same radius, from the point C, describe the arc *mr*. 4. Take the distance *Cn*, and apply it to the arc *mr* from *m* to *r*. 5. Through the points *Cr*, draw the line *CGrH*, and it will be parallel to AB, as required.

CASE II. When the parallel line is to be at a given distance from AB. Fig. 103.—1. From any two points *r*, *s*, in the line AB, with a radius equal to the given distance, describe the arcs *n*, *m*. 2. Draw the line DG, to touch those arcs without cutting them, and it will be parallel to AB, as was required. N. B. The former case of this problem, as well as several other operations of practical geometry, may be more easily effected by a mathematical instrument known by the name of a parallel ruler.

PROB.

PROB. VII. fig. 104. To divide a given line AB, into any proposed number of equal parts.—1. From one end of the line A, draw Am , making any angle with AB; and from B the other end, draw Bn , making an equal angle ABn . 2. In each of the lines $A m$, Bn , beginning at A and B, set off as many equal parts, of any length, as AB is to be divided into. 3. Join the parts A 5, 14, 23, &c. and AB will be divided as required.

Note. Bn may be drawn parallel to Am by means of a parallel ruler.

PROB. VIII. fig. 105. To find the centre of a given circle, or one already described.—1. Draw any chord AB, and bisect it with the perpendicular CD. 2. Bisect CD in like manner with the chord EF, and their intersection O will be the centre required.

Note. The centre of a given circle, or any arch of it, may be found as in the next problem by taking three points in the circumference.

PROB. IX. fig. 106. To describe the circumference of a circle through three given points A, B, C.—1. From the middle point draw the lines or chords, BA and BC. 2. Bisect these chords perpendicularly with lines meeting each other in O. 3. From the point of intersection O, with the distance OA, OB, or OC, describe the circle ABC, and it will be that required.

PROB. X. fig. 107, 108. To draw a tangent to a given circle that shall pass through a given point A.

CASE I. When the point A is in the circumference of the circle. Fig 107.—1. From the given point A, to the centre of the circle, draw the radius OA. 2. Through the point A draw CD perpendicular to OA, and it will be the tangent required.

CASE II. When the point A is without the circle. Fig. 108.—1. To the point A from the centre O draw the line OA and bisect it in n . 2. From the point n with the radius nA or nO describe the semicircle ABO, cutting the given circle in B. 3. Through the points A, B, draw the line BA, and it will be the tangent required.

PROB. XI. fig. 109. To find a third proportional to two given lines A, B.—1. From the point C, draw two right lines, making any angle FCG. 2. In these lines take CE equal to the first term A, and CG, CD, each equal to the second term B. 3. Join ED, and draw GF parallel to it, and CF will be the third proportional required. That is, $CE(A) : CG(B) :: CD(B) : CF$.

PROB. XII. fig. 110. To find a fourth proportional to three given right lines A, B, C.—1. From the point D, draw two right lines, making any angle GDH. 2. In these lines, take DF, equal to the first term A, DE, equal to the second term B, and DH, equal to the third term C. 3. Join FE, and draw HG parallel to it, and DG will be the fourth proportional required. That is, $DF(A) : DE(B) :: DH(C) : DG$.

PROB. XIII. fig. 111. To find a mean proportional between two given right lines A, B.—1. Draw any right line in which take CE equal to A, and ED equal to B. 2. Bisect CD in O, and with OD, or OC, as a radius, describe the semicircle CFD. 3. From the given point E, draw EF perpendicular to CD, and it will be the mean proportional required. That is, $CE(A) : EF :: EF : ED(B)$.

PROB. XIV. fig. 112. To divide a given line AB, in the same proportion with which another given line C is divided.—1. From the point A draw AD equal to the given line C, and making any angle with AB. 2. To AD apply the several divisions of C, and join DB. 3. Draw the several lines 44, 33, &c. each parallel to DB, and the line AB will be divided as required.—That is, the parts A 1, 12, 23, 34, 4 B, on the line AB, will be proportional to the parts 10, 12, 23, 34, 45 on the line C.

PROB. XV. fig. 113. To make a triangle whose three sides shall be respectively equal to three given lines A, B, C.—1. Draw a line DE equal to one of the given lines C. 2. On the point D, with a radius equal to B, describe an arc. 3. And on the point E, with a radius equal to A, describe another arc, cutting the former in F. 4. Draw the lines DF, EF, and DFE will be the triangle required.

COR. Hence it is evident how an equilateral triangle may be described upon a given straight line.

Note. The three given lines must be of such a length that any two of them must be together greater than the third.

PROB. XVI. fig. 114. Upon a given line AB to describe a square.—1. From the point B, draw BC perpendicular, and equal,

to AB. 2. On A and C, with the radius AB, describe two arcs cutting each other in D. 3. Draw the lines AD, CD, and the figure ABCD will be the square required.

PROB. XVII. fig. 115. To describe a rectangle whose length and breadth shall be equal to two given lines AB and C.—1. At the point B, in the given line AB, erect the perpendicular BD, and make it equal to C. 2. From the points D, A, with the radii AB and C, describe two arcs cutting each other in E. 3. Join EA and ED, and ABDE will be the rectangle required.

PROB. XVIII. fig. 116. In a given triangle ABC to inscribe a circle.—1. Bisect the angles at A and B by the straight lines AO and BO. 2. From the point of intersection O, let fall the perpendicular On, and it will be the radius of the circle required.

PROB. XIX. fig. 117. About a given triangle ABC, to circumscribe a circle.—1. Bisect the two sides AB, BC, by the perpendiculars mo and no . 2. From the point of intersection o , with the distance OA, OB, or OC, describe the circle ACB, and it will be that required.

PROB. XX. fig. 118. To make a figure similar to a given figure ABCDE.—1. Take A b equal to the side of the figure required, and from the angle A draw the diagonals AC, AD. 2. From the points b, c, d , draw bc, cd, de , parallel to BC, CD, DE, and A $b c d e$ will be similar to ABCDE. The same thing may also be done by making the angles b, c, d, e , respectively equal to the angles B, C, D, E.

PROB. XXI. fig. 119. To construct a scale of chords to any given radius, AB.—1. Draw AC perpendicular to AB, and on A as a centre, with the given radius AB, describe the arc BC, which will be a quadrant. 2. On B, as a centre, with the given radius AB, describe an arc cutting the quadrantal arc at D, then BD will be an arc of 60 degrees. 3. Take an arc DE equal to DC, thus the quadrant BC will be divided into three equal arcs, each containing 30°. 4. Let each of the arcs BE, ED, DC, be divided into 30 equal parts, (which must be done by trials, for it cannot be done by any direct geometrical method,) and thus the whole quadrant will be divided into 90°. 5. Join BC, and on B, as a centre, with the distances between B and each of the divisions as radii, let arcs be described to meet BC, as in the figure. Thus the distance, between B and any one of the divisions of the scale BC, will be equal to the chord of the corresponding arc of the quadrant BEDC.

PROB. XXII. fig. 120. To make an angle of any proposed number of degrees.—1. Take the first 60 degrees from the scale of chords, and from the point A, with this radius, describe an arch nm . 2. Take the chord of the proposed number of degrees from the same scale, and apply it from n to m . 3. From the point A draw the lines A n and A m , and they will form the angle required. 4. If the given angle be greater than 90°, it may be taken at twice.

PROB. XXIII. fig. 120. An angle, BAC, being given to find the number of degrees it contains.—1. From the angular point A with the chord of 60 degrees describe the arc nm cutting the legs in the points n and m . 2. Take the distance nm , and apply it to the scale of chords, and it will shew the degrees required. 3. When the distance nm is greater than 90°, it must be taken at twice.

Note. Both this and the last problem may be performed by means of a protractor, which is a graduated arc designed for the purpose. See fig. 121.

PROB. XXIV. fig. 122. In a given circle, to describe a polygon of any proposed number of sides.—1. Divide 360° by the number of sides, and make an angle ACB, at the centre, whose measure shall be equal to the degrees in the quotient. 2. Join the points A, B, and apply the chord AB, to the circumference the given number of times, and it will form the polygon required.

PROB. XXV. fig. 122. On a given line AB to form a regular polygon of any proposed number of sides.—1. Divide 360° by the number of sides, and subtract the quotient from 180 degrees. 2. Make the angles ABC and BAC each equal to half the difference last found. 3. From the point of intersection C, with the distance CA, or CB, describe a circle. 4. Apply a chord, AD, to the circumference the proposed number of times, and it will form the polygon required.

Note. By this method the circumference of a circle may be divided into any number of equal parts.

GEOMETRY, SPHERIC. See PROJECTION OF THE SPHERE.

GEORGE LEWIS I. king of Great Britain, was the son of Ernest Augustus, elector of Hanover, by Sophia, daughter of Frederick, elector Palatine, and the grand-daughter of James I. of England. He was born in 1660, created duke of Cambridge in 1706, and succeeded queen Anne in 1714. The next year a rebellion broke out in Scotland in favour of the pretender, which was soon suppressed. In his reign parliaments were made septennial, and the order of the Bath revived. In 1720 happened the failure of the famous South-sea scheme, by which thousands of families were ruined. He died suddenly, June 11, 1727, at Osnaburgh.

GEORGE AUGUSTUS II. was born in 1683. He married, in 1705, princess Caroline, of Brandenburg-Anspach, who died in 1737. In 1714 he came to England with his father, whom he succeeded in 1727. In 1739 admiral Vernon was sent with a squadron to the West Indies, where he demolished Porto Bello, but failed in his attempt on Carthagena. In 1743 the king headed his army on the continent, and gained the battle of Dettingen. In 1745 the pretender's eldest son landed in the Highland, and was joined by several clans. After obtaining various successes, the rebels were defeated by the duke of Cumberland at Culloden in 1746. In 1748 peace was concluded at Aix-la-Chapelle. In 1755 war broke out between England and France, and in 1758 a treaty was entered into between England and Prussia. The French power was nearly destroyed in the East Indies. In America Louisburg was taken, and the capture of Quebec was followed by the conquest of Canada. The island of Guadaloupe and the settlement of Senegal were taken by the English. Admiral Hawke defeated the French fleet under Conflans, and the British flag waved triumphant in every part of the world. Amid this blaze of glory George II. died suddenly, by the bursting of the right ventricle of the heart, October 25, 1760.

GEORGE ST. THE CAPPADOCIAN, bishop of Alexandria on the expulsion of St. Athanasius. He was a native of Epiphania in Cilicia, and was, for some time, a purveyor in the army, but his frauds were so great that he was obliged to fly to avoid justice. He then went to Alexandria, where he displayed great zeal for Arianism, and in 356 was elected bishop by the prevailing party. His conduct was so cruel and oppressive that the people put him to death in 362. Great difficulties have been raised about this saint or hero. His very existence has been called in question. However the above is generally received. He is famous throughout all the East, and is called by the Greeks *Μεγαλομάρτυρ ὁ ἁγίου* the great martyr. England and Portugal have both chosen him for their patron saint.

GEORGE, FORT ST. a town and fort on the coast of Coromandel, in India. See MADRAS. Lat. 13°. 4'. 54". N. Lon. 80°. 24'. 49". E.

GEORGE, ST. in geography, one of the Azores. Lon. 28. 0. W. Lat. 38. 53. N.

GEORGE, ST. CROSS OF, a red cross in a field argent, which makes part of the British standard.

GEORGE, ST. DEL MINA, a fort on the Gold Coast of Guinea, the principal settlement of the Dutch in those parts, who took it from the Portuguese in 1630. It is about 10 miles W. of Cape Coast Castle. Lon. 0. 22. W. Lat. 5. 0. N.

GEORGE, ST. KNIGHTS OF. See GARTER. There have been various orders under this denomination, most of which are now extinct.

GEORGE, ST. RELIGIOUS OF. Of these there are divers orders and congregations; particularly canons regular of St. George in Alga, at Venice, founded by Bartholomew Colonna, in 1396, and established by Pope Boniface IX. in 1404. Pope Pius V. in 1570, gave these canons precedence of all other religious. There is another congregation in Sicily.

GEORGE THE III^d'S ISLAND, KING, the name given by Capt. Cook to Otaheite.

GEORGE'S BANK, ST. a fishing-bank of Massachusetts, on the Atlantic, E. of Cape Cod; extending between Lon. 67. 50. and 68. 40. W. and from Lat. 41. 15. to 42. 22. N.

GEORGE'S CHANNEL, ST. the channel between the W. coast of England and the S. E. of Ireland.

GEORGE'S ISLAND, ST. an island of England, in Cornwall, opposite to E. and W. Loe.

GEORGE'S ISLANDS, ST. islands in the Gulf of Mexico, on the coast of E. Florida, nearly opposite to the mouth of the Apalachicola. Lon. 84. 50. W. Lat. 29. 30. N.

VOL II.—NO. 96.

GEORGE'S RIVER, ST. a river of the United States, in the district of Maine, which becomes an arm of the sea, 2 leagues S. W. of Penobscott Bay.

GEORGE'S RIVER, ST. a very broad but short river of Maryland, in St. Mary's county.

GEORGE'S, ST. the largest of the Bermuda Islands, lying 500 miles E. of the continent of N. America. Lon. 63. 30. W. Lat. 32. 45. N.

GEORGE'S, ST. the capital of the island of Grenada, formerly called Fort Royal, from its fort.

GEORGETOWN, a large maritime district of S. Carolina, bounded on the N. E. by N. Carolina, S. E. by the Atlantic, S. W. by the Santee and N. W. by Camden and Cheraws districts. It is 112 miles long from N. to S. and 63 broad; and contains four counties, viz. Liberty, Winyaw, Kingston, and Williamsburg. It produces rice, Indian corn, cotton, indigo, wood, &c.

GEORGETOWN, the capital of the above district, 53 miles N. by E. of Charlestown.

GEORGETOWN, a town of Delaware, capital of Sussex county, 16 miles W. S. W. of Lewistown, and 103 S. of Philadelphia.

GEORGETOWN, a flourishing town of Georgia, 55 miles from Augusta.

GEORGETOWN, a town of Kentucky, 14 miles N. N. W. of Lexington, and 20 E. by N. of Frankfort.

GEORGIA, a country of Asia, bounded on the N. by Circassia, on the E. by Daghestan and Shirvan, on the S. by Armenia, and on the W. by the Euxine or Black Sea; comprehending the greatest part of the ancient Colchis, Iberia, and Albania. About the etymology of the name, authors differ. The most probable opinion is, that it is a corruption by the softening of Kurgia, from the river Kur; whence also it is supposed that the inhabitants are called by the Persians indifferently Gurgi and Kurgi; and the country Kurgistan and Gurgistan. Georgia is divided by a ridge of mountains into eastern and western; the former of which is again subdivided into the kingdoms of Caket, Carduel or Carthuel, and Goguetia; and the latter into the provinces of Abcassia, Mireta or Imeritia, and Guriel. Another division is into Georgia Proper, Abcassia, and Mingrelia. Teflis is the capital. This whole country is so extremely beautiful that some fanciful travellers have imagined they had here found the situation of the original garden of Eden. The hills are covered with forests of oak, ash, beech, chesnuts, walnuts, and elms, encircled with vines, growing perfectly wild, but producing vast quantities of grapes. From these is annually made as much wine as is necessary for the yearly consumption; the remainder are left to rot on the vines. The wine is so rich, that the Persian monarch has it always at his table. The whole country is very fertile, and abounds with cattle and wild fowls of various kinds. The bread is excellent, and the fruits, apples, pears, pomegranates, &c. have an exquisite flavour. Cotton grows spontaneously, as well as the finest European fruit-trees. Rice, wheat, millet, hemp, and flax, are raised on the plains, almost without culture. The valleys afford the finest pasturage: the rivers are full of fish; the mountains abound in minerals, and the climate is delicious; so that nature appears to have lavished on this favoured country every production that can contribute to the happiness of its inhabitants. The government of Georgia is despotic; but, were it not for the assistance of the Russian troops, the prince would frequently be unable to carry his decrees into execution. The punishments in criminal cases are shockingly cruel; fortunately they are not frequent, because it is easy to escape into some of the neighbouring countries, and because the prince is more enriched by confiscating the property of the criminal, than by putting him to torture. Judicial combats are considered as the privilege of nobility, and take place when the cause is extremely intricate, or when the power and interest of two claimants are so equal, that neither can force a decision of the court in his favour. This mode of trial is called an appeal to the judgement of God. This country formerly abounded with great cities, as appears from the ruins of many of them still visible, which shew that they must have been very large, opulent, and magnificently built. These were all destroyed by the northern barbarians from mount Caucasus, as the Alans, Huns, Suevi, and others, so much noted in history for their strength, courage, and conquests. In the fifteenth century, a king of Georgia divided among his five sons the provinces of Carduel and Caket, Imeritia, Mingrelia, Guriel, and Abcassia. These petty princes were too

jealous to unite for their common defence, and too weak singly to resist a foreign enemy, or even to check the encroachments of their great vassals, who soon became independent. By forming a party among these nobles, the Turks gradually gained possession of all the western provinces, while the Persians occupied the governments of Carduel and Caker. Since that period the many unsuccessful attempts of the Georgians to recover their liberty have repeatedly produced the devastation of their country. "The inhabitants, (says Sir George Chardin,) are robust, valiant, and of a jovial temper; great lovers of wine, and esteemed very trusty and faithful; endowed with good natural parts, but, for want of education, very vicious. The women are generally so fair and comely, that the wives and concubines of the king of Persia and his court are for the most part Georgian women. The Georgians are Christians of the Greek communion. Their dress nearly resembles that of the Cossacks; but men of rank frequently wear the habit of Persia. They usually dye their hair, beard, and nails, with red. The Georgian women employ the same colour to stain the palms of their hands. On their heads they wear a cap or fillet, under which their black hair falls on their forehead: behind, it is braided into several tresses. Their eyebrows are painted with black, so as to form one entire line, and their faces are perfectly coated with white and red.

GEORGIA, the most southern of the United States of America, bounded on the E. by the Atlantic Ocean, on the S. by E. and W. Florida, on the W. by the Mississippi, and on the N. E. and N. by S. Carolina and Tennessee. It is 666 miles long and 262 broad, lying between 80° and 91° Lon. W.; and 30° 17' and 35° Lat. N. The winters in Georgia are very mild and pleasant. Snow is seldom or never seen. The soil and its fertility are various, according to situation and improvements. By culture are produced rice, indigo, cotton, silk, Indian corn, potatoes, oranges, figs, pomegranates, &c. Rice at present is the staple commodity; but great attention is also paid to the raising of tobacco. Georgia, before the revolution, was divided into parishes; afterwards into three districts, but now into two, called the Upper and Lower; which are subdivided into twenty-four counties; nine in the Lower District, viz. Camden, Glynn, Liberty, Chatham, Bryan, McIntosh, Effingham, Scriven, and Burke; and fifteen in the Upper, viz. Montgomery, Washington, Hancock, Greene, Franklin, Oglethorpe, Elbert, Wilkes, Lincoln, Warren, Jefferson, Jackson, Bullock, Columbia, and Richmond. The chief towns are Savannah, the former capital of the state; Augusta, the late seat of government, Louisville, the present metropolis; (see these articles); Sunbury, Brunswick, Frederica, Washington, St. Patricks, Golinton, Greensborough, &c. The whole coast of Georgia is bordered with islands, the principal of which are Skiddaway, Wassaw, Ossabaw, St. Catherines, Sapelo, Frederica, Jekyll and Cumberland. Near Augusta, there is a bank of oyster-shells ninety miles from the sea; and in Wilkes county, near Washington, there is a remarkable spring which rises from a hollow tree, five feet long. The inside of the tree is covered with a coat of matter an inch thick, and the leaves around the spring are incrustated with a peculiar substance as white as snow. The water is said to be an effectual remedy for the scurvy, scrofula, gout, rheumatism, and consumption. The chief rivers in this state are the Savannah, Turtle river, Little and Great Satilla, Crooked river, and St. Mary's which forms a part of the southern boundary of the United States. The rivers in the middle and western parts are the Apalachicola, formed by the Chatahouchee and Flint rivers, Mobile, Pascagoula, and Pearl rivers. All these run southward into the Gulf of Mexico.

GEORGIA, South, an island of the S. Pacific Ocean, discovered and named by Captain Cook in 1775. Lon. between 38. 13. and 35. 34. W. Lat. 53. 57. and 54. 57. S.

GEORGICS, [*γεωργικόν*, *georgiques*, Fr.] poetical compositions upon husbandry. Hesiod and Virgil are the two greatest masters in Georgics. The moderns have produced nothing in this kind, except Rapin's book of Gardening; and the celebrated poem entitled Cyder, by Mr. Philips, who, if he had enjoyed the advantage of Virgil's language, would have been second to Virgil in a much nearer degree.

GEORGIEV, a town of Russia, in the government of Caucasus, thirty-two miles W. N. W. of Ekaterinograd.

GEORGINA, in botany, a genus of the syngenesia superflua

class and order. Receptacle chaffy; no down; calyx double; the outer many-leaved; inner one-leaved, eight-parted. There are three species.

GEORGITZ, a town of Wallachia, eighteen miles N. N. E. of Bucharest, and twenty-four S. E. of Tergovisto.

GEORGIUM SIDUS, or the GEORGIAN PLANET. See ASTRONOMY.

GEOSCOPY, [from *γη*, earth, and *σκοπεω*, to view,] an observation of the different qualities of the earth.

GEPIDÆ, GEPIDES, or GEPID, in ancient geography, according to Procopius, were a Gothic people, some of whom, in the migration of the Goths, settled in an island at the mouth of the Vistula, which they called Gepidos after their own name, which denotes lazy or slothful; others in Dacia, calling their settlement there Gepidia.

GEPPING, a town of Wirtemberg, twenty-five miles E. of Stutgard. Lon. 9. 45. E. Lat. 48. 44. N.

GERA, a town of Saxony in Misnia, on the Elster; thirty miles S. S. W. of Leipsic, and sixty-eight W. of Dresden.

GERAH, [גרה, Heb.] the smallest silver coin among the Hebrews, in value sevenpence-halfpenny sterling.

GERANITES, in natural history, an appellation given to such of the semi-pellucid gems as are marked with a spot resembling a crane's eye.

GERANIUM, CRANE'S-BILL, in botany, a genus of the monadelphia decandria class and order. Natural order, Grinales. Calyx five-leaved; corolla five-petaled, regular; nectary five-horned glands, fastened to the base of the longer filaments; fruit five-grained, beaked; beaks simple, naked, neither spiral nor bearded. There are thirty-two species. The common wild sorts, and those which are brought from the colder climates, are hardy enough, and require little care; but the African species, and the others from hot countries which make so very beautiful a figure in our greenhouses, require great care in their culture and propagation. These may be propagated by seed, which should be sown toward the end of March in beds of light earth, carefully shading them from the sun, and giving them frequent but gentle waterings, till they are well rooted. The shrubby African geraniums are commonly propagated by cuttings, which planted in a shady border, in June or July, will take good root in five or six weeks; and they may then be taken up and planted in separate pots, placing them in the shade till they have taken new root, after which they may be removed into a sheltered situation. Geranium is recommended as one of the greatest vulneraries and abstersgents of the vegetable world, and is highly extolled for its power of stopping profusion of the menses, and hemorrhages of all kinds. Experience confirms this, especially among the poor people in the country; and it were to be wished, that the plant could be brought into more esteem in the shops, where at present it is disregarded.

GERAR, or GERARA, in ancient geography, the south boundary of Canaan near Beersheba; situated between Cades and Zur; two deserts, the one facing Egypt and the other Arabia Petraea.

GERARD, ALEXANDER, D. D. professor of divinity in King's college, Aberdeen, and one of his majesty's chaplains for Scotland. He was eldest son of the Rev. Gilbert Gerard, and was born the 22d Feb. 1728. He studied theology at the universities of Aberdeen and Edinburgh, was chosen assistant to professor D. Fordyce, in 1750, and was afterwards appointed his successor, upon his untimely death, in 1752. In 1754, a material alteration being made in the order of teaching philosophy in the university, professor Gerard was appointed to lay before the public the reasons which had influenced them to deviate from the former practice; which he accordingly did in a small pamphlet, that gave universal satisfaction; wherein he pointed out the inconveniences of the old, and the advantages of the new, plan; which was at this time adopted by both colleges. About this time too he was an active member of a respectable literary society, which met once a fortnight at Aberdeen, and of which Drs. Blackwell, Beattie, Gregory, Reid, Campbell, and other eminent literary gentlemen were members. On the 5th of Sept. 1759, he was ordained a minister of the church of Scotland; on the 11th of June, 1760, he was appointed professor of divinity in the Marischal college, and minister of the Grayfriars church at Aberdeen; and about the same time he was created D. D. Dr. Gerard's character in private life was amiable and exemplary. Kindness to his relations, affability with his dependants

GERMANY

Map showing the geographical layout of Germany and surrounding regions, including labels for major cities, rivers, and neighboring countries. The map includes a grid of latitude and longitude coordinates.

Major cities labeled include: Berlin, Warsaw, Prague, Vienna, and others. Rivers shown include the Rhine, Danube, and others. Neighboring countries shown include France, Poland, and others.

Geographical features include the North Sea, Baltic Sea, and various mountain ranges.

Latitude and longitude coordinates are marked along the edges of the map.

ants, steadiness and warmth in his attachments to his friends, and hospitality to strangers without extravagance or ostentation, were conspicuous in his general conduct. His public discourses, as a minister and professor, were equally marked by distinctness of arrangement, accuracy of composition, and justness of reasoning. His friend, Dr. Beattie, (who himself stands high in the republic of letters) assures us, that "he had improved his memory to such a degree, that, in little more than an hour, he could get by heart any sermon of ordinary length; though far from availing himself of this talent, as many would have done, he composed with care all the sermons that he preached." He was author of, 1. An Essay on Taste: 8vo. 1759. 2. Dissertations on Subjects relating to the Genius and Evidences of Christianity: 8vo. 1766. 3. An Essay on Genius: 8vo. 1774. 4. Several Sermons on Various Subjects, published from 1760 to 1782; and 5. A part of his Theological Course, entitled "The Pastoral Care, published in 1799, by his son, Dr. Gilbert Gerard, who succeeded him in his professorship. His Essay on Taste gained the gold prize medal given by the Philosophical Society of Edinburgh in 1756.

GERARD, TUNG, or TOM, founder and first Grand Master of the Knights hospitaliers of St. John, or Knights of Malta, was born at Amalfi, in Italy, in the eleventh century. In A. D. 1100, he assumed a religious habit, with a white cross on the breast, and, with many others, engaged in vows of chastity, poverty, and to relieve all Christians in distress, &c. He died in 1120, and was succeeded as grand master by Raymond du Puy.

GERARDE, JOHN, surgeon in London, the greatest botanist of his time, and many years chief gardener to lord Burleigh; who was himself a great lover of plants, and had the best collection in the kingdom, among which were many exotics introduced by Gerarde. In 1597, he published his Herbal, which was printed at the expence of J. Norton, who procured the figures from Frankfurt. In 1663, Thomas Johnson, an apothecary, published an improved edition of Gerarde's book; which met with such approbation by the university of Oxford, that they conferred upon him the degree of M. D. and it is still much esteemed. The descriptions in the herbal are plain and familiar; and are calculated to make the reader understand the characters of the plants.

GERARDIA, in botany, a genus of the angiospermia order, and didynamia class of plants; natural order, Personate. Calyx five-cleft; corolla two-lipped, lower lip three-parted, the lobes emarginate, the middle segments two-parted; capsule two-celled, gaping. There are ten species.

GERAW, GERAU, or GROSS, a town of Hesse Darmstadt, ten miles S. E. of Mentz.

GERBEROY, a town of France, in the department of Oise, and late province of Isle of France, six miles N. E. of Gournay, and fifty N. of Paris.

GERFALCON. See FALCO.

GERGESEI, or GERGESENES, one of the seven ancient nations of Canaan, less frequently mentioned than the rest. They appear to have been less considerable and more obscure: their name is from Girgasi, one of Canaan's sons.

GERGINSWALDE, a town of Saxony, in the circle of Leipzig, four miles N. E. of Rochlitz.

GERMAIN, or ST. GERMAIN, a town of France, in the department of Seine and Oise, and late province of the Isle of France, ten miles N. W. of Paris.

GERMAIN LAVAL, St. a town of France, in the department of Rhone and Loire, 18 miles S. of Roanne, and 225 S. E. of Paris. Lon. 4. 2. E. Lat. 45. 50. N.

GERMAINS, St. a borough of England, in Cornwall, ten miles W. of Plymouth.

GERMAN, in genealogy, signifies whole, entire, or own. Germani, quasi eadem stirpe geniti. Festus. Hence, Brother German, denotes a brother both by the father's and mother's side, in contradistinction to uterine brothers, &c. who are only so by the mother's side. And Cousins German, are those in the first degree, the children of brothers or sisters.

GERMAN PLATS, a town and township of New York, the capital of Herkemer county, eighty miles N. W. by W. of Albany.

GERMANDER, in botany. See TEUCRIUM.

GERMANICUS CÆSAR, CLAUDIUS, the son of Drusus, and nephew to the emperor Tiberius, who adopted him. By his mother Antonia, daughter of Mark Antony and Octavia, he was

grand-nephew to Augustus. He was much renowned as a general, but still more for his virtues. He took the title of Germanicus from his conquests in Germany; but though he refused the empire offered to him by his army, Tiberius, jealous of his success and popularity, caused him to be poisoned, A. D. 29, aged 34. He was a protector of learning; and composed some Greek comedies and Latin poems, some of which are still extant.

GERMANO, St. a town of Naples, at the foot of Mount Casano. Lon. 13. 59. E. Lat. 41. 13. N.

GERMANY, till very lately a powerful empire of Europe, but which, in different ages, has had very different limits. The name, according to the most probable conjecture, is derived from the Celtic words, *Ghar man*, signifying a warlike man, to which their other name, Allman, or Aleman, likewise alludes. The ancient history of the Germans is altogether wrapped up in obscurity; nor do we, for many ages, know any thing more of them than what we learn from the history of their wars with the Romans. The first time they are mentioned by the Roman historians, is about B. C. 211, when Marcellus subdued Insurbia and Liguria, and defeated the Gasatæ, a German nation situated on the banks of the Rhine. From this time history is silent with regard to all these northern nations till the eruption of the Cimbri and Teutones, who inhabited the most northerly parts of Germany. It is indeed very difficult to fix the limits of the country called Germany by the Romans. The southern Germans were intermixed with the Gauls, and the northern ones with the Scythians; and thus the ancient history of the Germans includes that of the Dacians, Huns, Goths, &c. till the destruction of the western Roman empire by them. Ancient Germany, therefore, we may reckon to have included the northern part of France, the Netherlands, Holland, Germany so called at present, Denmark, Prussia, Poland, Hungary, part of Turkey in Europe, and Muscovy. The Romans divided Germany into two regions; 1. Belgic, or Lower Germany, which lay to the southward of the Rhine; and 2. Germany Proper, or High Germany.

1. GERMANY, BELGIC, or LOWER GERMANY, lay between the rivers Seine and the Rhine; and in this we find a number of different nations, the most remarkable of which were the following: 1. The Ubii, whose territory lay between the Rhine and the Mosæ, (or Maese,) and whose capital was Cologne. 2. Next to them were the Tungri, supposed to be the same, whom Cæsar calls Eburones and Condrusi; and whose metropolis, then called Attuatica, has since been named Tongres. 3. Higher up from them, and on the other side of the Moselle, were the Treviri, whose capital was Augusta Trevirorum, now Triers. 4. Next to them were the Tribocci, Nemetes, and Vangiones. The former dwelt in Alsace, and had Argentoratum, now Strasburg, for their capital: the others inhabited the cities of Worms, Spire, and Mentz. 5. The Mediomatrici were situated along the Moselle, about the city of Mentz in Lorraine: and above them were situated another German nation, named Raurici, Rauraci, or Rauriaci, who inhabited that part of Helvetia, above Basil. To the W. and S. of these were the Nervi, Suevones, Silvanectes, Leuci, Rhemi, Lingones, &c. who inhabited Belgic Gaul. Between the heads of the Rhine and Danube were seated the ancient kingdom of Vindelicia, whose capital was called Augusta Vindelicorum, now Augsburg. Below it, on the banks of the Danube, were the kingdoms of Noricum and Pannonia. The first of these was divided into Noricum-Ripenses and Mediterraneum. It contained a great part of the present Austria, Styria, Carinthia, Tyrol, Bavaria, and some others of less note. The latter contained the kingdom of Hungary, divided into Upper and Lower; and extending from Illyricum to the Danube, and the mountains Cæti in the neighbourhood of Vindobona, now Vienna.

II. GERMANY, PROPER, UPPER, or HIGH GERMANY, lay beyond the Rhine and Danube. Between the Rhine and the Elbe were the following nations. 1. The Chævi, Upper and Lower: who were divided from each other by the river Visurgæ, now the Weser. Their country contained what is now called Bremen, Lunenburg, Friesland, and Groningen. The upper Chævi had the Cherusi, and the lower the Chamavi on the south-east, and the German Ocean on the north-west. 2. The Frisi, Upper and Lower, were divided from the lower Chævi by the river Amisia, now the Ems; and from one another by an arm of the Rhine. Their country still retains the name of Friesland, and is divided into

into East and West; but the latter has been long dismembered from Germany, as one of the seven United Provinces, and now forms the department of Ems in the French empire. 3. Beyond the Isela (now the Yssel), which bounded the country of the Frisii, were situated the Brueteri, who inhabited the tract now called Broecmorland; and the Mercii, about the river Lupe. On the other side of that river were the Usippii, or Uspites; but these were famed for often changing their territories, and therefore found in other places. 4. Next to these were the Juones, or inhabitants of Juliers, between the Maese and the Rhine. 5. The Catti, another ancient and warlike nation, inhabited Hesse and Thuringia, from the Haartzian mountains to the Rhine and Weser; among whom were comprehended the Mattiaci, whose capital is by some thought to be Marpurg, by others Baden. 6. Next to these were the Seducii bordering upon Suabia; Narisci, or the ancient inhabitants of Northgow, whose capital was Nuremberg; and the Marcomanni, whose country anciently reached from the Rhine to the head of the Danube and to the Neckar. The Marcomanni afterwards went and settled in Bohemia and Moravia, under their general or king Maroboduus: and some of them in Gaul, whence they drove the Boii, who had seated themselves there. 7. On the other side of the Danube, and between the Rhine and it, were the Hermunduri, who possessed the country now called Misnia in Upper Saxony; though some make their territories to have extended much farther, and to have reached to, or even beyond, Bohemia, then the seat of the Boii, whence its name. 8. Beyond them, on the north of the Danube, was another seat of the Marcomanni along the river Albis, or Elbe. 9. Next to Bohemia were situated the Quadi, whose territories extended from the Danube to Moravia, and the northern part of Austria. These are comprehended under the ancient name of Suevi; part of whom at length forced their way into Spain, and settled a kingdom there. 10. Eastward of the Quadi were situated the Bastarnæ, and parted from them by the Grauna, now Gran, a river that falls into the Danubé; and by the Carpathian mountains, from them called Alpes Bastarnicæ. The country of the Bastarnæ indeed made part of the European Sarmatia, and so was without the limits of Germany properly so called; but we find these people so often in league with the German nations, and joining them for the destruction of the Romans, that we cannot but account them as one people. Between those nations, seated along the other side of the Danube and the Hercynian forest, were several others whose exact situation is uncertain, viz. the Martigni, Buri, Borades, Lygii, or Logiones, and some others, who are placed by our geographers along the forest above-mentioned, between the Danube and the Vistula. On this side the Hercynian forest, were the famed Rætii (now Grisons), seated among the Alps. Their country, which was also called Western Illyricum, was divided into Rætia Prima, or Propria, and Secunda; and was then of much larger extent, spreading itself towards Suabia, Bavaria, and Austria. On the other side of the Hercynian forest were, 1. The Suevi, who spread themselves from the Vistula to the river Elbe. 2. The Longobardi, so called, according to some, on account of their wearing long beards; but according to others, on account of their consisting of two nations, viz. the Bardi and Lingones. These dwelt along the river Elbe, and bordered southward on the Chauci above-mentioned. 3. The Burgundi, of whose original seat we are uncertain. 4. The Semnones, who about the time of Tiberius, were seated on the river Elbe. 5. The Angles, Saxons, and Goths, were probably the descendants of the Cimbri, and inhabited the countries of Denmark, along the Baltic Sea, and the peninsula of Scandinavia, containing Norway, Sweden, and Finmark. 6. The Vandals were a Gothic nation, who, proceeding, from Scandinavia, settled in the countries now called Mecklenburgh and Brandenburg. 7. Of the same race were the Dacians, who settled themselves in the neighbourhood of Palus Mæotis, and extended their territories along the banks of the Danube. Germany contains mines of gold, silver, lead, tin, copper, iron, quicksilver, cinnabar, ochre, loadstone, coals, &c. with quarries of marble, alabaster, and various other stones. And in many places are found diamonds, rubies, emeralds, amethysts, cornellians, agates, as well as sulphur, alum, saltpetre, vitriol, &c. The German mines, though early explored, still continue great sources of wealth. Of quicksilver, one mine alone yields 50,000lb. weight a-year. They furnish the finest sort of clay for porcelain, and have excellent and extensive salt-works.

GERMANY, MODERN BOUNDARIES, EXTENT, AND DIVISIONS OF. Germany is bounded on the north by the German Ocean, Denmark, and the Baltic Sea; on the east by Prussia, Poland, and Hungary; on the south by Italy, Switzerland, and the Alps; and on the west by France and Batavia or Holland; the French now claiming the Rhine as their eastern boundary. Before the present war its western boundary was old France and the Netherlands, and its extent was estimated at 640 miles in length, and 550 in breadth. The German empire was formerly divided into ten circles, afterwards it consisted only of nine; viz. Upper, and Lower Saxony, Westphalia, Upper, and Lower Rhine, Franconia, Swabia, Bavaria, and Austria, which see. But owing to the late very great successes of the French over this part of Europe the Germanic constitution is now almost totally annihilated, the circles of Westphalia, Saxony, and Bavaria, and the duchy of Wirtemberg, having been erected into the dignity of kingdoms.

i. **GERMANY, HIGH**, comprehends the Palatinate of the Rhine, Franconia, Suabia, Bohemia, Moravia, Austria, Carinthia, Carniola, and Stiria: and formerly included Switzerland and the Grison's country.

ii. **GERMANY, LOW**, comprehends part of the Low Country of the Rhine, Cologne, and Mentz; Westphalia, Hesse, Brunswick, Misnia, Lusatia, Upper and Lower Saxony, Mecklenburg, Lunenburg, Brandenburg, and Pomerania. From the central situation of Germany, its commerce with the rest of Europe is very extensive. Its minerals are decidedly the first native articles for trade; after which are medicinal waters, salt, hemp, flax, linen, silk, wines, fruits, corn, cattle, stuffs, cloths, timber, porcelain, wrought iron and steel, drugs, oils and colours, are the principal. The French artisans, exiled by the revocation of the edict of Nantz, enabled Germany to stand in no need of the wrought silks of other countries. Great commercial fairs still exist in Germany. There are thirty-eight universities in Germany; nineteen Protestant, seventeen Catholic, and two which partake of both; besides a number of literary societies and academic institutions: and education in general is particularly attended to even in the very lowest ranks.

GERME, among shipping, a kind of bark used in the shallows on the coast of Egypt, as drawing but little water. They are strong and well built, but have no decks.

GERMEN, the SEED-BUD. See BOTANY.

GERMEN, by Pliny and the ancient botanists is used to signify a bud containing the rudiments of the leaves.

GERMINATION, among botanists, comprehends the precise time which seeds take to rise after they have been committed to the soil. The different species of seeds are longer or shorter in rising, according to the degree of heat which is proper to each. Millet, wheat, and several of the grasses, rise in one day; blite, spinach, beans, mustard, kidney-beans, turnips, and rocket, in three days; lettuce and dill, in four; cucumber, gourd, melon, and cress, in five; radish and beet, in six; barley, in seven; orach, in eight; purslane, in nine; cabbage, in ten; hyssop, in thirty; parsley, in forty or fifty days; peach, almond, walnut, chesnut, pæony, horned poppy, hyecoum, and ranunculus falcatus, in one year; rose-bush, cornel-tree, hawthorn, medlar, and hazel-nut, in two. The seeds of some species of orchis, and of some liliaceous plants never rise at all. Some seeds require to be sowed almost as soon as they are ripe, otherwise they will not sprout or germinate. Of this kind are the seeds of coffee and fraxinella. Others, particularly those of the pea-bloom flowers, preserve their germinating faculty for a series of years. Mr. Adanson asserts, that the sensitive plant retains that virtue for thirty or forty years. Air and water are the agents of germination. The humidity of the air alone makes several seeds to rise that are exposed to it. Seeds too are observed to rise in water, without the intervention of earth; but water without air is insufficient. Mr. Homberg's experiments on this head are decisive. He puts several seeds under the exhausted receiver of an air-pump, with a view to establish something certain on the causes of germination. Some of them did not rise at all; and the greatest part of those which did, made very weak and feeble productions. Thus it is for want of air that seeds, which are buried at a very great depth in the earth, either thrive but indifferently, or do not rise at all. They frequently preserve, however, their germinating virtue for many years within the bowels of the earth; and it is not unusual, upon a piece of ground being newly dug to a considerable depth, to observe it soon after covered with several plants, which had not been seen

seen there in the memory of man. Were this frequently repeated, it would doubtless be the means of recovering certain species of plants which are regarded as lost; or which perhaps have never come to the knowledge of botanists. Some seeds require a greater quantity of air than others. Thus purslane which does not rise till after lettuce in the free air, rises before it in vacuo; and both prosper but little, or perish altogether, while cresses vegetate as freely as in the open air. The late discoveries in chemistry, have thrown much light on this subject. In 1793, M. Humboldt discovered, that simple metallic substances are not favourable to the germination of plants, but that metallic oxides favour it in proportion to their degree of oxidation. This led him to search for a substance with which oxygen might be so weakly combined as to be easily separated, and he tried oxygenated muriatic acid gas mixed with water. Cresses in this acid shewed germs at the end of six hours, and in common water at the end of thirty-two hours. The action of the acid on vegetable fibres was announced by a great number of air-bubbles covering the seeds, which did not take place with water till the end of fifty or forty-five minutes. These experiments, published in Humboldt's "Flora Subterranea Fribergensis," and in his "Aphorisms on the Chemical Physiology of Plants," have been repeated by Messrs. Uslar, Plenck, Villdenow, and others. See "Dictionnaire de Physique, par Gehler." They were made at a temperature of from twelve to fifteen of Reaumur. In 1796, Humboldt made some new experiments, and found that, by joining caloric to oxygen, vegetation was still more accelerated. He threw equal quantities of the seeds of garden-cresses into pure water and oxygenated muriatic acid, at a temperature of 58° F. Cresses germinated in the acid in three hours, but in the water not till the end of twenty-six hours. In the muriatic, nitric, or sulphuric acid, there was no germ at all: though according to the experiments of M. Candolle, the nitric acid accelerates germination also, when greatly diluted with water. Professor Pohl at Dresden caused the seed of a new species of Euphorbia to germinate in oxygenated muriatic acid, though taken from Bocconi's collection of dried plants, 110 or 120 years old. Jacquin and Vander Schort at Vienna threw into oxygenated muriatic acid all the old seeds, which had been kept twenty or thirty years at the botanical garden, every attempt to produce vegetation in which had proved fruitless, and the greater part of them, even the hardest seeds, germinated. Among these were the yellow bonduc, or nickar-tree, the pigeon-pea, the *Dodonaea Angustifolia*, the climbing mimosa, and some new species of *Hopaea*. There are now shewn at Vienna very valuable plants, which are entirely raised by the oxygenated muriatic acid, and are from five to eight inches high. Humboldt made the *elusia rosea* to germinate, the seeds of which had been brought from the Bahama islands by Boose, and had resisted every previous effort to make them vegetate. For this purpose he used a new process, which will be easier for gardeners who cannot procure the oxygenated muriatic acid. He formed a paste by mixing the seeds with the black oxide of manganese, and then poured over it the muriatic acid diluted with water, in the proportion of half a cubic inch of the acid to three of water. The vessel containing this mixture must be covered, but not shut close, lest it should burst. At the temperature of 93°, the muriatic acid becomes strongly oxidated, the oxygenated muriatic gas which is disengaged passes through the seeds; and during this passage the irritation of the vegetable fibres takes place. Philos. Mag.

GERNOI, a fort of Russian Siberia, in Kolivan.
GERON, or **GERON POINT**, a cape of Ireland, in Antrim county, 15 miles N. E. of Antrim, and 32 N. of Belfast.

GERONA, **GIRONA**, or **GIRONNA**, an ancient town of Spain, in Catalonia, 47 miles N. E. of Barcelona. Lon. 2. 52. E. Lat. 42. 10. N.

GERONTES, [from *geron*,] in antiquity, a kind of judges, or magistrates, in ancient Sparta, answering to what the Areopagites were at Athens. See **AREOPAGUS**.

GEROPOGON, in botany, a genus of the polygamia aequalis order, and syngenesia class of plants; natural order, Compositæ. Calyx simple; receptacle with bristle-shaped chaffs; seeds of the disk with a feathered down of the ray, with five awns. There are three species.

GERRI, a town of Nubia, on the Nile, 130 miles N. N. E. of Senaar. Lon. 30. 34. E. Lat. 16. 15. N.
 VOL. II.—NO. 96.

TERS, a department of France, bounded on the N. by those of Landes, and Lot and Garonne. Auch is the capital.

GERSPACH, a town of Suabia, on the Murg, 2 miles S. E. of Baden.

GERTRUDENBURG, **GERTRUYDENBERG**, or **GERTRUYDENBURG**, an ancient and strong town of Batavia or Holland, in the department of Dommel and Scheldt, and late province of Dutch Brabant. It lies 7 miles N. E. of Breda.

GERUND, [*gerundium*, Latin,] in the Latin grammar, a kind of verbal noun, which governs cases like a verb.

GERUNDS are substantive nouns of the second declension and neuter-gender, partaking of the nature of a participle, declinable only in the singular number, through all the cases except the vocative, as *legendum*, *legendi*, &c. They express not only the time, but the manner, of an action; as, "he fell *in running* post." They differ from participles, in that they express the time, which participles do not, though they always imply some time; and they differ from tenses properly so called, in that they express the manner, which the tenses do not.

GERUNDA, in ancient geography, a town of the Ausetani, in Hispania Citerior, on the S. or right side of the Sambroca; now called Gerona.

GERYON, or **GERYONES**, in fabulous history, a king of Gades, in Iberia, who had three bodies, and fed his cattle with human flesh. This monster was slain by Hercules, who carried off his cattle.

GESNER, **SOLOMON**, the celebrated author of the "Death of Abel," was the son of John Conrad Gesner, bookseller and member of the Great Council, and was born at Zurich in 1730. In his early years he shewed no signs of superior abilities; and his progress in education was so slow, that his master gave him up as incapable of any greater attainments than writing and the four first rules of arithmetic. Upon this he was placed under a clergyman, a relation of his father's, who shewed himself better acquainted with the art of discovering the natural inclinations of his pupils. He often carried young Gesner with him into the fields, to survey the beauties of nature; and finding that he took pleasure in such lessons, and listened to them with peculiar attention, he repeated some of the most striking passages of ancient authors, who have written on these subjects, in the most agreeable manner. By this ingenious artifice, young Gesner's mind began to open, and its powers to expand; and it is, perhaps, owing to this circumstance, that he became so fond of the language of Virgil and Theocritus. When he arrived at a proper age, he chose his father's profession. Of five printing-houses at Zurich, two were occupied by Gesners. The house in which our poet's father had a share, was known by the firm of Orel, Gesner, and Company, and was famed for the elegance of the works which it published. But Mr. Gesner did not damp his genius, by the drudgery of business. He indulged himself freely in pursuing his favourite object, and his partners never grudged him that time which he devoted to study. In 1752, he made a tour through Germany, not so much to extend his commerce, as to see and be acquainted with those authors who have done honour to their country. The following anecdote is strikingly characteristic of that timidity which often accompanies true genius. When Mr. Gesner was at Berlin, he was admitted into a literary society, of which Gleim and Lessing were members. Every member read in turn some pieces of his own composition, and Gesner was very desirous of submitting to these able critics a small work, which was his first attempt. As each member had done reading, Gesner was observed to move his hand with a kind of tremor towards his pocket, and to draw it back again without producing any thing. Having not yet published any work, none of the company could guess the cause of a motion which his modesty prevented him from explaining. The piece which he wished, but had not the courage, to shew, was his poem, entitled "Night," which he published on his return to Zurich in 1753. It was considered as an original, of which no model is to be found among the moderns; but in Gesner's opinion, it was only a piece of imaginary painting, or, to use his own words, in one of his letters to Mr. Huber who translated his works, "a caricature composed in the moments of folly or intoxication." In this little poem he has introduced a short episode on the origin of the glow-worm, containing a poetical explanation of this natural phosphorus, which has all the beauty of Ovid's *Metamorphoses* without their prolixity.

lixity. The success of this essay emboldened him to publish a pastoral romance, called "Daphnis," in three cantos. The applause deservedly bestowed upon this performance induced him to publish his "Idylls," and other rural poems in imitation of Theocritus. Pastoral poetry, which was then little known in Germany but by translations, began to be preferred to every other kind. His "Death of Abel," was first published in 1758. It is written, like the rest of his pieces, in poetical prose; and went through three editions in one year. The French edition was followed by others, in Italian, Dutch, Danish, and, lastly, two in English, one in prose and the other in verse. He next published his "First Navigator," a poem in three cantos, which many consider as his masterpiece. He produced likewise, in the dramatic stile "Evander and Alcimne," in three acts; and "Erastus," in one act, which was represented with applause at Leipsic and Vienna. In 1765 he published ten landscapes, engraved by himself from his own designs. These were followed by others. He was also the author of a Letter on Landscape Painting, Poems, &c. He died in 1781.

GESNERIA, in botany, a genus of the angiospermia order, and didynamia class of plants; natural order, Personate. Calyx five-cleft, sitting on the germ; corolla incurved and recurved; capsule inferior, two-celled. There are twelve species.

GESTRICIA, or **GESTRICKLAND**, a province of Sweden, bounded by Helsingia on the N. by the gulf of Bothnia on the E. by Upland, Westmanland, and Dalecarlia, on the S. and by Dalecarlia on the W. It abounds with mines, forests, lakes, and rivers; and is 17 miles long and 10 broad. Gefle is the capital. The Dahl, the finest river in Sweden, meanders through it.

GESTURE, in rhetoric, consists principally in the action of the hands and face; and may be defined, a suitable conformity of the motions of the countenance, and of several parts of the body, in speaking to the subject of discourse. See **ORATORY**.

GETÆ, an ancient nation of Thrace, who dwelt on both sides of the Ister, near Scythia, supposed to be the ancestors of the Dacians and Goths; or according to others, of the Walachians or Moldavians.

GE-TCHAO, a town of China, in the province of Chang-tong, 27 miles E. S. E. of Lu.

GETHSEME, [גֶּתְשֶׁמֶנִּי, Heb. *i. e.* the valley of fat, or fertility,] in ancient geography, a village at the foot of Mount Olivet, whither Jesus Christ sometimes retired in the night-time. It was in a garden belonging to this village that he suffered the agony in which he sweated blood; and was arrested by Judas and his band. The place is described by Maundrel as an even plot of ground, not above 57 yards square, lying between the foot of Mount Olivet and the brook Cedron.

GETHYLLIS, in botany, a genus of the monogynia order, and diodecandria class of plants; natural order, Spathaceæ. Calyx none; corolla six-parted; berry club-shaped, radicle, one-celled. There are four species.

GEUM, **AVENS**, or **HERB BENNET**, a genus of the polygamia order, and icosaandria class of plants: natural order, Senticosæ. Calyx ten-cleft; petals five; seeds with a kneed awn. There are nine species, natives of Europe and North America.

GEX, a late territory of France, in the province of Bresse; bounded by Mount Jura, the Rhone, the lake of Geneva, and Switzerland. It now forms the department of Ain.

GEX, a town of France, in the department of Ain, 10 miles N. N. W. of Geneva.

GEZIRA, a town of Asiatic Turkey, in the province of Diarbekir, 70 miles N. W. of Mousul.

GEZULA, or **GAZULA**, a country of Africa, S. of Morocco, the inhabitants of which are allies of the emperor.

GHENT, or **GAUNT**, a city of France, capital of the department of the Scheldt, and late capital of the province of Austrian Flanders. It is seated on four navigable rivers, the Scheldt, the Lys, the Lieve, and the Moeze. It is 26 miles N. W. of Brussels. Lon. 3. 49. E. Lat. 51. 3. N.

GHERIAH, or **GHERLAH**, a town of Hindostan, in Concan, on the W. or pirate coast, 80 miles N. N. W. of Goa. Lon. 73. 8. E. Lat. 16. 45. N.

GHEYSSIQUAS, a nation of Hottentots, who inhabit a district of South Africa, near Caffraria, from which, as well as from

the country of the Bremas and Briquas, it is separated by a chain of mountains.

GHINIA, in botany, a genus of the diandria monogynia class and order. Natural order, Personatæ. Calyx five-toothed, teeth acuminate; corolla two-lipped; drupe containing a nut, four or five-celled. It has two species.

GHIRGONG, or **GHERGONG**, a city of Hindostan, the capital of Assam, seated on the Burrampooter, 448 miles E. of Patna.

GHISLAIN, **St.** or **St. GHILAN**, a town of France, in the department of the North, and late province of French Hainault, five miles W. of Mons.

GHIZNI, or **GAZNA**. See **GAZNA**.

GHOUMEL, a town of Africa, in the kingdom of Pholey, on the Joto. Lon. 11. 15. W. Lat. 16. 12. N.

GHOWRI, a town of Asia, in the kingdom of Balk. Lon. 66. 56. E. Lat. 35. 40. N.

GIAGH, in chronology, a cycle of 12 years, in use among the Turks and Cathayans. Each year of the giagh bears a name of some animal; the first that of a mouse; the second that of a bullock; the third a lynx or leopard; the fourth a hare; the fifth a crocodile; the sixth a serpent; the seventh a horse; the eighth a sheep; the ninth a monkey; the tenth a hen; the eleventh a dog; and the twelfth a hog. They also divide the day into twelve parts, called giaghs, and distinguish them by the names of animals. Each giagh contains two of our hours, and is divided into eight kehs; so that a keh is a quarter of our hour.

GIANT, [*geant*, French; *gigas*, Latin,] a man of size above the ordinary rate of men; a man unnaturally large. It is observable, that the idea of a giant is always associated with pride, brutality, and wickedness. The tradition of all ages have furnished us with so many extravagant accounts of giants of incredible bulk and strength, that the existence of such people is now generally disbelieved. It is commonly thought, that the stature of man has been the same in all ages; and some have even pretended to demonstrate the impossibility of the existence of giants mathematically. Of these our countryman M'Laurin has been the most explicit. But his arguments and comparisons, drawn from the disproportion between the cohesion of parts in small models and large works, of human workmanship, are by no means conclusive; because, along with an increase of stature in any animal, we must always suppose a proportional increase in the cohesion of the parts of its body. Large works sometimes fail when constructed on the plan of models, because the cohesion of the materials whereof the model is made, and of the large work, are the same; but a difference in this respect will produce a very remarkable difference in the ultimate result. Thus, suppose a model is made of fir-wood, the model may be firm and strong enough; but a large work made also of fir, when executed according to the plan of the model, may be so weak that it will fall to pieces from its own weight. If, however, we make use of iron for the large work instead of fir, the whole will be sufficiently strong, even though made exactly according to the plan of the model. The like may be said with regard to large and small animals. If we could find an animal whose bones exceeded in hardness and strength the bones of other animals as much as iron exceeds fir, such an animal might be of a monstrous size, and yet be exceedingly strong. In like manner, if we suppose the flesh and bones of a giant to be greatly superior in hardness and strength to those of other men, the great size of his body will be no objection at all to his strength. The whole controversy, therefore, concerning the existence of giants, must rest on the credibility of the accounts given by those who profess to have seen them, and not on any arguments drawn *a priori*. In the scripture we are told of giants, who were produced from the marriages of the sons of God with the daughters of men. This passage indeed has been differently interpreted, so as to render it doubtful whether the word translated giants does there imply any extraordinary stature. In other parts of scripture, however, giants, with their dimensions, are mentioned in such a manner that we cannot possibly doubt; as in the case of Og king of Bashan, Goliath, and his brethren. 1 Chron. xx. 4—8. The Rev. Mr. Gun minister of Latheron, in Caithness, mentions William Sutherland the last proprietor of Berrydale castle, who lived in the end of the 15th century, and measured nine feet five inches high.

GIANT'S CAUSEWAY, in geography and natural history, a vast collection

collection of Basaltic pillars in the county of Antrim in Ireland. See BASALTES. The principal or grand causeway (for there are several less considerable and scattered fragments of them,) consists of a most irregular arrangement of many hundred thousands of columns of a black kind of rock, hard as marble: almost all of them are of a pentagonal figure, but so closely and compactly situated on their sides, though perfectly distinct from top to bottom, that scarce any thing can be introduced between them. The columns are of an unequal height and breadth; some of the highest, visible above the surface of the strand, and at the foot of the impending angular precipice, may be about 20 feet; they do not exceed this height, at least none of the principal arrangement. How deep they are fixed in the strand, was never yet discovered. This grand arrangement extends nearly 200 yards, visible at low water; how far beyond is uncertain: from its declining appearance, however, at low water, it is probable it does not extend under water to a distance any thing equal to what is seen above. The breadth of the principal causeway, which runs out in one continued range of columns, is, in general, from 20 to 30 feet; at one place or two it may be nearly 40 for a few yards. In this account are excluded the broken and scattered pieces of the same kind of construction, that are detached from the sides of the grand causeway, as they do not appear to have ever been contiguous to the principal arrangement, though they have frequently been taken into the width: which has been the cause why many very dissimilar representations of this causeway have been given. The highest part is the narrowest, at the very foot of the impending cliff from whence the whole projects, where, for four or five yards, it is not above 12 or 15 feet wide. The columns of this narrow-part incline from a perpendicular a little to the westward, and form a slope on their tops, by the very unequal height of the columns on the two sides, by which an ascent is made at the foot of the cliff, from the head of one column to the next above, gradually, to the top of the great causeway, which, at the distance of six yards from the cliff, obtains a perpendicular position; and lowering in its general height, widens to about 20 or between 20 and 30 feet, and for 100 yards nearly is always above water. The tops of the columns for this length being nearly of an equal height, they form a grand and singular parade, that may be easily walked on, rather inclining to the water's edge. But from high-water-mark, as it is perpetually washed by the beating surges on every return of the tide, the platform lowers considerably, and becomes more and more uneven, so as not to be walked on but with the greatest care. At the distance of 150 yards from the cliff, it turns a little to the east for 20 or 30 yards, and then sinks into the sea. The figure of these columns is almost unexceptionally pentagonal, or composed of five sides; there are very few of any other figure: some few are of three, four, and six sides, but the generality of them are five-sided, and the spectator must look very nicely to find any of a different construction: yet what is very extraordinary, there are not two columns in ten thousand to be found, that either have their sides equal among themselves, or whose figures are exactly alike. Nor is the composition of these columns less deserving attention. They are not of one solid stone in an upright position; but composed of several short lengths, curiously joined, not with flat surfaces, but articulated into each other like ball and socket, or like the joints in the vertebrae of some of the larger kinds of fish, the one end at the joint having a cavity, into which the convex end of the opposite one is exactly fitted. This is not observable but by disjoining the two stones. The depth of the concavity or convexity is generally about three or four inches. And the convexity, and the correspondent concavity, are not conformed to the external angular figure of the column, but exactly round, and as large as the size or diameter of the column will admit. Consequently, as the angles of these columns are in general extremely unequal, the circular edges of the joint are seldom coincident with more than two or three sides of the pentagonal, and from the edge of the circular part of the joint to the exterior sides and angles they are quite plain. It is still farther very remarkable, that the articulations of these joints are frequently inverted; in some the concavity is upwards, in others the reverse. This occasions that variety and mixture of concavities and convexities on the tops of the columns, which is observable throughout the platform of this causeway, yet without any discoverable regularity with respect to the number of either. The length of these particular stones, from joint to joint, is various:

in general, from 18 to 24 inches, and, for the most part, longer toward the bottom of the columns than nearer the top, and the articulation of the joints something deeper. The size or diameter of the columns is as different as their length and figure; in general, they are from 15 to 20 inches. There are no traces of uniformity discovered throughout the whole combination, except in the form of the joint, which is invariably by an articulation of the convex into the concave of the piece next above or below it; nor are there any traces of a finishing in any part, either in height, length, or breadth, of this curious causeway. If there is here and there a smooth top to any of the columns above water, there are others just by, of equal height, that are more or less convex or concave, which shew them to have been joined to pieces that have been washed or by other means taken off. And undoubtedly those parts that are always above water have, from time to time, been made even; and the remaining surfaces of the joints must naturally have been worn smoother, by the constant friction of the weather and walking, than where the sea, at every tide, is beating upon it, and continually removing some of the upper stones, and exposing fresh joints. As these columns preserve their diameters from top to bottom, in all the exterior ones, which have two or three sides exposed to view, the same may be with reason inferred of the interior columns whose tops only are visible. Yet what is very extraordinary, and equally curious, is, that notwithstanding the universal dissimilitude of the columns, both as to their figure and diameter, and though perfectly distinct from top to bottom, yet is the whole arrangement so closely combined at all points, that hardly a knife can be introduced between them either on the sides or angles. It is really a most curious piece of entertainment, to examine the close texture and nice insertion of such an infinite variety of angular figures, as are exhibited on the surface of this grand parade. From the infinite dissimilarity of the figures of these columns, this will appear a most surprising circumstance to the curious spectator, and would incline him to believe it a work of human art, were it not inconceivable, that the invention of man should construct and combine such an infinite number of columns, which should have a general apparent likeness, and yet be so universally dissimilar in their figure, as that, from the minutest examination, not two in ten or twenty thousand should be found, whose angles and sides are equal among themselves, or of the one column to those of the other. That this is the production of nature, the attentive spectator cannot doubt, who carefully surveys the general form and situation, with the infinitely various figuration of the several parts of this causeway. There are no traces of regularity or design in the outlines of this curious phenomenon; which, including the broken and detached pieces of the same kind, are extremely scattered and confused, and, whatever they might originally, do not at present appear to have any connection with the principal causeway, as to any supposable design or use in its first construction; and as little design can be inferred from the figure or situation of the several constituent parts. The whole is, indeed, extremely confused, disuniform, and destitute of every appearance of use or design in its original construction. But what, beyond dispute, determines its original to be natural, is, that the very cliffs, at a great distance from the causeway, especially in the bay to the eastward, exhibit at many places the same kind of columns, figured and jointed in all respects like those of the grand causeway. Some of them are seen near to the top of the cliff, which in general, in these bays to the E. and W. of the causeway, is near 300 feet in height; others again are seen about midway, and at different elevations from the strand. A very considerable exposure of them is seen in the very bottom of the bay to the eastward, near 100 rods from the causeway, where the earth has evidently fallen away from them upon the strand; and exhibits a most curious arrangement of many of these pentagonal columns, in a perpendicular position, supporting, in appearance, a cliff of different strata of earth, clay, rock, &c. to the height of 150 feet or more, above. Some of these columns are between 30 and 40 feet high, from the top of the sloping bank below them; and, being longest in the middle of the arrangement, shortening on either hand in view, they have obtained the appellation of organs, from a rude likeness in this particular to the frontal tubes of that instrument; and as there are few broken pieces on the strand near it, probably the outside range of columns that now appear is really the original exterior line, toward the sea, of this collection. But

how far they extend internally into the bowels of the incumbent cliff, is unknown. The very substance, indeed, of that part of the cliff which projects to a point, between the two bays on the E. and W. of the causeway, seems composed of this kind of materials; for besides the many pieces that are seen on the sides of the cliff that circulate to the bottom of the bays, particularly the E. side, there is, at the very point of the cliff, and just above the narrow and highest part of the causeway, a long collection of them seen, whose heads or tops just appearing without the sloping bank, plainly shew them to be in an oblique position, and about half-way between the perpendicular and horizontal. The heads of these, likewise, are of mixed surfaces, convex and concave; and the columns evidently appear to have been removed from their original upright, to their present inclining or oblique position, by the sinking of the cliff.

GIANT'S GRAVE, a village of Ireland, near Sligo, where there are some massive ancient monuments of stone resembling those of Stonehenge.

GIBBET, or **GIBET**. See **GALLOWES**. The Fr. *gibet*, a gallows, is supposed to be derived from the Arabic *gibel*, "mount or elevation of ground;" as gibbets are usually placed on hills or eminences.

GIBBIO, **CASTELLO DI MONTE**, a town of the late Cisalpine republic, in the department of Crostolo, and late duchy of Modena.

GIBBON, **EDWARD**, Esq. a late celebrated English historian, born at Putney, in Surrey, April 27, 1737. He was the eldest son of Edward Gibbon, Esq. In 1745 he was sent to the grammar-school at Kingston; in January 1749, to that of Westminster, and in April 1752, to that of Oxford, where he matriculated in Magdalen college; the professors of which he blames greatly for their remissness and inattention to his moral conduct and religious principles. In consequence of this he became a convert to the Roman Catholic faith in his 16th year. To cure the young catholic of his errors, and bring him back to the Protestant faith, his father, within three weeks after his conversion, (June 30, 1753,) sent him to Switzerland, and entrusted him to the tutorage of Mr. Pavilliard, a Calvinist minister at Lausanne, whom Mr. Gibbon mentions with gratitude, as a most excellent preceptor. Under his tuition, he made rapid progress in the Latin, Greek, and French classics; in history, geography, logic, and metaphysics; and was also soon reclaimed from the errors of Popery: so that on Christmas 1754, he received the sacrament in the church of Lausanne. Thus had he communication with three different churches before he was 18 years old. These jarring opinions, however, successively adopted and rejected, and the repeated changes so rapidly made from the one to the other, perhaps contributed to weaken our author's faith in revelation, and to lead to his final change to Deism, as much as his perusal of M. Voltaire's writings, or his conversation with that author, to whom he introduced himself in 1757. In spring 1758, he was recalled to England, and was agreeably received by his father; at whose house at Beriton in Hampshire, he finished a work he had begun at Lausanne, entitled "Essai sur l'Etude de la Littérature," which he published in 1761, 12mo. with a dedication to his father. Previously to this period, he had been appointed a captain in the South Hampshire Militia, in which he served two years, and which was of use to him, by making him better acquainted with English manners, principles, and parties, than perhaps he might otherwise have been. After the peace in 1763, he went abroad; and after visiting Paris, where he was introduced to Messrs. D'Alembert and Diderot, returned to his favourite residence at Lausanne. Having spent some time there, he made the tour of Italy; and at Rome, on the 15th October 1764, while musing amidst the ruins of the capitol, the idea of his great work first started into his mind. Upon his return to Hampshire in June 1765, he found his father involved in pecuniary difficulties, and to relieve him, consented to the sale of part of the estate. After commencing a history of the revolutions of Switzerland, which he suppressed, he engaged in a Journal entitled, "Memoires Littéraires de la Grande Bretagne," and published 2 vols. for 1767 and 1768; but his partner in this undertaking, a native of Switzerland, going abroad, when the third volume was nearly finished, the work was discontinued. Bishop Warburton having about this time published an interpretation of the 6th book of Virgil's *Æneid*, he criticised it with equal asperity

and success. But it is thought, that if the bishop had then possessed his former mental vigour, he would have chastised Mr. Gibbon in such a manner, as to have made him afterwards somewhat more modest in his great work; in which, with all his petulant confidence, he often shews great inaccuracy in his quotations. Nor could it well be otherwise, as he himself acknowledges, that he often contented himself with borrowing his quotations, not from the original authors, but at second hand. But the taste of the times favouring the spirit of scepticism that appeared in his work, errors of this kind, which in a defender of Christianity would have been reckoned unpardonable, as so many pious frauds intended to deceive the reader, were either entirely overlooked, or considered as very venial faults, in his "History of the Decline and Fall of the Roman Empire." Of this work the first volume was published in 1776, and met with extraordinary success; the second and third volumes appeared in 1781; and the fourth, fifth, and sixth, in 1787, established Mr. Gibbon's fame as a historian. Encomiums were lavished on him from all quarters, to such a pitch indeed, that some of them, particularly those of Mr. Hume and Dr. Robertson, have even been reckoned false. That Mr. Hume should have been highly delighted with a work tending strongly to enforce his own principles, is not surprising; but the high panegyric bestowed by a Minister of the Gospel, upon a work, one main object of which is to prove that Christianity is not of divine original, is certainly quite out of character. But others, while they give our author full credit for acuteness of penetration, fertility of genius, luxuriance of fancy, elegance of style, harmony of language, and beauty of epithets, &c. object, that, "the uniform stateliness of his diction sometimes imparts to his narrative a degree of obscurity, unless he descends to the miserable expedient of a note to explain the minuter circumstances;" and that, "his style on the whole is much too artificial; and this gives a degree of monotony to his periods, which extends almost to the turn of his thoughts." "But a more serious objection (they justly add,) is his attack upon Christianity; the loose and disrespectful manner in which he mentions many points of morality, regarded as important on the principles of natural religion; and the indecent allusions and expressions, which too often occur in the work. An attack upon Christianity is not censurable merely as such; but in that case, the attack will never be carried on in an insidious manner, and with improper weapons; and Christianity itself, so far from dreading, will invite every mode of fair and candid discussion. Our historian often makes, when he cannot readily find, an opportunity to insult the Christian religion. Such indeed is his eagerness in the cause, that he stoops to the most despicable pun, or to the most awkward perversion of language, for the pleasure of turning the scripture into ribaldry, or calling Jesus an impostor. Yet of the Christian religion has Mr. Gibbon himself observed, that 'it contains a pure, benevolent, and universal system of ethics, adapted to every duty and every condition of life.' Such an acknowledgement, and from such a writer, too, ought to have due weight with a certain class of readers, and of authors likewise; and lead them seriously to consider, how far it is consistent with the character of good citizens, to endeavour by sly insinuations, oblique hints, indecent sneers, and profane ridicule, to weaken the influence of so pure and benevolent a system as that of Christianity, acknowledged to be admirably calculated for promoting the happiness of individuals and the welfare of society." (Supplement to the Encyc. Brit. Vol. I. p. 707.) Various answers to Mr. Gibbon's attack on Christianity, were published by Dr. Chelsum, Dr. Randolph, Lord Hailes, Dr. Watson bishop of Llandaff, Dr. White, Mr. Aphorpe, Mr. Davis, Mr. Taylor, Dr. Priestley, and others. To most of these our author made no reply, though his posthumous memoirs shew he felt the weight of these answers, particularly those of Lord Hailes, Dr. White, and Mr. Taylor. His constitution had suffered much from repeated attacks of the gout, and a swelling of his ancles; and after having been often tapped for a hydrocele, he died at London, of the gout in his stomach, on the 16th Jan. 1794, in the 57th year of his age.

GIBBOSITY, in surgery, denotes any protuberance or convexity of the body, as a person hump-backed. Infants are much more subject to gibbosity than adults, and it oftener proceeds from external than internal causes. A fall, blow, or the like, frequently thus distorts the tender bones of infants. When it pro-

ceeds from an internal cause, it is generally from a relaxation of the ligaments that sustain the spine, or a caries of its vertebrae; though the spine may be inflected forward, and the vertebrae thrown out by a too strong and repeated action of the abdominal muscles. This, if not timely redressed, grows up and fixes as the bones harden, till in adults it is totally irremediable: but when the disorder is recent, and the person young, there are hopes of a cure. The common method is by a machine of pasteboard, wood, or steel, which is made to press principally on the gibbous part; and this by long wearing may set all right.

GIBBOUS, in astronomy, is used in respect to the enlightened parts of the moon, whilst she is moving from the first quarter to the full, and from the full to the last quarter: for all that time the dark part appears horned or falcated; and the light one hunched out, convex, or gibbous.

GIBEON, a city seated on an eminence about 40 furlongs N. of Jerusalem, and not far from Gibeah.

GIBEONITES, an ancient nation of Canaan, who, hearing of Joshua's great conquests, saved their lives at the expence of their liberty by a representation of their belonging to a very remote country, and their desire of making an alliance with the Hebrews. See Joshua, ix. 3—27. The Gibeonites were descended from the Hivites, and possessed four cities; viz. Chephirah, Beeroth, Kirjathjearim, and Gibeon; which were afterwards given to the Benjaminites, except the last, which fell to the tribe of Judah. The Gibeonites continued subject to those burdens which Joshua had imposed on them, and were very faithful to the Israelites, till the dispersion of that nation.

GIBRALEON, a town of Spain, 44 miles W. of Seville.

GIBRALTAR, a famous promontory, or rather peninsula, of Spain, in Andalusia, but belonging to Great Britain. By the ancients it was named Calpe, and was also called one of the Pillars of Hercules; by the Arabians it is called Gebel Tarek, that is, "the mount of Tarek," from Tarek, the name of the Saracen general who conquered Spain in the beginning of the 8th century. The whole is an immense rock, rising perpendicularly about 440 yards, measuring from N. to S. about two English miles, but not above one in breadth, from E. to W. The longitude of this promontory is 5° 4' 0" W. of Greenwich, and its latitude 36° 4' 44" N. The time of high water at the time of the full and change of the moon, happens here precisely at noonday.

GIBRALTAR, a town on the above promontory, which lies along the bay on the W. side of the mountain on a decline; by which the rains pass through it, and keep it clean. The old town was considerably larger than the new, which at present consists of between 400 and 500 houses. It lies 16 miles N. of Ceuta, 45 S. E. of Cadiz. Lon. 5. 17. W. Lat. 36. 8. N. The bay is very beautiful and capacious, being in breadth about five miles, and in length eight or nine, with several small rivers running into it. It is very advantageous to the place. There is no ground to be found in the middle of it at 100 fathoms depth, so that a squadron may lie there in great safety; the breezes from it are very refreshing; and it contributes likewise to the subsistence of the inhabitants, by supplying them with plenty of fish. Gibraltar is esteemed of very great consequence to Britain. It not only gives the command of the Straits, and their navigation, but affords refreshment and accommodation to our fleets in time of war, and to our merchantmen at all times. It hinders a ready communication by sea between the different ports of France and Spain, and of course, hinders the junction of their fleets and squadrons, or at least renders it so difficult as to be a perpetual check upon the ambition of these powers. It awes also the piratical states of Barbary, and the emperor of Morocco; inasmuch, that our commerce is more safe than that of any other European power, which gives us great advantages in point of freight. It is otherwise highly favourable to our trade in the Mediterranean and Levant. It procures us the respect of the Italian and other powers; who, though far distant from Britain, consider this as an instance of her power to hurt or assist them. It also saves us the expence of squadrons and convoys, upon any disputes or disturbances that may happen among those powers, and which would otherwise be necessary for the protection of our navigation. The inhabitants, exclusive of the British subjects dependent on the garrison, or who reside there from other motives, consist of some Spaniards, a few Portuguese, a considerable number of Genoese, and about as many Jews; making in the whole, according to Dr. Campbell, between 2 and

3,000, without reckoning the garrison, which usually consists of between 3 and 4,000 men; but during the last siege was double that number.

GIBRALTAR, STRAITS OF, a narrow sea, which forms the communication between the Atlantic Ocean and the Mediterranean, thereby dividing Europe from Africa; and runs from W. to E. about 13 leagues. In this strait there are three remarkable promontories or capes on the Spanish side, and as many opposite to them on the Barbary side. The first of these, on the side of Spain, is Cape Trafalgar, opposite to which is Cape Spartel; and in the neighbourhood of this stood the fortress of Tangier, once in the possession of the British. The next on the Spanish side is Tarisa; and over against it lies Malabata, near the town of Alcazar, where the straits are about five leagues broad. Lastly, Gibraltar, facing the mountain of Abyla, near the fortress and town of Ceuta, now in our possession, which, make the eastern entry of the straits.

GIBSON, Dr. EDMUND, bishop of London, was born at Knipe in Westmoreland, in 1669. He early displayed his knowledge in several writings and translations, which recommended him to the patronage of Archbishop Tension, who appointed him his domestic chaplain; and soon after rector of Lambeth, and archdeacon of Surrey. Becoming thus a member of the convocation, he defended his patron's rights, as president, in eleven pamphlets; he then completed his scheme of the legal duties and rights of the English clergy, under the title of "Codex Juris Ecclesiastici Anglicani," in folio. In 1720 he was promoted to the bishopric of London, and spent the latter part of his life in publishing letters, charges, occasional sermons, and tracts against the prevailing immoralities of the age. His pastoral letters are justly esteemed masterly productions against infidelity and enthusiasm. His other publications are, 1. An edition of Drummond's Polemo-Middinia, and James V.'s Cantilena Rustica, with notes. 2. The Chronicon Saxonum, with a Latin translation, and notes. 3. Reliquiae Spelmanianae, the posthumous works of Sir Henry Spelman, relating to the laws and antiquities of England. 4. An edition of Quintilian de Arte Oratoria, with notes. 5. An English translation of Camden's Britannia, with additions, 2 vols. folio: and, 6. A number of small pieces, that have been collected and printed in three volumes folio. He died, aged 79, in September 1748. With regard to his character, he was a true friend to the established church and government, and as great an enemy to persecution. He was usually consulted by the most learned and exalted personages in church and state, and the greatest deference was paid to his judgement. He possessed the social virtues in an eminent degree; his beneficence was very extensive; and he had so much justice as well as generosity, that he freely gave 2,500l. left him by Dr. Crow, who was once his chaplain, to Crow's own relations, who were very poor.

GIDEON, [גִּדְּוֹן, Heb. i. e. a destroyer,] the son of Joash, a Manassite, who had a very extraordinary call to deliver the Israelites from the oppression of the Midianites. Having effected their deliverance by supernatural aid, he was chosen judge of Israel, A. M. 2759, and died in 2798.

GIEN, a town of France, in the department of Loiret, and late province of Orleans, 33 miles S. E. of Orleans.

GIENGEN, an imperial town of Suabia, on the Brentz, 20 miles W. of Donauwert.

GIERACE, an episcopal town of Naples, in Calabria Ultra, 34 miles N. of Reggio.

GIessen, a strong town of Hesse Cassel, on the Lahn, 36 miles N. E. of Mentz.

GIFT, [*donum*, Lat.] in law, a conveyance which passeth either in lands or goods; and is of a larger extent than a grant, being applied to things moveable and immoveable; yet as to things immoveable, it is properly applicable only to lands and tenements given in tail; but gift and grant are too often confounded.

GIGG, or **JIG**, in music or dancing, a gay, brisk, sprightly composition, and yet in full measure, as well as the allemande, which is more serious. Menage takes the word to arise from the Italian *giga*, a musical instrument mentioned by Dante.

GIGGLEWICK, a town in the West Riding of Yorkshire, half a mile from Settle, on the Ribble; where, at the foot of a mountain, is a spring, the most noted in England for ebbing and flowing sometimes thrice in an hour, and the water subsides three quarters of a yard at the reflux, though the sea is thirty miles off. At this town is an eminent free grammar-school;

and near it is a quarry of flags, slate, and stone, with a good lime-kiln.

GIGHA, GIGA, or GIGO, an island of Scotland, on the W. coast of Kintyre, in Argyleshire, 11 miles E. S. E. of Ilay; 7 miles long, from N. E. to S. W. and $2\frac{1}{2}$ broad. The greater part of it is arable.

GIGLIO, an island on the coast of Sienna in Tuscany, 33 miles S. S. E. of Elva. Lon. 11. 16. E. Lat. 42. 23. N.

GIGNAC, a town of France, in the department of Herault, seated on the Herault, $13\frac{1}{2}$ miles W. of Montpellier.

GIHON, in ancient geography, one of the rivers of Paradise; according to Wells, the eastern branch of the Euphrates, into which it divides after its junction with the Tigris.

GIJON, a sea-port of Spain, in Asturia, with an ancient castle; formerly the residence of K. Pelagius and his successors. It is 18 miles N. of Oviedo.

GILAN, or GHILAN, a considerable province of Persia, lying on the S. W. side of the Caspian sea. It is supposed to be the Hyrcania of the ancients. Resht is the capital.

GILBERD, or GILBERT, WILLIAM, a physician, born at Colchester, in 1540, the eldest son of the recorder of that borough. Having spent some time in both universities, he went abroad; and at his return settled in London, where he practised with considerable reputation. He became a member of the college of physicians, and physician in ordinary to Q. Elizabeth, who gave him a pension. He was also physician to K. James I. He died in 1603, aged 63; in Colchester, where a handsome monument was erected to his memory. His books, globes, instruments, and fossils, he bequeathed to the college of physicians, and his picture to the school-gallery at Oxford. He wrote, 1. *De Magnete, mag-*

neticisque Corporibus, et de magno Magnete Tellure, Physiologia nova; Lond. 1600, fol. 2. *De Mundo nostro sublunari, Philosophia nova*; Amsterdam, 1651, 4to. He also invented two mathematical instruments for finding the latitude at sea without the help of sun, moon, or stars. A description of these instruments was afterwards published by Thomas Blondville in his *Theoriques of the planets*.

GILBERTIA, in botany, a genus of the monogynia order, and decandria class. Calyx five-toothed; corolla deeply five-parted; nectary ten-parted, with lanceolate segments; fruit six-celled. It has but one species.

GILBERTINES, an order of religious, thus called from St. Gilbert of Sempringham, in Lincolnshire who founded it about 1148. The monks observed the rule of St. Augustine; and were accounted canons; and the nuns that of St. Benedict.

GILBERT'S ISLAND, an island near the S. W. coast of Terra del Fuego. Lon. 71. 7. W. Lat. 55. 13. S.

GILBOA, in ancient geography, mountains of Samaria, stretching from W. to E. on the confines of the half-tribe of Manasseh, and of the tribe of Issachar.

GILDAS, surnamed **THE WISE**, a celebrated British monk born in Wales in 511. Where he was educated is uncertain. Some say he went over to Ireland; others, that he visited France and Italy. All agree, that after his return to England he became a most assiduous preacher of the gospel. Du Pin says he founded a monastery at Venetia in Britain. Gildas is the only British author of the sixth century whose works are printed. His history of Britain is valuable on account of its antiquity, and as containing the only information we have concerning the times of which he wrote; though his style is inelegant.

GILDING.

GILDING, the art of spreading or covering a thing over with gold, either in leaf or liquid. This art was known among the ancients, though it never arrived among them at the perfection to which the moderns have carried it. Pliny assures us, that the first gilding seen at Rome was after the destruction of Carthage, under the censorship of Lucius Mummius, when they began to gild the ceilings of their temples and palaces; the Capitol being the first place on which this enrichment was bestowed. The lustre and beauty of gold have occasioned several inquiries, and discoveries concerning the different methods of applying it to different substances. Hence the art of gilding is very extensive, and contains many particular operations and various management.

OF GOLD-LEAF. There are three kinds of gold-leaf in common use. Pure gold-leaf, which is made by hammering gold till it is sufficiently thin (see **GOLD-BEATING**). Pale leaf-gold, which has a greenish colour, and is made in the same way of gold alloyed with silver. Dutch gold, which is brought from Holland, and is in fact only copper-leaf coloured by the fumes of zinc. It is much cheaper than true leaf-gold, and is very useful where large quantities of gilding are wanted, which can be defended from the weather, and where great nicety is not required; but it changes its colour entirely when exposed to moisture; and indeed, in all cases, its beauty is soon impaired, unless well secured by varnish. It is therefore only a cheap substitute for true gold-leaf, which may be useful where durability is not an object.

OF THE INSTRUMENTS NECESSARY FOR GILDING.

The first instrument is the **CUSHION**, for receiving the leaves of gold from the books in which they are bought. It is made by covering a board of about eight inches square, with a double thickness of flannel: and over that a piece of buff-leather, and fastening it tight round the edges.

The **KNIFE** for cutting the leaves into the requisite sizes should be made like a pallet-knife, and should not have its edge too sharp.

The **TIP** is a tool made by fastening the long hairs of a squirrel's tail between two cards; and is used for taking up the gold-leaf after it is cut, and applying it to the article to be gilded.

A **FITCH-PENCIL** is used for the same purpose as the last, in

taking up very small bits of gold-leaf. A ball of cotton is necessary for pressing down the leaf, after it is laid on. A large camel's-hair-brush is used for dusting the work, and clearing away the superfluous gold.

OF THE DIFFERENT KINDS AND METHODS OF GILDING.

OIL-GILDING. First prime your work with boiled linseed-oil and white-lead; and when that is dry, cover it over with a thin coat of gold-size, made of stone-ochre ground in fat oil. When that is so dry as to feel clammy to the fingers, or to be what the gilders call tacky, it is fit for gilding. Having spread your leaves upon the cushion, cut them into slips of the proper width for covering your work. Then breathe upon your tip, which, by moistening it, will cause it to take up the leaves from the cushion. Having applied them by the tip on the proper parts of your work, press them down by the ball of cotton. Observe to repair, by putting small pieces of gold on any parts which you have omitted to cover. When all your work is sufficiently covered, let it dry, and clean it off with the brush. This sort of gilding is the easiest, least expensive, and stands the weather best, and may be cleaned with a little water at any time; but wants the lustre of burnished gilding.

BURNISHED GILDING. This is the sort of gilding generally used for picture-frames, looking-glasses, &c. The wood intended to be gilt in this manner, should first be well sized, and then covered with seven or eight coats of size and whiting, so as to form a body of considerable thickness. Having got a sufficient quantity of whiting upon the work, it must be carefully cleaned, taking care to free all the cavities and hollows from the whiting that may have choked them up, and by proper moulds and tools restoring the sharpness of the mouldings intended to be shewn. It is then to receive a coat of size, which is made by boiling Armenian bole with parchment-size. This must also remain till it is sufficiently dry for gold. It must not be quite dry, therefore it would not be prudent to lay on more at a time than can be gilt before it becomes too dry. The work being thus prepared, place it a little declining from you; and having ready a cup of clean water, and some hair-pencils, moisten a part of the work, and then apply the gold by the tip to the moistened part. The gold will immediately,

diately adhere close to the work: proceed to wet the next part, and apply the gold as before, repeating this operation till the whole is completed; taking care not to let any drops of water come upon any part of the gold already laid on. Care should therefore be taken that no part be missed in going over it at first as it is not so easily mended as the oil-gilding. The work being thus gilt, it is suffered to remain about 24 hours; when the parts that are designed to be burnished, are polished with a dog's tooth, or, what is better, with an agate burnisher. The gilding must not be quite dry when burnished; there is a state proper for the purpose, which is only to be known by experience.

JAPANNER'S GILDING. The gilding of japanned work consists in drawing with a hair-pencil, in gold size, the intended ornaments, and afterwards applying gold-leaf, or gold-powder. The gold-size may be prepared in the following manner: Take of linseed-oil, and of gum animi, four ounces. Set the oil to boil in a proper vessel, and then add the gum animi gradually in powder, stirring each quantity about in the oil till it appears to be dissolved, and then putting in another, till the whole is mixed with the oil. Let the mixture continue to boil, till, on taking a small quantity out, it appears of a thicker consistence than tar, and then strain the whole through a coarse cloth, and keep it for use; but it must, when applied, be mixed with vermilion and oil of turpentine. Having laid on the gold-size, and suffered it to dry, the gold-leaf is applied in the usual way; or if it be not wanted to shine so much, gold-powder is applied, which is made by grinding gold-leaf upon a stone with honey, and afterwards washing the honey away with water. If the gilding is, to be varnished over, Dutch gold may be used, or *aureum musivum* may be used instead of real gold-powder.

TO WRITE ON PAPER WITH LETTERS OF GOLD. Put some gum-arabic into common writing-ink, and write with it in the usual way. When the writing is dry, breathe on it; the warmth and moisture soften the gum, and will cause it to fasten on the gold-leaf; which may be laid on in the usual way, and the superfluous part brushed off. Or instead of this, any japanners' size may be used.

TO LAY GOLD UPON WHITE EARTHENWARE, OR GLASS. Procure some japanners' gold-size, and with it draw your design upon the vessel to be gilt, moistening the gold-size, as you find necessary, with oil of turpentine. Set your work in a clean place to dry, for about an hour, and then place it so near the fire, that you could but just bear the heat of it with your hand for a few seconds. Let it remain there till it feels quite tacky or clammy; then, having procured a cushion, and some leaf-gold, cut it into slips of the proper size, and lay it on with the little cotton ball. When the gold is all on, put the ware into an oven to be baked for two or three hours. Glasses, &c. may also be gilt, by drawing the figures with shell-gold mixed with gum-arabic, and a little borax. Then apply sufficient heat to it; and, lastly, burnish it.

GILDING ON GLASS OR PORCELAIN, BY BURNING IN. Dissolve gold in aqua regia, and evaporate the acid by heat, you will obtain a gold powder: or precipitate the gold from the solution by pieces of copper. Lay this gold on with a strong solution of borax and gum-water, and it will be ready for burning in.

GILDING METALS. One method of applying gold upon metals is by first cleaning the metal to be gilt; then gold-leaf is laid on it, which, by means of rubbing with a polished blood-stone, and a certain degree of heat, are made to adhere perfectly well. In this manner silver-leaf is fixed and burnished upon brass, in the making of what is called French plate; and sometimes also gold-leaf is burnished upon copper and iron.

GILDING BY AMALGAMATION. A better method is, by previously forming the gold into paste, or amalgam, with mercury. In order to obtain an amalgam of gold and mercury, the gold is first to be reduced into thin plates or grains, which are heated red-hot, and thrown into mercury previously heated, till it begins to smoke. Upon stirring the mercury with an iron rod, the gold totally disappears. The proportion of mercury to gold is generally as six or eight to one. The method of gilding by amalgamation is chiefly used for gilding copper, or an alloy of copper, with a small portion of zinc, which more readily receives the amalgam, and is also preferable on account of its colour, which more resembles that of gold than the colour of copper. When the metal to be gilt is

wrought or chased, it ought to be previously covered with quicksilver before the amalgam is applied, that this may be easier spread; but when the surface of the metal is plane, the amalgam may be directly applied to it. The metal required to be gilt is first rubbed over with a little aquafortis, by which the surfaces cleaned from any rust or tarnish that might prevent the union of the two metals. The amalgam being then equally spread over the surface by means of a brush, the mercury is evaporated by a heat just sufficient for that purpose: for if it be too great, part of the gold may also be expelled, and part of it will run together, and leave some of the surface of the metal bare. While the mercury is evaporating the piece is to be, from time to time, taken from the fire, that it may be examined; that the amalgam may be spread more equally by means of a brush; that any defective parts of it may be again covered, and that the heat may not be too suddenly applied to it. When the mercury is evaporated, which is known by the surface becoming entirely of a dull-yellow colour, the metal must then undergo other operations, by which the fine gold-colour is given to it. First, the gilded piece of metal is rubbed with a scratch-brush (which is a brush composed of brass wire) till its surface is made smooth; then it is covered over with a composition called gilding-wax, and is again exposed to the fire till the wax is burnt off. This wax is composed of bee's-wax, frequently mixed with some of the following substances: red ochre, verdigris, copper scales, alum, vitriol, borax; but, according to Dr. Lewis, the saline substances are sufficient, without any wax. By this operation the colour of the gilding is heightened; and the effect seems to be produced by a perfect dissipation of some mercury remaining after the former operation. The gilt surface is then covered over with a saline composition, consisting of nitre, alum, and vitriolic salt, ground together, and mixed up into a paste with water or urine. The piece of metal thus covered is exposed to a certain degree of heat, and then quenched in water. By this method its colour is further improved, and brought nearer to that of gold. This effect seems to be produced by the acid of the nitre (which is disengaged by the sulphuric acid of the alum, during the exposure to heat) acting upon any particles of copper which may happen to lie upon the gilded surface. Lastly, some artists think that they give an additional lustre to their gilt work, by dipping it in a liquor prepared by boiling some yellow materials, as sulphur, orpiment, or turmeric. The only advantage of this operation is, that part of the yellow matter remains in some of the hollows of the carved work, in which the gilding is apt to be more imperfect, and to which it gives a rich and solid appearance. It may here be noticed, that the use of the aquafortis or nitric acid, mentioned in the beginning of the process, is not, as is generally supposed, confined merely to cleansing the surface of the metal to be gilt from rust or tarnish; but it also greatly facilitates the application of the amalgam to the surface of that metal, probably in the following manner: It first dissolves part of the mercury of the amalgam; and when the solution is applied to the copper, this latter metal, having a stronger disposition to unite with the nitrous acid than the mercury has, precipitates the mercury upon its surface, in the same manner as a polished piece of iron precipitates upon its surface copper from a solution of blue vitriol. When the metal to be gilt is thus covered with a thin coat of precipitated mercury, it readily receives the amalgam. On the subject of gilding by amalgamation, Dr. Lewis has the following remarks: "There are two principal inconveniences in this business; one, that the workmen are exposed to the fumes of the mercury, and generally, sooner or later, have their health greatly impaired by them; the other, the loss of the mercury; for though part of it is said to be detained in the cavities made in the chimneys for that purpose, yet the greatest part of it is lost. From some trials I have made, it appeared that both these inconveniences, particularly the first and most considerable one, might be in a good measure avoided, by means of a furnace of a due construction. If the communication of a furnace with its chimney, instead of being over the fire, is made under the grate, the ash-pit door, or other apertures beneath the grate, closed, and the mouth of the furnace left open, the current of air, which otherwise would have entered beneath, enters now at the top, and passing down through the grate to the chimney, carries with it completely both the vapour of the fuel, and the fumes of such matters as are placed upon it. The back part of the furnace should be raised a little higher above the fire than the fore-

part, and an iron plate laid over it, that the air may enter only at the front, where the workmen stands, who will be thus effectually secured from the fumes, and from being incommoded by the heat, and at the same time have full liberty of introducing, inspecting, and removing, the work. If such a furnace is made of strong forged (not milled) iron plate, it will be sufficiently durable. The upper end of the chimney may reach above a foot and a half higher than the level of the fire; over this is to be placed a larger tube, leaving an interval of an inch, or more, all round between it and the chimney, and reaching to the height of ten or twelve feet; the higher the better. The external air, passing up between the chimney and the outer pipe, prevents the latter from being much heated, so that the mercurial fumes will condense against its sides into running quicksilver, which falling down to the bottom, is there caught in a hollow rim, formed by turning inwards a portion of the lower part, and conveyed by a pipe at one side into a proper receiver.

GILDING IRON OR STEEL. In gilding iron or steel by means of an amalgam, as the metal has no affinity for the mercury, an agent must be employed to dispose the surface to receive the gilding. For this purpose a solution of mercury in nitrous acid (aqua fortis), or what the workmen call quicksilver-water, is applied to the parts intended to be gilded; the acid, by a stronger affinity, seizes on a portion of the iron, and deposits in the place of it a thin coating of mercury, which will not refuse an union afterwards with the gold amalgam that may be applied; but by this process the surface of the metal is injured by the nitrous acid, and the union of the mercury is very slight, so that a bright and durable gilding cannot be obtained.—*Another method.* Sometimes a solution of blue vitriol is applied, with a camel's-hair pencil, to the parts of the steel intended to be gilt. By a chemical action, exactly similar to what we have described as taking place when a solution of nitrate of mercury is employed, a thin coating of copper is precipitated on the metal. Copper having an affinity for mercury, a kind of union may by this means be effected between the amalgam and the iron or steel, as the case may be. In whichever of these methods the amalgam is brought into union with the steel, the surface is injured by the action of the acid employed, and still a heat sufficient to volatilize the mercury must be afterwards used.

GILDING OF IRON BY HEAT. When the surface is polished bright, it must be heated till it becomes blue. Gold leaf is then applied to its surface, and burnished down. It is then heated again, and another layer of gold burnished on it. In this manner three or four coats are given, according to the strength of the gilding intended. This is a more laborious process than the two last, but it is not attended with so much risk.

GILDING IRON OR STEEL, AN IMPROVED PROCESS FOR. This process, which is less known among artists than it deserves to be, may prove useful to those who have occasion to gild iron or steel. The first part of the process consists in pouring over a solution of gold in nitro-muriatic acid (aqua regia) about twice as much ether, which must be done with caution, and in a large vessel. These liquids must then be shaken together; as soon as the mixture is at rest, the ether will be seen to separate itself from the nitro-muriatic acid, and to float on the surface. The nitro-muriatic acid becomes more transparent, and the other darker than they were before; the reason of which is, that the ether has taken the gold from the acid. The whole mixture is then to be poured into a glass-funnel, the lower aperture of which is small; but this aperture must not be opened till the fluids have completely separated themselves from each other. It is then to be opened; by which means the liquid which has taken the lowest place by its greater

gravity, viz. the nitro-muriatic acid, will run off; after which, the aperture is to be shut, and the funnel will then be found to contain nothing but ether mixed with the gold, which is to be put into well-closed bottles, and preserved for use. In order to gild iron or steel, the metal must be first well polished with the finest emery, or rather with the finest crocus martis or colcothar of vitriol, and common brandy. The auriferous ether is then to be applied with a small brush; the ether soon evaporates, and the gold remains on the surface of the metal. The metal may then be put into the fire, and afterwards polished. By means of this auriferous ether, all kinds of figures may be delineated on iron, by employing a pen, or fine brush. It is in this manner, we believe, that the Solinger sabre-blades are gilded. Instead of ether, the essential oils may be used, such as oil of turpentine, or oil of lavender, which will also take gold from its solution.

GILDING OF SILVER. Dissolve gold in the nitro-muriatic acid, and dip some linen rags in the solution; then burn them, and carefully preserve the ashes, which will be very black, and heavier than common. When any thing is to be gilded, it must be previously well burnished; a piece of cork is then to be dipped, first into a solution of salt in water, and afterwards into the black powder; and the piece, after being rubbed with it, must be burnished. This powder is frequently used for gilding delicate articles of silver.

GILDING OF BRASS AND COPPER. Fine instruments of brass, in order that their surface may be kept longer clean, may be gilded in the following manner. Provide a saturated solution of gold, and having evaporated it to the consistence of oil, suffer it to shoot into crystals. These crystals must then be dissolved in pure water, and the articles to be gilded being immersed in it, are then to be washed in pure water, and afterwards burnished. This process may be repeated several times, till the articles have been well gilt. A solution of gold-crystals is preferred to a mere solution of gold, because in the latter there is always a portion of free acid, which will not fail to exercise more or less action on the surface of the brass or copper, and injure its polish.

GRECIAN GILDING. Dissolve some mercury in muriatic acid (spirit of salt), which will give a muriate of mercury. Mix equal parts of this and sal ammoniac, and dissolve them in aqua fortis. Put some gold into this, and it will dissolve. When this is applied to silver, it becomes black; but by heating, it assumes the appearance of gilding.

GOLD, TO MAKE SHELL. Grind up gold-leaf with honey in a mortar; then wash away the honey with water, and mix the gold-powder with gum-water. This may be applied to any article with a camel's-hair pencil, in the same way as any other colour.

GLASS, TO GILD. Take an equal quantity of chalk and red-lead, grind them together, and temper with lint-seed-oil; lay it on, and when almost dry, lay the gold-leaf on, let it dry, and then polish it.

TO GILD PAPER. Grind bole-armoniac with rain-water, and give one laying of it; when it is dry, take glair of eggs, and add to it a little sugar-candy and gum-water, which lay over the former, and upon this, when it is dry enough, lay leaf-silver, or leaf-gold.

TO GILD THE LEAVES OF BOOKS. Take bole-armoniac, eight penny-weights; sugar-candy, two penny-weights: mix and grind them with glair of eggs; then on a bound book (while it is in the press, after it hath been smeared with glair of eggs, and is dried) smear the said composition, let it dry, then rub it well and polish it; then with fair water wet the edges of the book, and suddenly lay on the gold, press it down gently with cotton, let it dry, and then polish it with a tooth.

GILES, Sr. the tutelar saint of Edinburgh, a native of Greece, who flourished in the sixth century, and was descended of an illustrious family. On the death of his parents he gave all his estate to the poor; and travelled into France, where he retired into a wilderness near the conflux of the Rhone with the sea, and con-

tinued there three years. Having obtained the reputation of extraordinary sanctity, various miracles were attributed to him; and he founded a monastery in Languedec, known long after by the name of St. Giles's. In the reign of James II. Mr. Preston of Gorton, whose descendants still possess an estate in the country of Edinburgh,

Edinburgh, got possession of an arm of this saint; which relic he bequeathed to the church of Edinburgh. In gratitude for this donation, the magistrates granted a charter in favour of Mr. Preston's heirs, by which the nearest heir of the name of Preston was entitled to carry it in all processions. They also obliged themselves to found an altar in the church of St. Giles's, and appoint a chaplain for celebrating an annual mass for the soul of Mr. Preston; and likewise, that a tablet containing his arms, and an account of his pious donation, should be put up in the chapel.

GILGAL, in ancient geography, a place between Jericho and Jordan, noted for the first encampment of the Israelites on this side Jordan, about a mile from Jericho. It sometimes also denotes Galilee. Joshua xii. 23.

GILL, JOHN, D. D. a Protestant dissenting minister of the Baptist denomination, the son of Edward Gill, a deacon of the Baptist church at Kettering, in Northamptonshire, was born at Kettering, Nov. 23, 1697. He was early sent to a grammar-school in the neighbourhood; where he very soon surpassed boys much his seniors. Besides going through the common school-books, he read most of the Latin classics, and made great proficiency in the Greek language. He was put to the business of his father, but so far improved his leisure-hours, as to be able, before he was 19, to read all the Greek and Latin authors that fell in his way. He studied logic, rhetoric, moral and natural philosophy; and learnt the Hebrew language so as to read it with ease, without any other assistance than Buxtorf's grammar and lexicon. Neither the pursuit of learning, however, nor his other necessary avocations, could eradicate those religious impressions received in early life. About 1716 he became a preacher, and officiated to a congregation of Higham Ferrers, from whence in 1719 he removed to London, where he was chosen pastor of the Baptist congregation in Southwark. He died in 1721. The university of Aberdeen conferred on him the degree of doctor in divinity. In his sentiments, he was a Calvinist of the most rigid cast. His works are, 1. A Commentary on the Old and New Testament, in 9 vols. fol. 2. A Body of Divinity in 3 vols. 4to. 3. The Cause of God and Truth, 4 vols. 8vo. 4. A Treatise concerning the Prophecies of the Old Testament respecting the Messiah. 5. A Dissertation on the Antiquity of the Hebrew Language, Letters, Vowel-Points, and Accents. 6. Sermons on the Canticles, folio; besides a great number of sermons and controversial pieces on different subjects.

GILL, a measure of capacity, containing a quarter of a pint.

GILLYFLOWER. See **DIANTHUS**.

GILOLO, a large island of the Pacific Ocean, one of the Moluccas, lying between 1° Lat. S. and 2° Lat. N. and between 125° and 128° Lon. E.

GILPIN, BERNARD, an eminent English divine, descended from an ancient and honourable family in Westmoreland, and born in 1517. Being bred in the Roman Catholic religion, he for some time defended it, and at Oxford held a disputation with Hooper, afterwards bishop of Worcester, and martyr for the Protestant faith; but was engaged in another disputation with Peter Martyr, and began seriously to examine the contested points. Being presented to the vicarage of Norton in Durham, he resigned it, and went abroad to consult eminent professors on both sides: and after three years absence returned a little before the death of Queen Mary I. satisfied in the doctrines of the reformation. He was kindly received by his uncle Dr. Tonstall, bishop of Durham; who soon after gave him the archdeaconry of Durham, and rectory of Effington. Though the persecution was then at its height, he boldly preached against the vices, errors, and corruptions, of the times, especially in the clergy; on which a charge consisting of 13 articles was drawn up against him, and presented in form to the bishop. But Dr. Tonstall dismissed the cause in such a manner as to protect his nephew, without endangering himself, and soon after presented him to the rich living of Houghton le Spring. He was again accused to the bishop, and again protected; when his enemies, enraged at this second defeat, laid their complaint before Dr. Bonner, bishop of London; who immediately gave orders to apprehend him. Upon which Mr. Gilpin bravely prepared for martyrdom; and ordering his steward to provide him a long garment that he might make a decent appearance at the stake, set out for London. Providentially, however, he broke his leg on the journey; which protracted his arrival until the queen's death. Being im-

mediately set at liberty, he returned to Houghton, where he was received by his parishioners with the sincerest joy. Upon the deprivation of the Popish bishops, he was offered the see of Carlisle, which he declined; and confining his attention to his rectory, discharged all the duties of his function in the most exemplary manner. He was not satisfied with the advice he gave in public, but used to instruct in private; and made his parishioners come to him with their difficulties. His kindness towards the poor was extraordinary, and he was most forward to assist those who had large families. In the distant parishes where he preached, as well as in his own neighbourhood, his generosity and benevolence were continually exercised: particularly in the desolate parts of Northumberland. "When he began his journey," says an old MS. life of him, "he would have 10l. in his purse; and, at his coming home, he would be 20 nobles in debt, which he would always pay within a fortnight after." In the gaols he visited, he was not only careful to give the prisoners proper instructions, but used to purchase for them likewise what necessities they wanted. Even upon the public road, he never let slip an opportunity of doing good. He has often been known to take off his cloak, and give it to an half-naked traveller; and when he has had scarce money enough in his pocket to provide himself a dinner, yet would he give away part of that little, or the whole, if he found any who seemed to stand in need of it. This excellent divine, who deservedly obtained the glorious titles of the Father of the Poor, and the Apostle of the North, died in 1583, in the 66th year of his age.

GILT VARNISH. See **VARNISH**.

GIMBALS, in sea-affairs, the brass-rings by which a sea-compass is suspended in its box, so as to counteract the effect of the ship's motion, and keep the card horizontal.

GIMBETING, a term applied to the anchor to denote the action of turning it round by the stock, so that the motion of the stock appears similar to that of the handle of a gimblet when it is employed.

GIN, in mechanics, a machine for driving piles, fitted with a windlass and winches at each end, where eight or nine men heave; and round which a rope is reeved that goes over the wheel at the top; one end of this rope is seized to an iron-monkey, that hooks to a beetle of different weights, according to the piles they are to drive, from being eight to thirteen hundred weight; and when hove up to the cross-piece, near the wheel, it unhooks the monkey, and lets the beetle fall on the upper end of the pile, and forces the same into the ground: then the monkey's own weight overhauls the windlass, in order for its being hooked again to the beetle.

GIN. See **GENEVA**.

GINANNIA, in botany, a genus of the enneandria monogynia class and order. Natural order, Lomentaceæ. Calyx double, both one-leaved; petals three, fringed, spreading; germ pedicelled, with a membranaceous wing at top; legume. There is but one species, viz. *G. guianensis*, a shrub about fifteen feet high; a native of the forests of Guiana.

GINGEN, an imperial town of Suabia, 16 miles of Ulm. Lon. 10. 13. E. Lat. 48. 39. N.

GINGER. See **AMOMUM**.

GINGER-WINE is made as follows: take three gallons of water, two ounces of rance-ginger, and three pounds of sugar; boil them for an hour, and then put into it three lemons, and a little good yeast; close up the vessel, and let it stand five days: if it has so worked as to be clear in that time, it may be bottled; if not, let it stand longer, until it has worked sufficiently; and in ten days after it may be drank.

GINORA, in botany, a genus of the monogynia order, and decandria class of plants. Calyx cleft into six parts; petals six capsule unilocular, quadrivalved, coloured, and polyspermous.

GINSENG, in botany. See **PANAX**.

GIODDA, or **GEDDAH**, a sea-port of Arabia, on the E. coast of the Red Sea. Lon. 39. 27. E. Lat. 21. 30. N.

GIOVENAZZO, a town and fort of Naples, in the province of Bari, 11 miles E. S. E. of Trani.

GIRDERS, in architecture, some of the largest pieces of timber in a floor. Their ends are usually fastened into summers and breast-summers, and joists are framed in at one end to the girders. The size of girders and summers, upon the rebuilding of London, were ordained by act of parliament, to be in length from ten to

twenty-six feet, in breadth from eleven to seventeen inches, and in depth from eight to fourteen inches.

GIRDING-GIRT, in the sea-language. A ship is girt, or hath a girding-girt, when her cable being so tight, or strained, upon the turning of the tide, she cannot get over it, but lies across the tide.

GIRDLE, [*cingulus* or *zona*, Lat.] in antiquity, a belt or band of leather, or other matter, tied about the reins to keep that part more firm and tight. It was anciently the custom for bankrupts and other insolvent debtors to put off and surrender their girdle in open court. The reason was, that our ancestors used to carry all their necessary utensils, as purse, keys, &c. tied to the girdle; whence the girdle became a symbol of the estate.

GIRGE, a town of Egypt, capital of Said.

GIRGENTI, a town of Sicily, which occupies part of the site of the ancient Agrigentum, 47 miles S. of Palermo.

GIRON, St. a town of France, on the Sarat, in the department of Arriege, and late province of Couserans, three miles S. of St. Liser.

GIRONDE, a department of France, containing part of the late province of Guienne. Bourdeaux is the capital.

GIRONDE, a river of France, which is formed by the union of the Garonne and Dordogne, three miles N. of Bourdeaux, and runs through the above department into the Atlantic, after a course of twenty-seven miles N. N. W.

GIRONDE, a town of France, in the department of the same name, four miles and a half W. of Reolle.

GIRONNE, or **GIRONNY**, in heraldry, a coat of arms divided into girones, or triangular figures, meeting in the centre of the shield, and alternately colour and metal.

GISBORN, a town in the West Riding of Yorkshire, thirty-seven miles S. E. of Manchester.

GISBOROUGH, a town of England, in the N. Riding of Yorkshire, eleven miles E. of Stockton.

GISEXIA, in botany, a genus of the pentandria pentagynia class and order. Natural order, Succulentæ. Calyx five-leaved; corolla none; capsule five, approximating, roundish, one-seeded. There is but one species, viz. *G. pharnacioides*, trailing *Gisekia*, an annual plant, and a native of the East Indies.

GITI, a town of Asia, in Thibet, 234 miles N. N. E. of Delhi. Lon. 79. 36. E. Lat. 32. 10. N.

GITTITH, a Hebrew word occurring frequently in the Psalms, and generally translated wine-presses. Some think it signifies a sort of musical instrument; others, that the psalms with this title were sung after the vintage; and others, that the hymns of this kind were invented in the city of Gath.

GIVEN, among mathematicians and philosophers, the same with data. If a magnitude be known, or we can find another equal to it, it is said to be given in magnitude. Or when the position of any thing is known, it is said to be given in position: when the diameter or radius of a circle is known, the circle is given in magnitude. The circle is given in position, when the position of the centre is given. See DATA.

GIULA, a strong town of Upper Hungary, near Transylvania, thirty miles N. W. of Arad.

GIUSTANDEL, or **GIUSTENDIL**, a large and strong town of European Turkey, in Macedonia, sixty miles S. E. of Durazzo.

GLABRARIA, in botany, a genus of the polyadelphia polyanthia class and order. Calyx five-cleft; petals five; nectary composed of bristles the length of the calyx; stamens thirty, always in sixes; pericarpium a drupe. There is but one species, viz. *G. tersa*, a large tree resembling the camphor-tree, the wood of which is very light and pale-coloured, and not being liable to rot, or to be injured by insects, it is much used for building both houses and ships. It is a native of the East-Indies.

GLACIERS, a name given to some very extensive fields of ice among the Alps. Mr Coxé says, that these mountains, in general, are composed of many parallel chains, the highest of which occupy the centre, and the others gradually diminish as we recede from thence. The central chain appears covered with pointed rocks; all parts of which, that are not absolutely perpendicular, lie hid under perpetual snow and ice. On each side of this ridge are fertile and cultivated valleys, interspersed with numerous villages, and watered by numerous streams. The elevated peaks of the central chain are covered with snow: but their declivities, excepting

those that are extremely steep, have all a covering of ice as well as snow; the intermediate parts being filled with vast fields of ice, terminating in the cultivated valleys. The same phenomena, though on a smaller scale, occur in those chains that are at a distance from the principal one: in those which are most remote, no ice, and scarcely any snow, is observed, unless upon some of the most elevated summits; and the mountains diminishing in height and ruggedness, appear covered with verdure, until at last they terminate in small hills and plains. Thus the glaciers may be divided into two sorts; the first occupying the deep valleys in the bosom of the Alps, called ice-valleys; the second covering the declivities and sides of the mountains. These are called by Mr. Coxé, the Upper and Lower Glaciers.

GLACIS, in building, an easy insensible slope or declivity. The descent of the glacis is less steep than that of the talus. In gardening, a descent sometimes begins in talus, and ends in glacis. The glacis of the corniche is an easy imperceptible slope in the cymatium, to promote the descent and for draining off the rain-water.

GLACIS, in fortification, that mass of earth which serves as a parapet to the covered way, sloping easily towards the champaign, or field. See FORTIFICATION.

GLADIATORS, in antiquity, were persons who fought, generally in the arena at Rome, for the entertainment of the people. They were usually slaves, and fought out of necessity; though sometimes freemen adopted the profession, like our prize-fighters, for a livelihood. The Romans borrowed this cruel diversion from the Asiatics: some suppose out of policy, the frequent combats of gladiators tending to accustom the people to despise dangers and death. From the earliest times with which we have any acquaintance in profane history, it had been the custom to sacrifice captives or prisoners of war, to the manes of the great men who had died in the engagement: thus Achilles, in the Iliad, lib. xxiii. sacrifices twelve young Trojans to the manes of Patroclus; and in Virgil, lib. xi. ver. 81, Æneas sends captives to Evander, to be sacrificed at the funeral of his son Pallas. In course of time they came also to sacrifice slaves at the funerals of all persons of condition: this was even esteemed a necessary part of the ceremony: but as it would have appeared barbarous to have massacred them like beasts, they were appointed to fight with each other, and endeavoured to save their own lives by killing their adversary. This seemed somewhat less inhuman, because there was a possibility of avoiding death, by an exertion of skill and courage. This occasioned the profession of gladiator to become an art: hence arose masters of the art, and men learned to fight and exercise it. These masters, whom the Latins called Lanistæ, bought young slaves to be trained up to this cruel trade, whom they afterwards sold to such as had occasion to present the people with so horrible a show. These exhibitions were at first performed near the sepulchre of the deceased, or about the funeral-pile; but were afterwards removed to the circus and amphitheatres, and became ordinary amusements. The first show of gladiators, called munus gladiatorum, was exhibited at Rome, according to Valerius Maximus, by M. and D. Brutus, upon the death of their father, A. U. C. 490. On this occasion there were probably only three pair of gladiators. In 537, the three sons of M. Æmilius Lepidus the augur, who had been three times consul, entertained the people with the cruel pleasure of seeing twenty-two gladiators fight in the forum. The ædiles, prætors, consuls, and, above all, the candidates for offices, made their court to the people, by entertaining them frequently with these fights; and the priests were sometimes the exhibitors of the barbarous shows. Suetonius mentions the ludi pontificales, August, cap. 44, and Pliny, the ludi sacerdotales, Epist. lib. vii. As for the emperors, to ingratiate themselves with the populace, they humoured them with combats of gladiators almost upon all occasions; and as these increased, the number of combatants increased likewise. Accordingly, Julius Cæsar, in his ædileship, diverted the people with 320 couple. These sports were become so common, and their consequences in a variety of respects so dangerous, that Cicero preferred a law, that no person should exhibit a show of gladiators within two years before he appeared candidate for any office. Julius Cæsar ordered, that only a certain number of men of this profession should be in Rome at a time; Augustus decreed, that only two shows of gladiators should be presented in a year, and never above sixty couple of combatants in a show; and Tiberius provided by an order of the senate, that no person should

have

have the privilege of gratifying the people with such a solemnity, unless he was worth 400,000 sesterces. They were also considerably regulated by Nerva. Claudius restrained them to certain occasions; but he soon after annulled his decree, and private persons began to exhibit them at pleasure as usual. Some carried the brutal satisfaction so far as to have them at their ordinary feasts. And not slaves only, but other persons, would hire themselves to this infamous office. The master of the gladiators made them all first swear that they would fight to death; and if they failed, they were put to death either by fire, or swords, clubs, whips, or the like. It was a crime for the wretches to complain when they were wounded, or to ask for death or seek to avoid it when overcome; but it was usual for the emperor to grant them life when they gave no signs of fear, but waited the fatal stroke with courage and intrepidity. Augustus even decreed that it should always be granted them. From slaves and freed men the inhuman sport at length spread to people of rank and condition; so that Augustus was obliged to issue a public edict that none of the senatorian order should become gladiators; and soon after he laid the same restraint on the knights: nevertheless, Nero is said to have brought upwards of 400 senators and 600 Roman knights upon the arena; though Lipsius takes both these numbers to be falsified, and reduces them to forty senators and sixty knights: yet Domitian, that other monster of cruelty, refined upon Nero, exhibiting combats of women in the night-time. Constantine the Great is said to have first prohibited the combats of gladiators in the East. Some time before the day of combat, the person who presented the people with the shows gave them notice thereof by programmes or bills, containing the names of the gladiators, and the marks whereby they were to be distinguished: for each had his several badge; which was most commonly a peacock's feather, as appears from the scholiast of Juvenal on the 158th verse of the third satire, and Turnebus *Advers. lib. ii. cap. 8*. They also gave notice how long the shows would last, and how many couples of gladiators there were; and it appears, from the fifty-second verse of the seventh satire of the second book of Horace, that they sometimes made representations of these things in painting, as is practised among us by those who have any thing to shew at fairs. The day being come, they began the entertainment by bringing two kinds of weapons; the first were staves or wooden files, called *rudes*; and the second were effective weapons, as swords, poniards, &c. The first were called *arma lusoria*, or *exercitoria*; the second *decretoria*, as being given by decree or sentence of the prætor, or of him at whose expence the spectacle was exhibited. They began to fence or skirmish with the first, which was to be the prelude to the battle; and from these, when well warmed, at the sound of the trumpets they advanced to the second with which they fought naked. Then they were said *vertere arma*. The terms of striking were *petere et repetere*; of avoiding a blow, *exire*; and when one of the combatants received a remarkable wound, his adversary or the people cried out, *Habet* or *Hoc habet*. The first part of the engagement was called *ventilare*, *præludere*; and the second, *dimicare ad certum*, or *versis armis pugnare*: and some authors think, with much probability, that it is to these two kinds of combat that St. Paul alludes in the passage, 1 Cor. ix. 26, 27, "I fight, not as one that beateth the air; but I keep my body under, and bring it into subjection." If the vanquished surrendered his arms, it was not in the victor's power to grant him life. The people during the time of the republic, and the prince or people during the time of the empire, were alone empowered to grant it. The reward of the conqueror was a branch of palm-tree, and a sum of money, probably collected among the spectators: sometimes they gave him his congé, or dismissed him by putting one of the wooden files or *rudes* in his hand; and sometimes they even gave him his freedom, putting the pileus on his head. The sign or indication, whereby, the spectators shewed that they granted the favour, was *premere pollicem*, which M. Dacier takes to be a clenching of the fingers of both hands between one another, and so holding the two thumbs upright close together; and, when they would have the combat finished, and the vanquished slain, *verterunt pollicem*, they bent back the thumb; which we learn from Juvenal, *Sat. iii. ver. 36*. The gladiators challenged or defied each other, by shewing the little finger; and, by extending this, or some other, during the combat, they owned themselves vanquished, and begged mercy from the people: *Victi ostensam digiti veniam a populo postulabant*, says the old scholiast on Per-

sus. There were various kinds of gladiators, distinguished by their weapons, manner, and time of fighting, &c. as, the *andabata*, mentioned under *Andabata*: the *estervarii*, who always fought in troops or companies, number against number; or, according to others, who fought promiscuously, without any certain order: the *dimacha*, who fought armed with two poniards or swords, or with sword and dagger: the *essedarii*, who fought in cars: the *fiscales*, or *Casariani*, who belonged to the emperor's company; and who, being more robust and dexterous than the rest, were frequently called for; and therefore named also *postulatii*. Several other kinds are mentioned in the ancient authors.

GLADIATORS' WAR, [*bellum Gladiatorum*, or *Spartacum*,] called also the *Servile War*, was a war which the Romans sustained about A. U. C. 680. Spartacus, Crinus, and Oenomaus, having escaped, with other gladiators to the number of seventy-four, out of the place where they had been kept at Capua, gathered together a body of slaves, put themselves at their head, rendered themselves masters of all Campania, and gained several victories over the Roman prætors. At length they were defeated in 682, at the extremity of Italy; having, in vain, attempted to pass over into Sicily. Thus war proved very formidable to the Romans. Cassius was not able to finish it: Pompey the Great was forced to be sent as general.

GLADIATOR, THE DYING, a most valuable monument of ancient sculpture, long preserved in the palace of Chigi, but carried to Paris with the *Laocoon*, &c. in 1796. This gladiator after having received the mortal stroke, appears particularly careful at procumbat honeste, "that he might fall honourably." He is seated in a reclining posture on the ground, and seems to have just strength sufficient to support himself on his right arm; and in his expiring moments he does not abandon himself to grief and dejection; but is solicitous to maintain that firmness of aspect and attitude, which the gladiators valued themselves on preserving in this last scene of distress. He betrays no tokens of fear by his countenance, nor sheds one tear. *Quis mediocris gladiator ingemuit? quis vultum mutavit unquam? Quis non modo stetit, verum etiam decubuit turpiter?* says Cicero, in that part of his *Tusculan*, where he is describing the astonishing firmness of those persons. He appears, notwithstanding his remaining strength, to have but a few moments to live. Thus the ancients knew how to animate marble, and to give it almost every expression of life.

GLADIOLUS, CORN-FLAG: a genus of the monogynia order, and triandria class of plants; natural order, *Ensateæ*. Corolla sex-partite, ringent; stamina ascending and bending upwards. There are thirty species. The plants are very hardy, and will thrive in any soil or situation. They are propagated by offsets from the roots.

GLAIRE, [*glær*, Saxon, amber; *glar*, Danish, glass; *glairé*, Fr. *glareux*, Lat.] the white of an egg. It is used as a varnish for preserving paintings. For this purpose it is beat to an unctuous consistence, and commonly mixed with a little brandy or spirit of wine, to make it work more freely, and with a lump of sugar to give it body and prevent its cracking: and then spread over the picture or painting with a brush.

GLAMORGANSHIRE, a county of South Wales, said to have derived its name from a contraction of the Welsh words *Gwalld Morgan*, "the country of Morgan," and supposed to have been thus called from a prince of this part of the country, said to have been killed eight hundred years before the birth of our Saviour. Others derive the name from the British word *mor*, which signifies the sea; this being a maritime county. It is bounded on the south and part of the west by the Bristol channel; on the north-west by Caermarthenshire; on the north by Brecknockshire; and on the east by Monmouthshire. It is 48 miles long from E. to W. 27 broad from N. to S. and 116 in circumference. The principal rivers of this county are the Rhymny, the Taff, the Ogmore, the Avon, the Cleddagh, and the Tawe. The air, in the south part, towards the sea, is temperate; but the north part, which is mountainous, is cold and piercing, full of thick woods, extremely barren, and thin of inhabitants. The mountains, however, feed herds of cattle, and send forth streams which add greatly to the fertility of the other parts of the county: they have likewise coal and lead ore. The south part is remarkably fertile.

GLAMOUR, or **GLAMER**, an old term of popular superstition in Scotland, denoting a kind of magical mist believed to be raised

raised by sorcerers, and which deluded their spectators with visions of things which had no real existence, altered the appearance of those which really did exist, &c.

GLANCE, in mineralogy, one of the ores of cobalt, found in beds of mica, in Sweden: its colour is tin-white; it is massive in various forms, and crystallized in cubes and octahedrons; the surface of the crystals is smooth and splendid: it is brittle, and the specific gravity is 6.45.

GLANDS. See **ANATOMY**.

GLANDERS. See **FARRIERY**.

GLANDORE, a town of Ireland, in Cork, with an excellent harbour, 3 miles W. of Ross.

GLANS. See **ANATOMY**.

GLANVIL, **JOSEPH**, a learned and ingenious, but fanciful and credulous, writer, in the seventeenth century born at Plymouth in 1636, and bred at Oxford. He was a great admirer of Mr. Baxter, and zealous for a commonwealth. After the restoration, he published *The Vanity of Dogmatizing*; was chosen F. R. S. and, taking orders in 1662, was present to the vicarage of Frome-Selwood in Somersetshire. In 1662, he published his *Lux Orientalis*; in 1665, his *Scep sis Scientifica*; and in 1666, *Some Philosophical Considerations touching the Being of Witches and Witchcraft*. In 1668, he published *Plus Ultra*; or, *The progress and Advancement of Knowledge since the Days of Aristotle*. He likewise published *A seasonable Recommendation and Defence of Reason*; and *Philosophia Pia*, or *A Discourse of the Religious Temper and Tendencies of Experimental Philosophy*. In 1678 he was made a prebendary of Worcester, and died in 1680.

GLAREOLA, the **PRATINCOLE**, a genus of birds of the order grallæ. Bill strong, straight, short, hooked at the end; nostrils at the base linear and oblique: feet four-toed; toes long, slender, connected at the base by a membrane: tail forked, consisting of twelve feathers. There are three species, of which the principal is *P. austriaca*; this is about as large as a blackbird, lives on water-insects and on worms; is found in great numbers on the banks of the Rhine. See **PLATE LVIII**.

GLARIS, or **GLARUS**, one of the cantons of Switzerland,

bounded on the E. by the country of the Grisons, and partly by that of Sargans. It is a mountainous country, almost entirely surrounded by the Alps.

GLARIS, or **GLARUS**, a city of the Helvetic republic, capital of the above canton, thirty-two miles E. of Lucerne.

GLASGOW, a large and beautiful city of Scotland in Lanarkshire, on the N. bank of the Clyde, justly esteemed the second in that part of the united kingdom. Glasgow lies ten miles S. E. of Dunbarton, and forty-four W. of Edinburgh.

GLASS, a solid, transparent, brittle, substance, produced by melting together sand, flint, alkaline salts, &c. It is derived by some from the Latin word *glastum*, the name of a plant called by the Greeks *λαστις*, by the Romans *vitrum*; by the ancient Britons *guadum*, and by the English *wood*. We find frequent mention of this plant in ancient writers, particularly Cæsar, Vitruvius, Pliny, &c. who relate, that the ancient Britons painted or dyed their bodies with *glastum*, *guadum*, *vitrum*, &c. i. e. with the blue colour procured from this plant. And hence, the name glass, which has always somewhat of this bluishness in it. Good glass is very transparent, and when cold very brittle; but at a red heat it is one of the most ductile bodies known, and may be drawn into threads so very delicate, as to become almost invisible to the human eye. It is extremely elastic, and one of the most sonorous of bodies. See **HARMONICA**. There are but few chemical agents which have any action upon it. Fluoric acid has a great power over it, and dissolves it very quickly (see **FLUORIC ACID**); so also have the fixed alkalies when assisted by heat. The continued action of hot water is said to be capable of decomposing glass, which it is thought will fully explain how the siliceous earth was obtained by Boyle and others, when they subjected water to very tedious distillations in glass-vessels. It has also been supposed, that the deflagration of the oxygen and hydrogen gases, in the formation of water, has decomposed the glass, which will account for an acid as part of the result. Flint-glass melts at the temperature of 10° Wedgewood; crown-glass at 30°; and bottle-glass at 47°. The specific gravity varies between 2.48 and 3.33.

GLASSMAKING.

GLASSMAKING, the art of making glass; or the manufacture of that commodity from its original materials, into any form. Under this article we shall give a brief description, not only of the materials and art of glassmaking, but also of several branches connected with it; such as the grinding, polishing, and colouring of glass. At what period the art of glassmaking was first invented, is altogether uncertain. Some suppose it was invented before the flood; and Neri traces its antiquity at least to the time of Job. But these are mere conjectures; for the word *Zechuchib*, translated crystal, (Job. xxviii. 17.) admits of various significations, and from the context evidently means some precious stone. The Egyptians boast, that this art was taught them by Hermes. Aristophanes, Aristotle, Alexander Aphrodisæus, Lucretius, and St. John the divine, put it out of all doubt that glass was used in their days. Pliny relates, that it was first discovered accidentally in Syria, at the mouth of the river Belus, by certain merchants driven thither by a storm at sea; who being obliged to continue there, and dress their victuals by making a fire on the ground, where there was great plenty of the herb kali; that plant, burning to ashes; its salts mixed and incorporated with the sand, or stones fit for vitrification, and thus produced glass; and that, this accident being known, the people of Sidon in that neighbourhood essayed the work, and brought glass into use; since which time the art has been continually improving. Be this as it may, the first glass-houses mentioned in history were erected in Tyre, where the only staple of the manufacture was for many ages. The sand which lay on the shore for about half a mile round the mouth of the Belus was peculiarly adapted to the making of glass; and the wide range of the Tyrian commerce gave an ample vent for the productions of the furnace. The first time we hear of glass made among the Romans was in the reign of Tiberius, when Pliny relates that an artist had his

house demolished for making glass malleable, or rather flexible; though Petronius Arbitr and others assure us, that the emperor ordered the artist to be beheaded for his invention. It is certain that a plate of glass was found at Herculaneum, which was destroyed, A. D. 80; and that glass-vessels were made at Rome under Nero. The earliest mention made of glass-windows, is by Lactantius in the third century. Before the conquest of Britain by the Romans, glass-houses had been erected in this island, as well as in Gaul, Spain, and Italy. Hence, in many parts of the country are to be found annulets of glass, having a narrow perforation and thick rim, denominated by the remaining Britons *gleineu naid-reedh*, or glass-adders, and which were probably in former times used as amulets by the druids. It can scarcely be doubted, that the Britons were sufficiently well versed in the manufacture of glass, to form out of it many more useful instruments than glass-beads. According to Bede, artificers skilled in making glass for windows were brought over into England in 674, by abbot Benedict, who were employed in glazing the church and monastery of Weremouth. According to others, they were first brought over by Wilfrid, bishop of Worcester, about the same time. Till this time the art of making glass for windows was unknown in Britain; and glass-windows did not begin to be common before 1180. Italy had them first; next France, from whence they came to England. Venice, for many years, excelled all Europe in the fineness of its glasses; and in the thirteenth century, the Venetians were the only people that had the secret of making crystal looking-glasses. The glass-manufacture was first begun in England in 1557; the finer sort was made at Crutched Friars, in London; the fine flint-glass, little inferior to that of Venice, was first made in the Savoy House, in the Strand, London. This manufacture appears to have been much improved in 1635, when it was carried on with pit-coal instead of wood;

wood; and a monopoly was granted to Sir Robert Mansell, who was allowed to import the fine Venetian flint-glasses for drinking, the art of making which was not brought to perfection before the reign of William III. The first glass-plates, for looking-glasses and coach-windows, were made in 1673, at Lambeth, by the encouragement of the duke of Buckingham; who, in 1670, introduced the manufacture of fine glass into England, by Venetian artists, with amazing success. So that within the last century, the French and English have not only equalled, but even excelled, the Venetians, and are now no longer supplied from abroad. The French made a considerable improvement in the art of glass, by the invention of a method to cast very large plates, till then unknown, and scarce practised yet by any but themselves and the English. This branch was established in Lancashire in 1773, and is now very flourishing.

OF THE MATERIALS FOR MAKING GLASS.

The materials, whereof glass is made, are salt and sand, or stones.

I. The salt is procured from a sort of ashes brought from the *Levant*, called *polverine*, or *rochetta*. They are the ashes of a water-plant named *kali*, see *SALSOLA*, cut down in summer, dried in the sun, and burnt in heaps, either on the ground, or on iron-grates; the ashes falling into a pit, grow into a hard mass, or stone, fit for use. It may also be procured from common kelp, or the ashes of the *fucus vesiculosus*. See *FUCUS*. To extract the salt, these ashes are powdered and sifted, then put into boiling water, and there kept till one-third of the water be consumed; the whole being stirred up from time to time, that the ashes may incorporate with the fluid, and all its salts be extracted: then the vessel is filled up with new water, and boiled over again, till one-half be consumed; what remains is a sort of ley, strongly impregnated with salt. This ley, boiled over again in fresh coppers, thickens in about twenty-four hours, and shoots its salt; which is to be ladled out, as it shoots, into earthen pans, and thence into wooden vats to drain and dry. This done, it is grossly pounded, and thus put into a sort of oven, called *calcar*, to dry. There are also other plants which yield a salt fit for glass; such as the common thistle, bramble, hops, wormwood, woad, tobacco, fern, and the whole leguminous tribe, as pease, beans, &c. Pearl-ashes form a leading flux in the manufacture of glass, and mostly supply the place of the *Levant* ashes, the *barillas* of Spain, and other kinds, formerly imported for making both glass and soap. There are other fluxes used for different kinds of glass, and for various purposes, as calcined lead, nitre, sea-salt, borax, arsenic, smiths-clinkers, and wood-ashes, containing the earth and lixivate salts as produced by incineration. With regard to these several fluxes, we may observe, in general, that the more calx of lead, or other metallic earth, that enters into the composition of any glass, so much the more fusible, soft, coloured, and dense; this glass is, and reciprocally. The colours given to glass, by calxes of lead, are shades of yellow: on the other hand, glasses that contain only saline fluxes partake of the properties of salts; they are less heavy, less dense, harder, whiter, more brilliant, and more brittle, than the former; and glasses containing both saline and metallic fluxes also partake of the properties of both these substances. Glasses too saline are easily susceptible of alteration by the action of air and water: especially those in which alkali prevail; and these are also liable to be injured by acids. Those that contain too much borax and arsenic, though at first they appear very beautiful, quickly tarnish and become opaque when exposed to air. By attending to these properties of different fluxes, the artist may adjust the proportions of these to sand, or powdered flints, for the various kinds of glass.

II. The sand or stone, called by the artists *tarso*, is the second ingredient in glass, and that which gives it the body and firmness. These stones, *Agricola* observes, must be such as will fuse; and of these such as are white and transparent are best; so that crystal has the precedency of all others. At Venice they chiefly use a sort of pebble, found in the *Tesino*, resembling white marble, and called *cuogolo*. Indeed *Ant. Neri* assures us, that all stones, which will strike fire with steel, are fit to vitrify: but *Dr. Morret* shews, that there are some exceptions from this rule. Flints are admirable; and when calcined, powdered, and searced, make a pure white crystalline metal: but the expence of preparing them makes the masters of our glass-houses sparing of their use. Where proper stones cannot be so conveniently had, sand is used. The

VOL. II.—NO. 97.

best for this purpose is that which is white, small, and shining; examined by the microscope, it appears to be small fragments of rock-crystal. For green glass, that which is of a soft texture, and more gritty; it is to be well washed, which is all the preparation it needs. Our glass-houses are furnished with white sand, for their crystal-glasses, from *Lynn* in Norfolk, and *Maidstone* in Kent, and with the coarser, for green glass, from *Woolwich*.

OF THE FURNACES AND IMPLEMENTS USED IN GLASSMAKING.

In this manufacture there are three sorts of furnaces; the first, called *calcar*, is for the frit; second for working the glass; the third, for annealing it, is called the *leer*. See Plate LXXXIV.

I. The *CALCAR* is an oven ten feet long, seven feet broad, and two deep: the fuel, which in Britain is sea-coal, is put into a trench on one side of the furnace; and the flame, reverberating from the roof upon the frit, calcines it.

II. The *GLASS-FURNACE*, or *WORKING-FURNACE*, is round, of three yards diameter, and two high, or in that proportion. It is divided into three parts, each of which is vaulted. The lower part is properly called the crown, and is made in that form. Its use is to keep a brisk fire, which is never put out. The mouth is called the *bocca*. There are several holes in the arch of this crown, through which the flame passes into the second partition, and reverberates into the pots filled with the materials. Round the insides there are eight or more pots placed, and piling pots on them. The number of pots is always double that of the boccas or mouths, or of the number of workmen, that each may have one pot refined to work out of, and another for metal to refine in, while he works out of the other. Through the working-holes the metal is taken out of the pots, and the pots are put into the furnace; and these holes are stopped with moveable covers made of lute and brick, to screen the workman's eyes from the scorching flames. On each side of the *boeca* or mouth is a *boccarella* or little hole, out of which coloured glass or finer metal is taken from the piling-pot.

III. Above this oven there is the third oven, called the *LEER*, about five or six yards long, and four feet wide, where the vessels of glass are annealed or cooled. This part consists of a tower, besides the leer, into which the flame ascends from the furnace. The tower has two mouths, through which the glasses are put in with a fork, and set on the floor or bottom: but they are drawn out on iron pans, called *fraches*, through the leer, to cool by degrees; so that they are quite cool by the time they reach the mouth of the leer, which enters the *sarosel* or room where the glasses are to be stowed.

IV. The *FURNACE FOR THE GREEN GLASS* is square; and at each angle it has an arch for annealing or cooling glasses. The metal is wrought on two opposite sides, and on the other two they have their colours, into which are made linnen-holes for the fire to come from the furnace to bake the frit, and to discharge the smoke. Fires are made in the arches to anneal the work, so that the whole process is done in one furnace. These furnaces must not be of brick, but of hard sandy stones. In France, they build the outside of brick; and the inner, to bear the fire, is made of a sort of fullers earth, or tobacco-pipe clay, of which they also make the melting-pots. In Britain the pots are made of *Sturbridge* clay. *Mr. Blancourt* observes, that the worst and roughest work in this art is the changing the pots when they are worn out or cracked. In this case, the great working-hole must be uncovered; the faulty pot must be taken out with iron hooks and forks, and a new one must be speedily put in its place, through the flames, by the hands only. For this work, the man guards himself with a garment made of skins, in the shape of a pantaloon, that covers him all but his eyes, and is made as wet as possible: the eyes are defended with a proper sort of glass. The principal implements used by the glass-blower are, a blowing-pipe, fig. 3, which is an iron pipe about two feet long, with rope-yarn wrapped round it at A, where the workman takes hold of it; two or three iron rods, fig. 4, of the same length; a pair of blunt shears, fig. 5; and several different sized ladles, shovels, pokers, &c.

OF THE DIFFERENT KINDS OF GLASS.

The manufactured glass now in use may be divided into three general kinds; 1. white transparent glass; 2. coloured glass; and 3. common green, or bottle-glass. Of the first kind there is a great

great variety; as the flint-glass, and the German crystal-glass, which are applied to the same uses: the glass for plates, for mirrors, or looking-glasses; the glass for windows and other lights; and the glass for phials and small vessels. And these, again differ in the substances employed as fluxes in forming them, as well as in the coarseness or fineness of such as are used for their body. The flint and crystal, mirror and best, window-glass, not only require such purity in the fluxes, as may render it practicable to free the glass perfectly from all colour; but, for the same reason, either the white Lynn sand, calcined flints, or white pebbles, should be used. The others do not demand the same nicety in the choice of the materials; though the second kind of window-glass, and the best kind of phial, will not be so clear as they ought, if either too brown sand, or impure salts, be suffered to enter into their composition. Of coloured glass there is also a great variety of sorts, differing in their colour or other properties according to the occasions for which they are wanted: These differences depend on the preparation and management of the artists by whom they are manufactured. Glass is also distinguished into three principal kinds, by the form or manner of working it; viz. 1. Round glass, as that of our bottles, vessels, phials, drinking-glasses, &c. 2. Table or window-glass, of which there are divers kinds: as crown-glass, jealous-glass, &c. And 3. Plate-glass, or mirror-glass.

OF THE COMPOSITIONS FOR MAKING BOTTLE AND PHIAL-GLASS.

I. THE COMMON-BOTTLE, or GREEN GLASS, is formed of sand of any kind, fluxed by the ashes of burnt wood, or of any parts of vegetables; to which may be added the scorie or clinkers of forges. When the softest sand is used, 200lb. of wood-ashes will suffice for 100lb. of sand, which are to be ground and mixed together. The composition with the clinkers consists of 170lb. of wood-ashes, 100lb. of sand, and 50 of clinkers, which are to be ground and mixed together. If the clinkers cannot be ground, they must be broken into small pieces, and mixed with the other matter without grinding.

II. PHIAL-GLASS is a kind betwixt the flint-glass and the bottle-glass. The best kind may be prepared with 120lb. of white sand, 50lb. of unpurified pearl-ashes, 10lb. of common salt, 5lb. of arsenic, and 5 oz. of magnesia. The composition for green or common phial-glass consists of 120lb. of the cheapest white sand, 80lb. of wood-ashes well burnt and sifted, 20lb. of pearl-ashes, 15lb. of common salt, and 1lb. of arsenic.

OF THE COMPOSITIONS FOR MAKING WHITE GLASS AND CRYSTAL.

Take of the whitest tarso, pounded small, and seared as fine as flour, 200lb. of the salt of polverine 130lb. mix them, and put them into the calcar, first heating it. For an hour keep a moderate fire, and keep stirring the materials with a proper rake, that they may incorporate and calcine together; then increase the fire for five hours; after which take out the matter; which being now sufficiently calcined, is called FRIT, or BOLLITO. See these articles. From the calcar put the frit in a dry place, and cover it up from the dust for three or four months. To make the white glass or crystal, take of the crystal frit, set it in pots in the furnace, adding to it a due quantity of manganese: when the two are fused, cast the fluor into fair water, to clear it of the salt called sandiver; which would otherwise make the crystal obscure and cloudy. This lotion must be repeated again and again, as often as needful, till the crystal be fully purged; or the scum may be taken off by proper ladles. Then set it to boil four, five, or six days; which done, see whether it have manganese enough; and if it be yet greenish, add more by little and little at a time, taking care not to overdose it, because the manganese inclines it to a blackish hue. Then let the metal clarify, till it becomes of a clear and shining colour; which done, it is fit to be blown or formed into vessels.

FLINT-GLASS, as it is called by us, is of the same general kind with that which in other places is called crystal-glass. It has this name from being originally made with calcined flints, before the use of the white sand was understood; and retains the name, though no flints are now used in the composition of it. This flint-glass differs from the other, in having lead for its flux, and white sand for its body; whereas the fluxes used for the crystal-glass are salts or arsenic, and the body consists of calcined flints or white river-pebbles, tarso, or such stones. To the white sand and lead a pro-

per proportion of nitre is added, and a small quantity of magnesia, or manganese. In some works they use a proportional quantity of arsenic to aid the fluxing ingredients. The most perfect kind of flint-glass may be made, by fusing with a very strong fire 120lb. of the white sand, 50lb. of red lead, 40lb. of the best pearl-ashes, 20lb. of nitre, and 5oz. of magnesia. Another composition of flint-glass, which is said to come nearer to the kind now made, is the following: 130lb. of sand, 54lb. of the best pearl-ashes, 36lb. of red-lead, 12lb. of nitre, and 6oz. of magnesia. To either of these a pound or two of arsenic may be added, to increase the flux of the composition. A cheaper composition may be made with 120lb. of white sand, 35lb. of the best pearl-ashes, 40lb. of red lead, 13lb. of nitre, 6lb. of arsenic, and 4oz. of magnesia; or instead of the arsenic may be substituted 15lb. of common salt; but this will be more brittle. The cheapest composition for the worst kind of flint-glass consists of 120lb. of white sand, 30lb. of red lead, 20lb. of the best pearl-ashes, 10lb. of nitre, 15lb. of common salt, and 6lb. of arsenic. The best German crystal is made of 120lb. of calcined flints or white sand, 70lb. of the best pearl-ashes, 10lb. of saltpetre, 2lb. of arsenic, and 5oz. of magnesia. And a cheaper composition is formed of 120lb. of calcined flints or white sand, 46lb. of pearl-ashes, 7lb. of nitre, 6lb. of arsenic, and 5oz. of magnesia. A glass much harder than any prepared in the common way, may be made by means of borax, thus: Take 4oz. of borax, and one of fine sand; reduce both to a subtil powder, and melt them together in a large close crucible set in a wind-furnace, keeping up a strong fire for half an hour; then take out the crucible, and when cold break it, and there will be found at the bottom a pure hard glass, capable of cutting common-glass like a diamond. This experiment, duly varied, says Dr. Shaw, may lead to several useful improvements in making glass-enamels, and factitious gems; and shews an expeditious method of making glass, without any fixed alkali, which has been generally thought an essential ingredient in glass; and perhaps calcined crystal, or other substances, added to this salt instead of sand, might make a glass approaching to the nature of a diamond.

OF THE COMPOSITIONS FOR MAKING PLATE OR MIRROR-GLASS.

The materials of which this glass is made are much the same as those of other works of glass, viz. an alkaline salt and sand. The salt, however, should not be that extracted from the ashes of the Syrian kali, but that from barilla, growing about Alicante in Spain. It is very rare that we have the barilla pure; the Spaniards in burning the herb mix another herb with it, which alters its quality; or add sand to it to increase the weight, which is easily discovered, if the addition be only made after the boiling of the ashes, but next to impossible if made in the boiling. From this adulteration threads and other defects in plate-glass arise. To prepare the salt, clean it well of all foreign matters; pound or grind it with a kind of mill, and finally sift it pretty fine. Pearl-ashes properly purified, will furnish the alkaline salt requisite for this purpose; but it will be necessary to add borax or common salt, to facilitate the fusion, and prevent the glass from stiffening in that degree of heat in which it is to be wrought into plates. To purify the pearl-ashes, dissolve them in four times their weight of boiling water, in a pot of cast iron, kept clean from rust. Let the solution be removed into a clean tub, and remain there 24 hours or longer. Having decanted the clear part of the fluid from the sediment, put it again in the iron pot, and evaporate the water till the salts are left perfectly dry. Preserve them in stone-jars, well secured from air and moisture. Pearl-ashes may also be purified in the highest degree, so as to be proper for the manufacture of the most transparent glass, by pulverizing 3lb. of the best kind with 6oz. of saltpetre in a glass or marble mortar, till they are well mixed; and then putting part of the mixture into a large crucible, and exposing it in a furnace to a strong heat. When this is red-hot, throw in the rest gradually; and when the whole is red-hot, pour it out on a moistened stone or marble, and put it into an earthen or clean iron pot, with ten pints of water; heat it over the fire till the salts be entirely melted; let it then stand to cool, and filter it through paper in a pewter cullender. When filtered, put the fluid again into the pot, and evaporate the salt to dryness, which will then be as white as snow. As to the sand, sift and wash it till the water come off very clear; and when it is well dried, mix it with the salt, passing the mixture through another sieve. This done, lay them in the annealing furnace for about two hours; in which time the matter be-

comes

comes very light and white. In this state they are called frit, and are laid up in a dry clean place, for at least a year, to give them time to incorporate. When they employ this frit, they lay it for some hours in the furnace, adding to some the fragments of old and ill made glasses; taking care first to calcine them by heating them red-hot in the furnace, and thus casting them into cold water. To the mixture must likewise be added manganese, to promote the fusion and purification. The best composition for looking-glass-plates consists of 60lb. of white sand cleansed, 25lb. of purified pearl-ashes, 15lb. of saltpetre, and 7lb. of borax. If a yellow tinge should affect the glass, a small portion of magnesia, mixed with an equal quantity of arsenic, should be added. An ounce of the magnesia may be first tried; and if this prove insufficient, the quantity should be increased. A cheaper composition consists of 60lb. of white sand, 20lb. of pearl-ashes, 10lb. of common salt, 7lb. of nitre, 2lb. of arsenic, and 1lb. of borax.

METHOD OF WORKING OR BLOWING GLASS.

The working-furnace for round glass, fig. 1, has six boccas or apertures: at one of these called the great bocca, the furnace is heated, and the pots of frit are at this set in the furnace; two other smaller holes, called boccarellas, serve to lade or take out the melted metal, at the end of an iron, to work the glass. For explaining the operation, we shall describe the method of making a goblet. The workman dips the end D of his blowing-pipe, fig. 3, which is hot, through the working-hole of the furnace, fig. 1, into the melting-pot, which contains the glass in a state of fusion; and by turning it about, a small quantity of the glass, which is called metal, sticks to the iron: this he repeats three or four times (between each dip rolling it on an iron plate, fixed on the stool, fig. 8, to bring it into form) till he has got metal enough: he then blows at the end B of the pipe, which expands the metal into a hollow globular form; and then by swinging it round his head, it lengthens out in the shape of a bladder. The workman then sits down on the stool, fig. 7, between the two bars H and I, across which he lays the blowing-iron, and rolls it along under his left hand, following it at the same time with the shears, fig. 5, in his right hand, the blades *nn* of which embrace it, and by gently putting them in the proper place, he brings the glass into the form shewn in fig. 11; meanwhile, the boy who attends him brings a lump of metal from the furnace on the end of one of the iron rods fig. 4, which he sticks on the bottom, or part *a*, fig. 11, and by twisting the rod round, he separates the metal from the rod, and leaves it on the glass-vessel; the workman then rolls the rod and vessel as before, and with his shears, as shewn in fig. 10, brings the lump of glass into the form of a stem and foot, as there described. The boy then holds the tool, fig. 6, against the bottom of the foot, *b*, while it is turning, to flatten it. The boy next takes another iron-rod, fig. 4, and gets a very small piece of metal on its end: this he applies to the centre of the bottom of the foot, so as to connect it to the rod; when the workman, by touching it at the neck *a* with a wet iron, cracks the glass, so that a slight blow upon the rod with the hand will separate it at *d*, from the blowing-pipe M. The glass has by this time become too cold to work without heating again, which is done at the furnace; the workman then returns to the stool, fig. 7, and again rolls the rod round with his left hand as before, and with the point of one of the blades *n* of the shears opens the end *d*, fig. 9, of the glass; after which he inserts both points, and finally works it into the form of fig. 14. It is now separated from the rod N, and is carried on a shovel like a baker's peel by the boy to the annealing furnace, or oven in the upper part of the furnace, where it remains in a low red-heat for many hours, by which its former extreme brittleness is removed. Window-glass is made in a similar manner, except that the liquid mass at the end of the tube is formed into a cylindrical shape, which being cut longitudinally by scissors or shears, is gradually bent back until it becomes a flat plate.

CASTING OR RUNNING OF LARGE MIRROR-GLASS-PLATES.

The furnace is of a very large dimension, environed with several ovens, or annealing furnaces, called carquoises, besides others for the making of frit and calcining of old pieces of glass. Fig. 2, A represents the bocca, or mouth of the furnace; B the cistern that conveys the liquid glass it receives out of the melting-pots in the furnace to the casting-table. These cisterns are filled in the fur-

nace, and remain therein six hours after they are filled; and then are hooked out by a large iron chain, guided by a pulley, placed upon a carriage with four wheels, (marked C,) by two men. This carriage has no middle-piece; so that when it has brought the cistern to the casting-table, D, they slip off the bottom of the cistern, and out rushes a torrent of flaming matter upon the table: this matter is confined to certain dimensions by the iron rulers EE, which are moveable, and retain it, and determine the width of the glass; while a man, with the roller F, resting on the edge of the iron rulers, reduces it as it cools to an equal thickness, which is done in the space of a minute. This table is supported on a wooden frame, with trustles for the convenience of moving to the annealing-furnace; into which, strewed with sand, the new plate is shoved, where it will harden in about ten days. What is most surprising throughout the whole of this operation, is the quickness and address wherewith such massy cisterns, filled with a flaming matter, are taken out of the furnace, conveyed to the table, and poured therein, the glass spread, &c. The whole is inconceivable to such as have not been eye-witnesses of that surprising manufacture. As fast as the cisterns are emptied, they carry them back to the furnace and take fresh ones, which they empty as before. This they continue to do so long as there are any full cisterns; laying as many plates in each carquoise as it will hold, and stopping them up with doors of baked earth, and every chink with cement, as soon as they are full, to let them anneal, and cool again, which requires about 14 days.

OF THE ORNAMENTING, GRINDING, AND POLISHING, OF GLASS.

Good glass-ware is often ornamented by the glass-cutter before it is offered for sale (see fig. 13:) this is generally performed by a machine, fig. 15, wherein AA is a large wheel to be turned by a man at the winch B. The band of this wheel passes round a pulley *a* on the axle of a wheel or cutter C, and thereby turns it with a great velocity: beneath the cutter a cistern D is placed, and above it a small cask E to contain water, the cock *b* of which is so placed and adjusted as to drop very slowly on the circumference of the cutter. The glass-grinder sits down on the stool F, and after dressing the edge of the cutter with emery paste, he applies successively the parts of the glass which are to be cut, as shewn in fig. 12, and dexterously moves the glass, as the parts intended to be cut are sufficiently ground away: after this another similar cutter is applied instead of C, or the same is dressed with finer emery paste, or mixture of tripoli and other polishing powders, in order to polish the parts which have been cut; such parts as are intended to have a white appearance are left rough. The cutters C are formed of hard wood or soft metal, and the workman is provided with several, of different sizes and thicknesses, particularly at the edge, according to the device which is to be cut on the glass. It is by the fine edge of these cutters that letters, flowers, &c. are cut on glasses by dexterous workmen. Plate or mirror-glass is ground, and polished, in order to give it the fine lustre which is requisite for mirrors. The workmen lay it horizontally upon a flat stone-table made of a fine-grained free-stone; and for its greater security they plaster it down with lime or stucco; else the force of the workmen, or the motion of the wheel with which they grind it, would move it about. This stone-table is supported by a strong frame A, fig. 16, made of wood; with a ledge quite round its edges, rising about two inches higher than the glass. Upon this glass to be ground is laid another rough glass not above half so big, and so loose as to slide upon it; but cemented to a wooden plank, to guard it from the injury it must otherwise receive from the scraping of the wheel to which this plank is fastened, and from the weights laid upon it to promote the grinding or triture of the glasses. The whole is covered with a wheel, B, made of hard light wood, about six inches in diameter, by the pulling of which backwards and forwards alternately, and sometimes turning it round, the workmen, who always stand opposite to each other, produce a constant attrition between the two glasses, and bring them to what degree of smoothness they please, by first pouring in water and coarse sand; after that, a finer sort of sand, as the work advances, till at last they pour in the powder of smalt. As the upper or incumbent glass polishes and grows smoother, it is taken away, and another from time to time put in its place. This engine is called a mill by the artists, and is used only for the largest glasses; for in the grinding of the less

less glasses, they work without a wheel, and have only four wooden handles fastened to the four corners of the stone that loads the upper plank, by which they work it about. When the grinder, (who finds it very difficult to bring the glass to an exact plainness,) has done his utmost, it is turned over to the polisher; who with the fine powder, of tripoli stone, or emery, brings it to a perfect evenness and lustre. The instrument used in this branch is a board, *c c*, furnished with a felt, and a small roller, which the workman moves by means of a double handle at both ends. The artist, in working this roller, is assisted with a wooden hoop or spring to the end of which it is fixed: for the spring, by constantly bringing the roller back to the same points, facilitates the action of the workman's arm.

COLOURING OF GLASS.

Glass is often tinged of various colours, which is performed by mixing with it, while in fusion, some one of the metallic oxides. Thus blue glass is formed by the oxide of cobalt; green by the oxide of iron, or copper; violet by the oxide of manganese; red by a mixture of the oxides of copper and iron; purple by the oxide of gold; white by the oxide of arsenic and zinc; and yellow by the oxide of silver, and by combustible bodies.

PAINTING ON GLASS.

A few years since, Mr. Farrant obtained a patent for painting, spangling, gilding, and silvering glass, which was performed on the back of the crystal or glass, so as when finished to appear on the front: the colours prepared in oil or varnish as in other works. The parts of ornament which are gold must be first shadowed on the glass, and when dry the gold-leaf must be laid on. Silver-ornament is to be done in the same manner. For the spangling, leave the parts to be spangled to the last: then shadow them, and when dry varnish the parts with copal varnish, and strew the spangles on while it is wet; when they are dry, varnish them two or three times. The ancient manner of painting in glass was very simple, and consequently very easy: it consisted in the mere arrangement of pieces of glass of different colours in some sort of symmetry, and constituted what is now called mosaic work. In process of time they came to attempt more regular designs, and also to represent figures heightened with all their shades: yet they proceeded no farther than the contours of the figures in black with water-colours, and hatching the draperies after the same manner on glasses of the colour of the object they designed to paint. For the carnation, they used glass of a bright-red colour, and upon this they drew the principal lineaments of the face, &c. with black. But in time, the taste for this sort of painting improving considerably, and the art being found applicable to the adorning of churches, &c. they found out means of incorporating the colours in the glass itself, by heating them in the fire to a proper degree, having first laid on the colours. The colours used in the painting or staining of glass are very different from those in painting either in water or oil colours. For black, take scales of iron one ounce, scales of copper one ounce, jet half an ounce; reduce them to powder, and mix them. For blue, take powder of blue one pound, sal nitri half a pound; mix them, and grind them well together. For carnation, take red chalk eight ounces, iron scales and litharge of silver of each two ounces, gum-arabic half an ounce; dissolve in water; grind all together for half an hour as stiff as you can; then put it in a glass and stir it well, and let it stand to settle fourteen days. For green, take red lead one pound, scales of copper one pound, and flint five pounds; divide them into three parts, and add to them as much nitre; put them into a crucible, and melt them with a strong fire; and when it is cold, powder it, and grind it to a porphyry. For gold-colour, take silver an ounce, antimony half an ounce; melt them in a crucible; then pound the mass to powder, and grind it on a copper-plate; add to it yellow ochre, or brick-dust calcined again, 15 ounces, and grind them well together with water. For purple, take minium one pound, brown stone one pound, white flint five pounds; divide them into three parts, and add to them as much nitre as one of these parts; calcine, melt, and grind, it as you did the green. For red, jet four ounces, litharge of silver two ounces, red chalk one ounce; powder them fine, and mix them. For white, take jet two parts, white flint, ground on glass very fine, one part, mix them. For yellow, take Spanish brown ten parts, leaf-silver one part, antimony half a part; put all into a crucible,

and calcine them well. In the windows of ancient churches, &c. there are to be seen the most beautiful and vivid colours imaginable, which far exceed any of those used by the moderns, not so much because the secret of making those colours is entirely lost, as that the moderns will not go to the charge of them, nor be at the necessary pains. Those beautiful works which were made in the glass-houses were of two kinds. In some, the colour was diffused through the whole substance of the glass. In others, which were the more common, the colour was only on one side, scarcely penetrating within the substance above one-third of a line; though this was more or less according to the nature of the colour, the yellow being always found to enter the deepest. These last, though not so strong and beautiful as the former, were of more advantage to the workmen, since on the same glass, though already coloured, they could shew other kind of colours where there was occasion to embroider draperies, enrich them with foliage, or represent other ornaments of gold, silver, &c. In order to this, they made use of emery, grinding or wearing down the surface of the glass, till they were got through the colour to the clear glass. This done, they applied the proper colours on the other side of the glass. By this means, the new colours were hindered from running and mixing with the former, when they exposed the glasses to the fire, as will appear hereafter. When, indeed, the ornaments were to appear white, the glass was only bared of its colour with emery, without tinging the place with any colour at all; and this was the manner by which they wrought their lights and heightenings on all kinds of colour. The first thing to be done in order to paint or stain glass in the modern way, is to design and even colour the whole subject on paper. They then choose such pieces of glass as are clear, even, and smooth, and proper to receive the several parts, and proceed to distribute the design itself, or papers it is drawn on, into pieces suitable to those of the glass; always taking care that the glasses may join in the contours of the figures and the folds of the draperies, that the carnations and other finer parts may not be impaired by the lead with which the pieces are to be joined together. The distribution being made, they mark all the glasses as well as papers, that they may be known again; which done, applying every part of the design upon the glass intended for it, they copy or transfer the design upon this glass with the black colour diluted in gum-water, by tracing and following all the lines and strokes as they appear through the glass with the point of a pencil. When these strokes are well dried, which will happen in about two days, the work being only in black and white, they give a slight wash over with urine, gum-arabic, and a little black, and repeat it several times, according as the shades are desired to be heightened, with this precaution, never to apply a new wash till the former is sufficiently dried. This done, the lights and risings are given by rubbing off the colour in the places with a wooden point, or the handle of the pencil. As to the other colours above-mentioned, they are used with gum-water, much as in painting in miniature, taking care to apply them lightly for fear of effacing the outlines of the design; or even, for the greater security, to apply them on the other side; especially yellow, which is very pernicious to the other colours, by blending with them. And here too, as in pieces of black and white, particular regard must always be had not to lay colour on colour, or lay on a new lay till such times as the former are well dried. It may be added, that the yellow is the only colour that penetrates through the glass, and incorporates with it by the fire; the rest, and particularly the blue, which is very difficult to use, remaining on the surface, or at least entering very little. When the painting of all the pieces is finished, they are carried to the furnace or oven, to anneal or bake the colours. The furnace here used is small, built of brick, from 18 to 30 inches square; at six inches from the bottom is an aperture to put in the fuel, and maintain the fire. Over this aperture is a grate, made of three square bars of iron, which traverse the furnace, and divide it into two parts. Two inches above this partition is another little aperture, through which they take out pieces to examine how the coction goes forward. On the grate is placed a square earthen pan, six or seven inches deep, and five or six inches less every way than the perimeter of the furnace. On the one side is a little aperture, through which to make trials, placed directly opposite to that of the furnaces destined for the same end. In this pan are the pieces of glass to be placed in the following manner: First, the bottom of the pan is covered with three strata or layers, of quick-lime pulverized;

pulverized; those strata being separated by two others of old broken glass, the design of which is to secure the painted glass from the too intense heat of the fire. This done, the glasses are laid horizontally on the last or uppermost layer of lime. The first row of glass they cover over with a layer of the same powder, an inch deep; and over this they lay another range of glasses, and thus alternately till the pan is quite full, taking care that the whole heap always end with a layer of the lime-powder. The pan being thus prepared, they cover up the furnace with tiles, on a square table of earthenware, closely luted all round, only leaving five little apertures, one at each corner, and another in the middle, to serve as chimneys. Things thus disposed, there remains nothing but to give the fire to the work. The fire for the first two hours must be very moderate, and must be increased in proportion as the

coction advances, for the space of ten or twelve hours, in which time it is usually completed. At last the fire, which at first was charcoal, is to be of dry-wood, so that the flame covers the whole pan, and even issues out at the chimneys. During the last hours, they make essays, from time to time, by taking out pieces laid for the purpose through the little aperture of the furnace and pan, to see whether the yellow is perfect, and the other colours in good order. When the annealing is thought sufficient, they proceed with great haste to extinguish the fire, which otherwise would soon burn the colours, and break the glasses. By several statutes, regulations are made for making, importing, and exporting glass, which is to be under the management of the officers of the customs and excise. See Complete Abridgement of the Excise Laws.

GLASSES OPTICAL. See OPTICS.

GLASSWORT, in botany. See SALSOLA.

GLASTONBURY, a town of England, in Somersetshire, anciently called Avalonia. It is noted for a famous abbey, some magnificent ruins of which still remain. It is five miles S. S. W. of Wells.

GLASTONBURY THORN. See CRATÆGUS.

GLATZ, a county of Bohemia. It has mines of coal, silver, and iron; stone and marble quarries, plenty of cattle, and fine springs of mineral water. Jaspers, topazes, &c. are found in it.

GLATZ, the capital of the above county, 88 miles E. of Prague.

GLAUBER, JOHN RODOLPHUS, a celebrated German chemist, who flourished about 1646. He wrote a great number of treatises on chemistry, some of which have been translated into French. All his works have been collected into a volume, intitled, *Glauberus concentratus*, which has been translated into English, and printed at London in folio, in 1689.

GLAUBER'S-SALT, a chemical composition, which is usually prepared by adding to sea-salt an equal quantity of sulphuric acid diluted with water, distilling off the marine acid, and dissolving and crystallizing the remainder. These salts may also be obtained by mixing four ounces of borax with one ounce and one drachm of oil of vitriol; the whole of which when sublimed, affords what is by chemists called Sedative Salt; and if the remainder be exposed to a strong fire, it will yield Glauber's-salts. They were first prepared by John Rodolphus Glauber; and are of considerable use in medicine as cooling purgatives, when taken in doses from six to twelve drachms. See SODA.

GLAUCOPIS, or the WATTLE-BIRD, a genus of birds of the order Pica. Bill incurvate and arched; lower mandible shorter than the upper, and carunculate beneath at the base; nostrils depressed, half covered with a cartilaginous membrane; tongue cartilaginous, split and ciliated at the end; legs carinated at the back; feet formed for walking.

G. CINEREA, or CINEREUS WATTLE-BIRD, is about the size of a jay; it is a native of New Zealand.

GLAUCOMA, [from *γλαυκος*, sea-green, or sky-colour,] is a disease of the eyes, wherein the crystalline humour is turned of a bluish or greenish colour, and its transparency hereby diminished. To those whom this disorder is forming, all objects appear as through a cloud or mist; when entirely formed, the visual rays are all intercepted and nothing is seen at all. It is incurable, when inveterate, and in aged persons; and is always very difficult of cure, externals proving of little service. The internals best suited to it, are those used in the gutta serena.

GLAUCUS, in ancient mythology, a deity of the sea, who, before his deification, was a fisherman of Anthedon. Having one day taken a considerable number of fishes, which he laid upon the bank, he perceived that as soon as they touched an herb that grew on the shore, they received new strength, and leaped again into the sea; upon which he was tempted to taste of the herb himself, and instantly leaped into the sea after them, where he was metamorphosed into a Triton, and became one of the sea-gods.

GLAUX, in botany, a genus of the monogynia order, and penicillata class of plants; natural order, Calycanthemæ. Calyx mono-

nophyllous; no corolla; capsule unilocular, quinquevalved, and pentaspermous.

GLAZING, the crusting over of earthenware by a vitreous substance, the basis of which is commonly lead. The Romans had a method of glazing their earthen vessels, which in many respects appears to have been superior to ours. The common brown glazing easily scales off, cracks, and in a short time becomes disagreeable to the eye. Besides, it is very easily destroyed by acids; nor can vessels glazed in this manner be even employed to hold water, without part of it oozing through their pores. Lead is also destructive to the human body; and if acids are unwarily put into vessels glazed with lead, the liquors will receive a very dangerous impregnation from the metal. The Roman glazing, which is yet to be seen upon urns dug up in several places, appears to have been made of some kind of varnish; and Pliny gives us a hint that it was made of bitumen. He tells us, that it never lost its beauty, and that at length it became customary to glaze statutes in this manner. As this varnish sunk deep into the substance of the ware, it was not subject to those cracks and flaws which disfigure our vessels; and as it was not liable to be corroded by acids, it could not be subject to any of the accidents which may ensue from the use of vessels glazed with lead. The usual composition for glazing earthenware is formed of white sand 40lb. of red-lead 20lb. of pearl-ashes 20lb. and of common salt 12lb. Powder the sand by grinding it; then add it to the other ingredients, and grind them together: after which calcine them for some time with a moderate heat, and when the mixture is cold, pound it to powder. When it is to be used, temper it with water. The proportion of these ingredients may be occasionally varied. The ware, after being turned on the wheel and dried in the open air, is covered over with the above composition by a brush; and when set in the furnace the violent heat soon reduces it to a perfect glass, covering the whole internal and external surface of the vessel. Lead, however, ought to be excluded from the composition of glazings, and other fluxes substituted in its stead. A transparent glazing may be prepared without lead, by calcining 40lb. of white sand, 25lb. of pearl-ashes, and 15lb. of common salt; and proceeding as before: and a more perfect transparent glazing may be made of sand, 40lb. of wood-ashes perfectly burnt 50lb. of pearl-ashes 10lb. and of common salt 12lb. The following receipts are mostly from Kunckel, who says, they are the true glazings used at Delft, and the other Dutch manufactories.

1. GLAZING, BLACK. Take eight parts of red-lead, iron-slings three, copper-ashes three, and zaffer two measures. This when melted will make a brown black; and if wanted blacker, add more zaffer to it.

2. GLAZING, BLUE. Take lead-ashes or red lead 1lb. clear sand or powdered flints, 2lb. common salt 2lb. white calcined tartar 1lb. Venice or other glass $\frac{1}{2}$ lb. zaffer $\frac{1}{2}$ lb.; mix them well, and melt them several times, quenching them always in cold water. To have it fine and good, put the mixture into a glass-furnace for a day or two. Another blue glazing may be formed of 1lb. of tartar, $\frac{1}{2}$ lb. of red lead, $\frac{1}{2}$ oz. of zaffer, and $\frac{1}{2}$ lb. of powdered flints, fused or managed as above. Or take 2lb. of calcined lead and tin, and 5lb. of common salt, 5lb. of powdered flints, and

of zaffer, tartar, and Venetian glass, each 1lb. Calcine and fuse the mixture as before. Or, take of red lead one part, of sand three parts, and of zaffer one. For a violet blue glazing, take 4 oz. of tartar, 2 oz. of red lead, 5 oz. of powdered flints, and half a drachm of manganese.

3. **GLAZING, BROWN.** Take red lead and flints, of each 14 parts, and of manganese two parts fused; or, of red lead 12 parts, and manganese one part fused. A brown glazing to be laid on a white ground, may be made of manganese two parts, and of red lead and white glass, of each one part twice fused.

4. **GLAZING, FLESH-COLOURED.** Take 12 parts of lead-ashes, and one of white glass.

5. **GLAZING, GOLD-COLOURED.** Take of litharge three parts, of sand or calcined flint one part; pound and mix these very well together, then run them into a yellow glass with a strong fire. Pound this glass, and grind it into a subtile powder, which moisten with a well saturated solution of silver; make it into a paste, which put into a crucible, and cover it with a cover. Give at first a gentle degree of fire; then increase it, and continue it till you have a glass, which will be green. Pound this glass again, and grind it to a fine powder; moisten this powder with beer, so that it may be applied by a hair-pencil upon the vessels of earthenware. These vessels when covered with this glazing must be first well heated, then put under a muffle; and, as soon as the glass runs, smoked by holding them over burning vegetables; then take out the vessels. Phil. Trans. No. 465. § 6. Kunckel gives several preparations for a gold-coloured yellow glazing. This may be produced by fusing a mixture of three parts of red lead, two of antimony, and one of saffron of Mars; by again melting the powdered mass, and repeating the operation four times, or by fusing four or five times a composition of red lead and antimony of each an ounce, and of scales of iron half an ounce; or by calcining and fusing together eight parts of red lead, and six parts of flints, one part of yellow ochre, one part of antimony, and one part of glass. A transparent gold-coloured glazing may be obtained by twice fusing red lead and white flints, of each 12 parts, and of filings of iron one part.

6. **GLAZING, GREEN.** Take eight parts of litharge or red lead, eight of Venice glass, four of brass-dust or filings of copper; or 10 parts of litharge, 12 of flint or pebble, and one of *as ustum* or copper-ashes. A fine green glazing may be produced by fusing Bohemian granite, filings of copper, red lead, and Venetian glass, in equal proportions; or by fusing white glass, red lead, and filings of copper, one part each; powdering the mass, and adding one part of Bohemian granite to two parts of this powder. A fine green may also be obtained, by mixing and grinding together any of the yellow glazings with equal quantities of the blue glazings; and all the shades and tints of green will be had by varying the proportions of the one to the other, and by the choice of the kind of yellow and blue. For **SEA GREEN**, take 5lb. of lead-ashes, 1lb. of tin-ashes, 3lb. of flint, $\frac{3}{4}$ lb. of salt, $\frac{1}{2}$ lb. of tartar, and $\frac{1}{2}$ lb. of copper-dust.

7. **GLAZING, IRON-COLOURED.** Take 15 parts of lead-ashes or red lead, 14 of white sand or flints, and five of calcined copper. Calcine and fuse this mixture.

8. **GLAZING, LIVER-COLOURED.** Take 12 parts of litharge, eight of salt, six of flint, and one of manganese.

9. **GLAZING, PURPLE BROWN.** Take lead-ashes 15 parts, clean sand or powdered flints 18 parts, manganese one part, and white glass 15; to which some add one of zaffer.

10. **GLAZING, RED.** Take antimony 3lb, litharge or red lead three, and rust of iron one; grind them to a fine powder. Or, take 2lb. of antimony, three of red lead, and one of calcined saffron of Mas; and proceed as before.

11. **GLAZING, WHITE.** For common ware, take 40lb. of clear sand, 75lb. of litharge or lead-ashes, 26 of pot-ashes, and 10 of salt: melt these three times into a cake, quenching it each time in clear cold water. Or, take 50lb. of clean sand, 70 of lead-ashes, 30 of wood-ashes, and 11 of salt. For a fine white: take 2lb. of lead and one of tin; calcine them to ashes: of this take two parts, calcined flint, white sand, or broken white glass, one part, and salt one part; mix them well together and melt them into a cake for use. The trouble of calcining the tin and lead may be prevented by procuring them in a proper state. A very fine white glazing may be obtained by calcining two parts of lead and one part of tin

and taking one part of this mass, and of flints and common salt of each one part, and fusing the mixture. A white glazing may be also prepared by mixing 100lb. of masticot, 60 of red lead, 20 of calcined tin or putty, and 10 of common salt; calcining and powdering the mixture several times.

12. **GLAZING, YELLOW.** Take red lead 3lb. calcined antimony and tin of each 2lb.; or, according to some, equal quantities of the three ingredients. These must be melted into a cake, then ground fine; and this operation repeated several times. Or, take 15 parts of lead ore, three of litharge of silver, and 15 of sand. A fine yellow glazing may be procured by mixing five parts of red lead, two of powdered brick, one of sand, one of white glazing, and two of antimony; calcining the mixture, and then fusing it. Or, take four parts of white glass, one of antimony, three of red lead, and one of iron-scales, and fuse the mixture: or fuse 16 parts of flint, one of iron-filings, and 24 of litharge. A light yellow glazing may be produced with 10 parts of red lead, three of antimony, three of glass, and two of calcined tin. A citron yellow is made of six parts of red lead, seven of fine red brick-dust, and two of antimony. This mixture must be calcined day and night for four days, in the ash-hole of a glass-house furnace, and at last fused.

GLAZING OF DELFT-WARE, PORCELAIN, STONE-WARE, &c. See DELFT, PORCELAIN, and POTTERY.

GLEBE, among miners, signifies a piece of earth in which is contained some mineral ore.

GLEBE, in law, the land belonging to a parish-church, besides the tithes. When a parson or vicar has caused any of his glebelands to be manured and sown, at his own charge, with corn or grain, he may by will devise all the profits and corn growing upon the said glebe; and in case he dies without disposing thereof, his executors shall have the same.

GLECHOMA, **GROUND IVY**; a genus of the gymnospermia order, and didynamia class of plants; natural order, Verticillatae. Calyx five-cleft; each pair of anthers converging in form of a cross. There is but one species, viz. *G. hederacea*, ground-ivy. The leaves are thrown into the vat with ale to clarify it and give it a flavour. Ale thus prepared is often drank as an antiscorbutic. The expressed juice mixed with a little wine, and applied morning and evening, destroys the white specks upon horses eyes. The plants that grow near it do not flourish.

GLEDE, **GLEAD**, or **KITE**. See **FALCO**.

GLEDITSIA, **TRIPLE-THORNED ACACIA**, or **HONEY-LOCUST**; a genus of the dicæa order, and polygamia class of plants; natural order, Lomentaceæ. Hermaphrodite; calyx four-cleft; corolla four-petaled; stamens six; pistil one; legume. There is only one species, with several varieties.

GLEE, in music, a vocal composition in three or more parts, generally consisting of more than one movement, the subject of which may be either gay, tender, or grave; bacchanalian, amatory, or pathetic.

GLEET, in medicine, the flux of thin, limpid humour from the urethra.

GLENDALAGH, an ancient and once celebrated town of Ireland, 5 miles N. W. of Rothdrum, in Wicklow; called also, the Seven Churches.

GLENEGAD HEAD, a cape of Ireland, in Donegal. Lon. 7. 4. W. Lat. 55. 20. N.

GLENSK, a district of Scotland, in Forfarshire, watered by the North Esk.

GLENMORE, [Gael, *i. e.* the great valley,] an extensive district of Murrayshire, in the barony of Kincardine, abounding with wood.

GLINUS, in botany, a genus of the dodecandria pentagynia class and order. Natural order, Coryophyllei. Calyx five-leaved; corolla none; nectaries cloven-bristles; capsule five-cornered, five-celled, five-valved, containing numerous seeds. There are three species.

GLIRES, the name of Linnaeus's fourth order of mammalia. See **ZOOLOGY**.

GLISSON, **FRANCIS**, a learned English physician of the 17th century, who was educated at Cambridge, and was made regius professor of the university. In 1634, he was admitted a fellow of the college of physicians in London. During the civil wars, he practised physic at Colchester, and afterwards settled in London. He greatly improved physic by his anatomical dissections, and made

made several new discoveries of singular use towards establishing a rational practice. He wrote, 1. *De Rachitide*, &c. 2. *De Lympheductis nuper repertis*; with the *Anatomica prolegomena*, & *Anatomia hepatis*. 3. *De Naturæ Substantia energetica*; seu de *Vitæ Naturæ*, ejusque tribus primis Facultatibus, &c. quarto. 4. *Tractatus de Ventrículo & Intestinis*, &c. He discovered the capsule communis, or vagina portæ.

GLOBBA, in botany, a genus of the monogynia order, and monandria class of plants. Corolla equal, trifid; calyx trifid above; capsule trilocular, with many seeds. It has four species.

GLOBE, in geometry. See **MENSURATION**, **GEOMETRY**, and **SPHERE**.

GLOBE, in geography, and astronomy, is particularly used for an artificial sphere of metal, plaster, paper, or other matter; on whose convex surface is drawn a map, or representation either of the earth or heavens, with the several circles conceived thereon. Globes are of two kinds, terrestrial and celestial; each of very considerable use, in astronomy, and geography, for performing many of the operations in these sciences, in any easy obvious manner, so as to be conceived without any knowledge of the mathematical grounds of those arts. The fundamental parts, common to both globes, are an axis, representing that of the world; and a spherical shell, or cover, which makes the body of the globe, on the external surface of which the representation is drawn. See **AXIS**, **POLE**, &c. The description and use of the globes will be found under the article **GEOGRAPHY**, which see.

GLOBES, CONSTRUCTION OF. A wooden axis is provided, somewhat less than the intended diameter of the globe; and into the extremes thereof, two iron-wires are driven for poles: this axis is to be the beam, or basis of the whole structure: On the axis are applied two spherical or rather hemispherical caps, formed on a kind of wooden mould or block. These caps consist of pasteboard, or paper, laid one lay after another, on the mould, to the thickness of a crown-piece; after which, having stood to dry and embody, making an incision along the middle, the two caps thus parted are slipped off the mould. They are next applied on the poles of the axis, as before they were on those of the mould; and to fix them, the two edges are sewed together with pack-thread, &c. The rudiments of the globe thus laid, it must be strengthened and made smooth and regular. In order to this, the two poles are hasped in a metalline semicircle of the size intended; and a kind of plaster, made of whitening, water, and glue, heated, melted, and incorporated together, is daubed all over the paper-surface. In proportion as the plaster is applied, the ball is turned round in the semicircle, the edge whereof pares off whatever is superfluous and beyond the due dimensions, leaving the rest adhering in places that are short of it. After such application of the plaster, the ball stands to dry; which done, it is put again in the semicircle, and fresh matter applied: thus they continue alternately to apply the composition, and dry it, till the ball every where accurately touches the semicircle, in which state it is perfectly smooth, regular, and firm. The ball thus finished, it remains to paste the map, or description thereon; in order to this, the map is projected in several gores, or gussets, all of which join accurately on the spherical surface, and cover the whole ball. To direct the application of these gores, lines are drawn by a semicircle on the surface of the ball, dividing it into a number of equal parts corresponding to those of the gores, and subdividing those again answerably to the lines and divisions of the gores. There remains only to colour and illuminate the globe; and to varnish it, the better to resist dust, moisture, &c. The globe itself thus finished, is hung in a brass-meridian, with an hour-circle, and a quadrant of altitude; and thus fitted into a wooden horizon. In Mr. Chambers's Dictionary, the following method is directed for describing the gores or gussets, "1. From the given diameter of the globe, find a right line AB, fig. 4, Plate LXXV, equal to the circumference of a great circle, and divide it into 12 equal parts. 2. Through the several points of division, 1, 2, 3, 4, &c. with the interval of ten of them, describe arches mutually intersecting each other in D and E; these figures or pieces duly pasted and joined together will make the whole surface of the globe. 3. Divide each part of the right line AB into 30 equal parts, so that the whole line AB, representing the periphery of the equator, may be divided into 360 degrees. 4. From the poles D and E, fig. 5, with the inter-

val of 23 $\frac{1}{2}$ deg. describe arches *ab*; these will be twelfth parts of the polar circles. 5. After the like manner, from the same poles D and E, with the interval of 66 $\frac{1}{2}$ deg. reckoned from the equator, describe arches *cd*; these will be 12th parts of the tropics. 6. Through the degree of the equator *e*, corresponding to the right ascension of any given star, and the poles D and E, draw an arch of a circle; and taking in the compasses the complement of the declination from the pole D, describe an arch intersecting it in *i*; this point *i* will be the place of that star. 7. All the stars of a constellation being thus laid down, the figure of the constellation is to be drawn according to Bayer, Hevelius, or Flamsteed. 8. Lastly, after the same manner are the declinations and right ascensions of each degree of the ecliptic *dg* to be determined. 9. The surface of the globe thus projected on a plane is to be engraven on copper, to save the trouble of doing this over again for each globe. 10. A ball, in the mean time, is to be prepared of paper, plaster, &c. as before directed, and of the intended diameter of the globe; on this, by means of a semicircle and style, is the equator to be drawn; and through every 30th degree a meridian. The ball thus divided into twelve parts, corresponding to the segments before projected, the latter are to be cut from the printed paper, and pasted on the ball. 11. Nothing now remains but to hang the globe as before in a brazen meridian and wooden horizon; to which may be added a quadrant of altitude made of brass, and divided in the same manner as the ecliptic and equator. If the declinations and right ascensions of the stars be not given, but the longitudes and latitudes in lieu thereof, the surface of the globe is to be projected after the same manner as before; except that, in this case, D and E, fig. 5, are the poles of the ecliptic, and *fh* the ecliptic itself; and that the polar circles and tropics, with the equator *g d*, and parallels thereof, are to be determined from their declinations. M. De La Lande, in his *Astronomie*, 1771, Tom. 3. p. 736, relates the following methods: "To construct celestial and terrestrial globes, gores must be engraved, which are a kind of projection, or inclosure of the globe (fig. 6,) similar to what is now to be explained. The length PC of the axis of this curve is equal to a quarter of the circumference of the globe; the intervals of the parallels on the axis PC are all equal, the radii of the circles KDI which represent the parallels are equal to the cotangents of the latitudes, and the arches of each, as DI, are nearly equal to the number of the degrees of the breadth of the gore (which is usually 30°) multiplied by the sine of the latitude: thus, there will be found an intricacy in tracing them; but the difficulty proceeds from the variation found in the trial of the gores when pasting them on the globe, and of the quantity that must be taken from the paper, less on the sides than in the middle; (because the sides are longer) to apply it exactly to the space that it should cover. The method used among workmen to delineate the gores, and which is described by Mr. Bion (*Usage des Globes*, tom. 3,) and by Mr. Robert de Vaugendy in vol. 7th of the *Encyclopædia*, is little geometrical, but yet is sufficient in practice. Draw on the paper a line AC, equal to the chord of 15°, to make the half-breadth of the gore; and a perpendicular PC, equal to three times the chord of 30°, to make the half-length; for these papers, the dimensions of which will be equal to the chords, become equal to the arcs themselves when they are pasted on the globe. Divide the height CP into nine parts, if the parallels are to be drawn in every 10°; divide also the quadrant BE into nine equal parts through each division-point of the quadrant as G; and through the corresponding point D of the right line CP draw the perpendiculars HGF and DF, the meeting of which in F gives one of the points of the curve BEP, which will terminate the circumference of the gore. When a sufficient number of points are thus found, trace the outline RIB with a curved rule. By this construction are given the gore-breadths, which are on the globe, in the ratio of the cosines of the latitudes; supposing these breadths taken perpendicular to CD, which is not very exact, but it is impossible to prescribe a rigid operation sufficient to make a plane which shall cover a curved surface, and that on a right line AB shall make lines PA, PC, PB, equal among themselves, as they ought to be on the globe. To describe the circle KDI which is at 30° from the equator: there must be taken above D a point which shall be distant from it the value of the tangent of 60°, taken out either from the tables, or on a circle equal to the circumference of the globe to be traced; this point will serve as a centre for the parallel

rallel DI, which should pass through the point D, for it is supposed equal to that of a cone circumscribing the globe, and which would touch at the point D. The meridians may be traced to every 10 degrees, by dividing each parallel, as KI, into three parts at the points L and M, and drawing from the pole P, through all these division-points, curves, which represent the intermediate meridians between PA and PB, (as BR and ST, fig. 7.) The ecliptic AF may be described by means of the known declination from different points of the equator that may be found in a table; for 10°, it is 3° 58'; for 20°, 7° 50' as at B; for 30°, 11° 29', &c." It is observed in general, that the paper on which charts are printed, such as the colombier, shortens itself $\frac{1}{2}$ part of a line in six inches upon an average, when it is dried after printing; this inconvenience must therefore be corrected in the engraving of the gores: if notwithstanding that, the gores are found too short, it must be remedied by taking from the surface of the ball a little of the white with which it is covered; thereby making the dimensions suitable to the gore as it was printed. But what is singular is, that in drawing the gore, moistened with the paste to apply it on the globe, the axis GH lengthens, and the side AK shortens, in such a manner, that neither the length of the side ACK, nor that of the axis GEH, of the gore are exactly equal to the quarter of the circumference of the globe, when compared to the figure on the copper, or to the numbered sides shewn in fig. 7. Mr. Bonne having made several experiments on the dimensions that gores take, after they had been parted ready to apply to the globe, and particularly with the paper named *jesus*, that he made use of for a globe of one foot in diameter, found that it was necessary to give to the gores on the copper, the dimensions shewn in fig. 7. Supposing that the radius of the globe contained 720 parts, the half-breadth of the gore is $AG = 188 \frac{1}{5}$, the distance AC for the parallel of 10 degrees taken on the right line IM is 12.81, the small deviation from the parallel of 10 degrees in the middle of the gore ED is 4, the line ABN is right, the radius of the parallel of 10°, or of the circle CEF, is 4083, and so of the others as marked in the figure. The small circular cap which is placed under H, has its radius 253 instead of 247, which it would have if the sine of 26° had been the radius of it.

GLOBES, USES OF THE. See GEOGRAPHY, and ASTRONOMY, with the Plates referred to.

GLOBE-THISTLE. See ECHINOPS.

GLOBULAR CHART, a name given to the representation of the surface, or of some part of the surface of the terrestrial globe upon a plane, wherein the parallels of latitude are circles nearly concentric, the meridian-curves bending towards the poles, and the rhomb-lines are also curves.

GLOBULAR SAILING. See NAVIGATION.

GLOBULARIA, in botany, a genus of the tetrandria monogynia class and order. Natural order, Aggregatae. Calyx common, imbricate; proper, tubular, inferior; corollets the upper lip, two-parted; lower three-parted; receptacle chaffy. There are eight species.

GLOBULE, [*globeule*, French; *globulus*, Latin,] such a small particle of matter as is of a globular or spherical figure; as the red particles of the blood; which swim in a transparent serum, and are easily discovered by the microscope. These will attract one another when they come within a due distance, and unite like the spheres of quicksilver.

GLOGAU, or GLOGAW, a duchy or principality of Silesia, seated on both sides of the Oder, on the borders of Poland.

GLOGAW, GREAT, a strong town of Silesia, the capital of the above duchy, 50 miles N. W. of Breslaw.

GLORIOSA, SUPERB LILY; a genus of the monogynia order, and hexandria class of plants; natural order, Saurmentaceae. Corolla six-petaled, waved, reflex; style oblique. There are two species, viz. *G. superba*, superb lily, and *G. simplex*.

GLOSS, [from the Greek *glossa*, tongue, the office of a gloss being to explain the text, as that of the tongue to discover the mind.] See COMMENTARY.

Gloss is likewise used for a literal translation of a book, into another language word for word.

GLOSSOCOMMON, in mechanics, a name given by Mr. Heron to a machine composed of various dented wheels with pinnions, for raising great weights.

GLOSSOMA, in botany, a genus of the tetrandria monogynia

class and order. Calyx turbinate four-toothed, superior, corolla four-petaled; anthers almost united, with a membranaceous scale at the end; stigmas four, drupe. There is only one species, viz. *G. guianensis*, a native of Guiana.

GLOSSOPETALUM, in botany, a genus of the pentandria pentagynia class and order. Calyx very small, five-toothed; petals five, with a strap at the tip of each; berry. There are two species, both lofty trees, natives of Guiana and Cayenne.

GLOTTIS, in anatomy, the narrow slit at the upper part of the *aspera arteria*, which is covered by the epiglottis when we hold our breath and when we swallow. The glottis, by its dilatation and contraction, modulates the voice. See ANATOMY.

GLOUCESTER, or GLOUCESTERSHIRE, a county of England, bounded on the W. by Monmouthshire, Herefordshire, and the Bristol Channel; on the N. by Worcestershire; on the E. by Oxfordshire and Warwickshire, and on the S. by Wiltshire and Somersetshire. It is 60 miles long from N. E. to S. W. 26 broad, and 160 in circumference. Its manufactures are woollen cloths of various kinds, hats, leather, pens, paper, bar-iron, edge-tools, nails, wire, tinned plates, brass, &c.: and its annual exports, cheese 8000 tons; bacon, grain, cyder, 5000l. worth; perry, fish, 4000l. worth, &c. It lies in the diocese of Gloucester and circuit of Oxford. The air is very wholesome, but the surface is very various. The county is watered by the Severn, Wye, Avon, Isis, Leyden, Frome, Stroud, and Windrush, besides less streams; all abounding with fish. The soil is in general very fertile, though much diversified, yielding plenty of corn, pasture, fruit, and wood.

GLOUCESTER, the capital of the above county, is seated on the E. side of the Severn. It is an ancient city; and by Antoninus is called *Clevum* or *Glevum*, which *Camden* thinks was formed from the British *Caer Glowe*, i. e. a fair city. It was one of the 28 cities built by the Britons before the arrival of the Romans; who made it one of their colonies, and in the eighth century it was esteemed one of the noblest cities in the kingdom. This city sends two members to parliament. It is 34 miles N. N. E. of Bristol.

GLOUCESTER, a fertile and well cultivated county of Virginia.

GLOUCESTER, a town in the above county, 80 miles S. E. of Richmond.

GLOUCESTER ISLAND, OF DUKE OF GLOUCESTER'S ISLAND, an island in the South Sea, six miles long and one broad. The natives are armed with long pikes. Lon. 140. 4. W. Lat. 19. 15. S.

GLOUCESTER ISLANDS, two isles in the South Sea, lying the one in Lon. 146. 0. W. and Lat. 20. 38. S.; the other in Lon. 146. 15. W. and Lat. 20. 34. S.

GLOVES, in commerce, are distinguished into leathern, silk, thread, cotton, worsted, &c. Leathern gloves are made of chamois, kid, lamb, doe, elk, buff, &c. Gloves now pay a duty to the king, which increases according to their value.

GLOW-WORM, in zoology. See LAMPYRIS.

GLOXINIA, in botany, a genus of the didynamia angiospermia class and order; natural order, Personatae. Calyx superior, five-leaved; corolla bell-shaped, with the border oblique; filaments, with the rudiment of a fifth, inserted into the receptacle. There is only one species, viz. *G. maculata*, spotted gloxinia, a native of South America.

GLUCINA, [from *glucina*, to sweeten,] a peculiar earth discovered by Vauquelin in the beryl and emerald, so named from its characteristic property of forming salts of a saccharine taste. Its general properties are these: 1. It is white; 2. insipid; 3. adhesive to the tongue; 4. insoluble in water, and 5. in ammoniac; but, 6. soluble in the fixed alkalis, 7. in the carbonate of ammoniac; and, 8. in almost all the acids, except the carbonic and phosphoric, and forming salts of a saccharine taste; 9. infusible; but, 10. fusible with borax into a transparent glass; 11. it absorbs one-fourth of its carbonic acid; 12. decomposes the aluminous salts; and, 13. is not precipitable by well saturated hydro-sulphurets. Its specific characters, which are not found united in any of the other known earths, are these: 1. Its salts are saccharine, and slightly astringent; 2. It is soluble in the carbonate of ammoniac; 3. It is very soluble in the sulphuric acid by excess; 4. It decomposes the aluminous salts; 5. It is completely precipitated from its solutions by ammoniac; and, 6. Its affinity for

for the acids is intermediate between magnesia and alumina. One hundred parts of beryl contain sixteen of glucina. M. Vauquelin justly remarks, that, "in the sciences, a body, a principle, or a property, formerly unknown, though it may often have been used, or even held in the hands, and referred to other simple species, may, when once discovered, be afterwards found in a great variety of situations, and be applied to many useful purposes. Chemistry affords many recent examples of this truth."

GLUCKSTADT, a considerable town in the duchy of Holstein, 28 miles N. W. of Hamburgh.

GLUE is indifferently denominated according to its preparation and the various uses it is designed for; as common glue, glove-glue, and parchment-glue. But the two last are more properly called size. The common or strong glue is chiefly used by carpenters, joiners, cabinet-makers, &c. It is made of skins of animals, as oxen, cows, calves, sheep, &c. whole skins are rarely used for this purpose, but only the shavings, parings, or scraps of them, or the feet sinews, &c. That made of whole skins, however, is undoubtedly the best; as that made of sinews is the very worst. In making glue of parings, they first steep them two or three days in water; then, washing them well out, they boil them to the consistence of a thick jelly; which they pass, while hot, through ozier-baskets, to separate the impurities; and then let it stand some time to purify it further: when all the filth is settled to the bottom of the vessel, they melt and boil it a second time. They next pour it into flat frames or moulds; whence it is taken out pretty hard and solid, and cut into square pieces or cakes. They afterwards dry it in the wind, in a sort of coarse net; and at last string it to finish its drying. The glue made of sinews, feet, &c. is managed after the same manner; only with this difference, that they bone and scour the feet, and do not lay them to steep. Of this commodity there is a very great exportation from England; the English glue being universally allowed to be the best in Europe, partly from the excellency of the materials, and partly from the skill of the manufacturers. A glue that will hold against fire or water, it is said, may be made thus: Mix a handful of quick-lime with four ounces of linseed-oil; boil them to a good thickness; then spread it on tin-plates in the shade, and it will become exedding hard, but may be easily dissolved over a fire as glue, and will effect the business to admiration.

GLUE, METHOD OF PREPARING AND USING. Set a quart of water on the fire; then put in about half a pound of good glue, and boil them gently together till the glue be entirely dissolved and of a due consistence. When glue is to be used, it must be made thoroughly hot; after which, with a brush dipped in it, besmear the faces of the joints as quick as possible; then clapping them together, rub them lengthwise one upon another, two or three times, to settle them close; and let them stand till they are dry and firm. Mr. Boyle gives the following receipt for preparing a fine strong glue from isinglass: Steep the isinglass for 24 hours in common brandy. When the menstruum has opened and mollified the isinglass, they must be gently boiled together, and kept stirring till they appear well mixed, and till a drop thereof, suffered to cool, turns into a strong jelly. Then strain it, whilst hot, through a clean linen-cloth into a vessel to be kept close stopped. A gentle heat suffices to dissolve this glue into a transparent and almost colourless fluid, but very strong; so that pieces of wood glued together with it will break elsewhere rather than in the place where they are joined.

GLUME. See **BOTANY**.

GLUTA, in botany, a genus of the pentandria monogynia class and order. Calyx bell-shaped, deciduous; petals five, glued at bottom to the column of the germ; filaments inserted into the tip of the column; germ sitting on an oblong column. There is only one species, viz. *G. benghas*, a native of Java.

GLUTEN. If wheat-flour is kneaded into a paste with a little water, it forms a tenacious, elastic, soft, ductile mass. This is to be washed cautiously, by kneading it under a small jet of water till the water no longer carries off any thing, but runs off colourless; what remains behind is called gluten. It was discovered by Beccaria, an Italian philosopher, to whom we are indebted for the first analysis of wheat-flour. 1. Gluten, when thus obtained, is of a grey colour, exceedingly tenacious, ductile, and elastic, and may be extended to twenty times its original length. When very thin, it is of a whitish colour, and has a good deal of resemblance

to animal tendon or membrane. In this state it adheres very tenaciously to other bodies, and has often been used to cement together broken pieces of porcelain. Its smell is peculiar. It has scarcely any taste, and does not lose its tenacity in the mouth. When exposed to the air, it assumes a brown colour, and becomes in a manner covered with a coat of oil. When exposed to the air, it gradually dries; and when completely dry, it is pretty hard, brittle, slightly transparent, of a dark brown colour, and has some resemblance to glue. It breaks like a piece of glass, and the edges of the fracture resemble in smoothness those of broken glass; that is, it breaks with a vitreous fracture. It is insoluble in water, though it imbibes and retains a certain quantity of it with great obstinacy. To this water it owes its elasticity and tenacity. When boiled in water it loses both these properties. Its constituent parts are oxygen, hydrogen, carbon, and azote. It exists most abundantly in wheat, but it is found in large quantities in many other plants. It is gluten that renders wheat so useful in the art of bread-making.

GLYCINE, in botany, a genus of the diadelphia decandria class and order; natural order, Papilionaceæ, or Leguminosæ. Calyx two-lipped; corolla the keel turning back the banner at the tip. There are twenty-five species.

GLYCIRRHIZA, LIQUORICE, a genus of the decandria order, and diadelphia class of plants; natural order, Papilionaceæ. Calyx bilabiate, upper lip tripartite, under one entire; legumen ovate, compressed. There are four species.

G. GLABRA, the COMMON LIQUORICE; has long, thick, creeping roots, striking several feet deep into the ground; upright, firm, annual, herbaceous stalks, three or four feet high, garnished with winged leaves of four or five pair of oval lobes, terminated by an odd one; and from the axillas erect spikes of pale blue flowers in July, succeeded by short smooth pods. The root is the useful part, which is replete with a sweet, balsamic, pectoral juice, much used in compositions for coughs and disorders of the stomach. These plants are very hardy perennials; but this last is the sort commonly cultivated for use, its roots being fuller of juice and sweeter than the others. The roots are perennial; but the stalks rise in spring, and decay in autumn. They are propagated by cuttings of the small roots issuing from the sides of the main ones near the earth, divided into lengths of six or eight inches, each having one or more good buds. The proper season for procuring the sets for planting is in open weather from October to March; but from the middle of February till the middle of March is rather the best season for planting. An open situation is to be preferred. The soil ought to be of a light loose temperature, and three or four feet deep: for the roots of liquorice will arrive at that depth and more, and the longer the roots the more valuable they are. The ground should be trenched three spades deep; then proceed to plant the sets, by line and dibble, a foot distant in each row; putting them perpendicular into the ground, with the tops about an inch under the surface; let the rows be a foot or a foot and a half asunder.

GMELIN, SAMUEL GOTTLIEB, LL. D. professor at Tubingen, and member of the Imperial Academy of Sciences at St. Petersburg, was born at Tubingen in 1745. He was celebrated for his knowledge in natural history, as well as for his travels, which he commenced in June 1768. Having traversed the provinces of Moscow, Veronetz, New Russia, Azot, Casan, and Astracan, he visited, in 1770 and 1771, the harbours of the Caspian, and examined with attention those parts of the Persian provinces which border on that sea, of which he has given a circumstantial account in the three first volumes of his Travels. Anxious to extend his observations, he attempted to pass through the western provinces of Persia, which are infested by numerous banditti; and quitted, in April 1772, Einzille, a small trading-place in Ghilan, upon the southern shore of the Caspian; and, on account of many difficulties and dangers, did not, until Dec. 2, 1773, reach Sallian, a town upon the mouth of the Koor. Thence he proceeded to Baku and Kuba, in Shirvan, where he met with a friendly reception from Ali Feth Khan, the sovereign of that district. After he had been joined by twenty Uralian Cossacks, and when he was only four days journey from the Russian fortress Kislar, he and his companions were, on the 5th of Feb. 1774, arrested by the order of the Usmei Khan, a petty Tartar prince, through whose territories he was obliged to pass. Usmei urged as a pretence for this arrest, that

that thirty years ago several families had escaped from his dominions, and had found an asylum in the Russian territories; adding, that Gmelin should not be released until these families were restored. The professor was removed from prison to prison; and at length, wearied out with continued persecutions, he expired, July 27th, at Achmet-Kent, a village of Mount Caucasus. His death was occasioned partly by vexation for the loss of several papers and collections, and partly by disorders contracted from the fatigues of his long journey. Some of his papers had been sent to Kislar during his imprisonment, and the others were, with great difficulty, rescued from the hands of the barbarian who had detained him. The arrangement of these papers, which now form the fourth volume of his Travels, was at first consigned to the care of Guildenstaedt, but upon his death was completed by Dr. Pallas.

GMELENA, in botany, a genus of the angiospermia order, and didynamia class of plants; natural order, Personate. Calyx slightly four-toothed; corolla four-cleft, bell-shaped; anthers two-parted, two simple; drupe with a two or three-celled nut. There is but one species, viz. *G. asiatica*.

GNAPHALIUM, **CUDWEED**, **GOLDYLOCKS**, **ETERNAL** or **EVERLASTING FLOWER**, &c. a genus of the polygamia superflua order, and syngenesia class of plants; natural order, Compositæ. Calyx imbricate, with the marginal scales rounded, scariose, coloured; down feathered; receptacle naked. There are sixty-six species. The numerous species of this genus are chiefly under shrubs or herbs; the leaves are alternately placed, generally hoary; the flowers usually terminate the stem and branches in globes or corymbs. The calyx is permanent with yellow or white scales.

GNAT, in zoology. See **CULEX**.

GNAT-FLOWER. See **OPHRYS**.

GNIESS, in mineralogy, is composed principally of felspar, quartz, and mica, forming plates, laid on each other, and separated by thin layers of mica. It differs from granite by being shistose; though, like that, it sometimes contains shorl and garnet. The beds of gneiss sometimes alternate with layers of granular limestone, shistose, hornblende, and porphyry. It is rich in ores, almost every metal has been found in gneiss-rocks, either in veins or beds. Mr. Jameson mentions four kinds of gneiss: 1. That which approaches to the granular structure. 2. The waved or undulated. 3. The common; and, 4. The thin slaty.

GNESEN, **GNESNA**, **GNESNO**, or **GNIESNO**, a town of Great Poland, of which it is the capital, in the palatinate of Kalish, 100 miles N. E. of Breslaw.

GNETUM, in botany, a genus of the monadelphia order, and monœcia class of plants. Male ament with scales; no corolla, and but one filament with a pair of antheræ; fruit a monospermous plum.

GNIDIA, in botany, a genus of the monogynia order, and octandria class of plants. Calyx funnel-shaped, quadrifid, with four petals inserted into it; one seed, somewhat resembling a berry. It has eleven species.

GNIEW, or **MEVA**, a town of the Duchy of Warsaw, in Pomerelia, on the Vistula; 22 miles S. of Dantzic.

GNOMES, or **GNOMI**, imaginary beings, who, according to the cabalists, inhabit the inner parts of the earth. They are supposed to be small in stature, and guardians of quarries, mines, &c.

GNOMON. See **DIAL** and **DIALING**. The word γνομων literally implies something that makes a thing known; as the style of a dial makes the hour known.

GNOMON, in geometry. If in a parallelogram ABCD, (Plate LXXV. fig. 8,) the diameter AC be drawn; also two lines EF, HI, parallel to the sides of the parallelogram, and cutting the diameter in one and the same point G, so that the parallelogram is, by these parallels, divided into four parallelograms, then are the two parallelograms DG, BG; through which the diameter does not pass, called complements; those through which the diameter passes, EH, FI, are called the parallelograms about the diameter; and a gnomon consists of the two complements, and either of the parallelograms about the diameter, viz. GD + HE + EI, or GD + FI + GB.

GNOMON, in astronomy, a style erected perpendicular to the horizon, to find the altitude of the sun. Thus, in the right-an-

gled triangle ABC, (Plate LXXV. fig. 10,) are given, AB the length of the style, BC the length of its shadow, and the right angle ABC. Hence, making BC the radius, we have this analogy for finding the angle ACB, the sun's altitude, viz. BC : AB :: radius : tangent of the angle C. By a gnomon, the sun's meridian-altitude, and consequently the latitude of the place, may be found more exactly than with the smaller quadrants. See **QUADRANT**. By this instrument the height of any object GH may be found: for as DE, the distance of the observer's eye from the gnomon, is to DE, the height of the style; so is FH, the distance of the observer's eye from the object, to GH, its height.

GNOMONICS, [γνομωνικη], a science which teaches to find the just proportion of shadows for the construction of all kinds of dials, and for knowing what o'clock it is by means thereof: as also of a gnomon or stile, that throws off the shadow for this purpose. See **DIALING**.

GNOSSOS, or **GNOSSUS**, in ancient geography, a city of Crete. See **CRETE**.

GNOSTICS, [from γνωστικός, knowing,] ancient heretics, famous from the first rise of Christianity, principally in the east. It appears from several passages of Scripture, particularly 1 John ii 18, 1 Tim. vi. 20; and Col. ii. 8, that many persons were infected with the Gnostic heresy in the first century; though the sect did not render itself conspicuous, either for numbers or reputation, before the reign of Adrian, when some writers erroneously date its rise. The name was adopted by this sect, on the presumption that they were the only persons who had the true knowledge of Christianity. Accordingly, they looked on all other Christians as simple, ignorant, and barbarous persons, who explained and interpreted the sacred writings in a low, literal, and unedifying signification. At first the Gnostics were the only philosophers and wits of those times, who formed for themselves a peculiar system of theology, agreeable to the philosophy of Pythagoras and Plato; to which they accommodated all their interpretations of scripture. But

GNOSTICS afterwards became a generical name, comprehending divers sects and parties of heretics, who rose in the first centuries, and who, though they differed among themselves as to circumstances, yet all agreed in some common principles. They corrupted the doctrine of the gospel by a profane mixture of the tenets of the oriental philosophy, concerning the origin of evil and the creation of the world, with its divine truths. Such were the Valentinians, Simonians, Carpocratians, Nicolaitans, &c.

GOA, an island of the Indian Ocean near the west and Malabar coast of Hindostan, separated from the continent by the Mandova. It is twenty-two miles long and six broad. The soil is fertile, and produces excellent fruits, corn, &c. The climate is moderate from October to March; in April and May very sultry, and from June to September almost constant rain.

GOA, a strong city of Asia, the capital of the above island. The chief trade of Goa, is in Arrack. Lon. 73° 58' 39" E. Lat. 15° 28' 20" N.

GOA, a town in the island of Celebes, near the south coast.

GOAR, **ST. ST. GEVER**, or **ST. GOWER**, a town of Germany, now in the department of the Rhine and Moselle, lately in the territory of Hesse Rheinfeldt. It lies 15 miles S.E. of Coblenz.

GOAT, in zoology. See **CAPRA**.

GOAT'S-BEARD. See **TRAGOPOGON**.

GOAVE, **LITTLE**, or **GOAVE**, **PETIT**, a sea-port of Hispaniola, 20 miles W.S.W. of Leogane.

GOBIN, **ST.** a town and castle of France, in the department of Aisne, and late province of Picardy, near Fere.

GOBIUS, in ichthyology, a genus of fishes of the order thoracici. They have two holes between the eyes, four rays in the membrane of the gills, and the belly fins are united in an oval form. There are twenty species, principally distinguished by the number of rays in their fins.

G. NIGER, or the **BLACK GOBY**, is about six inches in length, a native of the Mediterranean and North Seas. It is eaten, but not highly valued.

G. LANCEOLATUS, **LANCE-TAILED GOBY**, is a native of the West Indies, and peculiar in the form of its tail. See Plate LV.

GOBLETS, are ordinarily of a round figure, and without either foot or handle. Budeus deduces the word from the Greek κωπελλον, a sort of cup.

GOCH,

GOCH, a town of France, in the department of the Roer, and late duchy of Cleves, 6 miles S. of Cleves.

GOD, the Supreme Being, the first cause or creator of the universe, and the only true object of religious worship. The Hebrews called him Jehovah; which name they never pronounced, but used instead of it the words Adonai, or Elohim. He is incomprehensible in his nature, and can only be known so far as he reveals himself. The existence and preservation of all beings depend on him, and because of his infinity he can superintend and take care of the whole, and of each individual of created beings, as though there were but one. He has wonderfully displayed his goodness and care over his creatures, as also his wisdom, justice, and truth, in his proceedings towards man, and in the method he took to restore him to that happiness which he had forfeited. See **CHRISTIANITY**, **METAPHYSICS**, **MORAL PHILOSOPHY**, and **THEOLOGY**.

GOD, is also used in speaking of the false deities of the heathens, who were only creatures and imaginary beings to which divine honours and worship were superstitiously paid. The Greeks and Latins did not mean by the name of God an all-perfect being, whereof eternity, infinity, omnipresence, &c. were essential attributes: with them the word only implied an excellent and superior nature; and accordingly they gave the appellation gods to all beings of a rank or class higher and more perfect than that of men, and especially to those who were inferior agents in the divine administration, all subject to the one Supreme. Thus men themselves, according to their system, might become gods after death; inasmuch as their souls might attain to a degree of excellence superior to what they were capable of in life. See **MYTHOLOGY**.

GODAVERY, **GODURY**, or **GONDA**, a river of Hindostan, which rises about 70 miles N.E. of Bombay, and whose waters, at least in the upper part of its course, are esteemed sacred by the Hindoos. Its waters fall into the bay of Bengal by various mouths.

GODDARD, **JONATHAN**, M.D. an eminent physician and chemist, and one of the first promoters of the Royal Society. He was born about 1617; educated and graduated at Oxford; was elected a fellow of the college of physicians in 1646, and appointed reader of the anatomical lecture in 1647. Oliver Cromwell appointed him first physician to the army, a member of the council of state, and warden of Merton college. But he lost his office on the restoration. He was elected professor of physic in Gresham college, in 1655. He prepared all his own medicines; and in published 1668, a treatise recommending that practice to all physicians. He was the inventor of the Gutta Anglicana. He died of an apoplectic fit in 1674. Bishop Seth Ward says, he was the first Englishman who made a telescope.

GODDESSES. The ancients had almost as many goddesses as gods: such were Juno, Minerva, Diana, &c. The virtues, graces, and principal advantages of life; truth, justice, piety, liberty, fortune, victory, &c. were all represented as goddesses; which was paying no small compliment to the fair sex. But to balance this the furies, harpies, &c. were also represented as goddesses.

GODEAU, **ANTHONY**, bishop of Grasse and Vence, in France, was born at Dreux in 1605. He was a very voluminous writer. His principal works are 1. An Ecclesiastical History, in three volumes folio, containing the first eight centuries, as he never finished more. 2. Translation of the Psalms into French Verse, which was so well approved, that even those of the reformed religion preferred it to that of Marot. He died in 1671.

GODFATHERS and **GODMOTHERS**, are persons who at the baptism of infants answer for their future conduct, and solemnly promise that they will renounce the devil and all his works, and follow a life of piety and virtue; and thus lay themselves under an indispensable obligation to instruct them, and watch over their conduct. This custom is of great antiquity in the Christian church, and was probably introduced to prevent children being brought up in idolatry, in case their parents died before they arrived at the years of discretion. The number of godfathers and godmothers was formerly great, but is reduced to two in the church of Rome, and three in the church of England.

GODMAN, an epithet applied to our Saviour, from the divine and human natures being united in his person.

GODMOTHERS. See **GODFATHER**.

GORDA, a circar of Hindostan, in Guzerat.

GORDA, the capital of the above circar, 55 miles E. of Amedabad. Lon. 73. 40. E. Lat. 22. 50. N.

GOES, or **TER-GOES**, a town of Zealand, 10 miles E. of Flushing.

GOEZ, **DAMIAN DE**, a Portuguese author of great repute, born at Alangar, of a noble family, and educated at the court of king Emanuel. He travelled through the chief countries of Europe, and became acquainted with Erasmus, Jo. and Olaus Magnus, cardinals Rembus and Madrucius, Conrad Gloenius, Peter Nannius, and other literati. He married, and spent several years at Louvain; and not only wrote the history of its siege in 1542, but bravely put himself at the head of the soldiers, and contributed much to its defence. After this king John III. recalled him into Portugal, in order to write the history of that kingdom; but the favours with which that monarch loaded him, procured him so much envy, that he was first falsely accused and confined to Lisbon, and afterwards found murdered in his own house. He wrote, 1. Fides, Religio, Moresque Æthiopum. 2. De Imperio et Rebus Lusitanorum. 3. Hispania. 4. Urbis Olissiponensis Descriptio. 5. Chronica do Rey Dom Emanuel. 6. Historia do Principe Dom Joan; and other works which have been often printed, and are esteemed.

GOG and **MAGOG**, two names generally joined together in scripture, Ezek. xxxviii. 2, 3, &c. xxxix. 1, 2, &c. Rev. xx. 8. Moses speaks of Magog the son of Japhet, but says nothing of Gog, Gen. x. 2, 1 Chr. i. 5. Gog was the prince of Magog, according to Ezekiel, Magog being the name of the country or people. The generality of the ancients made Magog the father of the Scythians and Tartars; and several interpreters discovered many footsteps of their name in the provinces of Great Tartary. Others supposed that the Persians were the descendants of Magog. Some have imagined that the Goths were descended from Gog and Magog; and that the wars described by Ezekiel, and undertaken by Gog against the saints, are those which the Goths carried on against the Roman empire, in the fifth century. Bochart has placed Gog in the neighbourhood of Caucasus. He derives the name of this celebrated mountain from the Hebrew *Gogchasan*, "the fortress of Gog." He maintains that Prometheus, said to be chained to Caucasus by Jupiter, is Gog, and no other. There is a province in Iberia, called Gogarene. Most Commentators think that Gog and Magog, mentioned in Ezekiel and the Revelation, are to be taken in an allegorical sense, for such princes as were enemies to the church and saints. Others think that Gog and Magog in the Revelation denote all the enemies of the church, who should be persecutors of it to the consummation of ages. But the most probable opinion appears to be, that the Gog and Magog in Ezekiel, is the future grand confederation of all the apostate Gentile nations against the re-establishment of the Jews in their own land; and that the Gog and Magog in the Revelation is the apostasy that will take place at the close of the Millennium, a little before the consummation of all things.

GOGGLES, in surgery, instruments used for curing squinting, or that distortion of the eyes which occasions this disorder. They are short conical tubes, composed of ivory stained black, with a thin plate of the same ivory fixed in the tubes near their anterior extremities. Through the centre of each of these plates is a small circular hole, about the size of the pupil of the eye, for the transmission of the rays of light. These goggles must be continually worn in the day-time, till the muscles of the eye are brought to act regularly and uniformly, so as to direct the pupil straight forwards; and by these means the cure will be sooner or later effected.

GOGLAND, an island of Russia, in the Gulf of Finland, 80 miles W. of Petersburg.

GOGO, a town of Hindostan, 64 miles N.W. of Surat.

GOGRA, or **SOORJEW**, a large river of Asia, which rises in Thibet, and joins the Ganges above Chuprah in Bahar.

GOHUD, a circar of Hindostan, in Agra.

GOGUD, the capital of the above circar, 55 miles S.S.E. of Agra.

GOJAM, a province of Abyssinia, remarkable for having in it the sources of the Nile. It is about 75 miles long from north to south, and 42 broad from east to west.

GOITO, a town of the late Cisalpine republic, in the department of Mincio, and the late duchy of Mantua, 9 miles N. N. W. of Mantua.

GOLCONDA,

GOLCONDA, a province of Hindostan, in the Deccan, bounded on the north by Berar, on the east by the gulf of Bengal, on the south by Mysore and the Carnatic, and on the west by Dowlatabad and Visiapour. It was anciently called Tellingana, or Tilling, and was an independent kingdom. Hyderabad is the capital.

GOLCONDA, a fortress and town of the above kingdom, which form one of the largest cities in the East-Indies, 5 miles W.N.W. of Hyderabad. Lon. 70. 10. E. Lat. 16. 30. N.

GOLD, [gold, Sax. *golud*, riches, Welsh. It is called gold in our English tongue, either of *geel*, as Scaliger says, which is in Dutch to shine; or of another Dutch word, which is *gellen*, and signifies in Latin *valere*, in English to be of price or value: hence cometh their ordinary word *gelt*, for money. *Peacham on Drawing.*] Gold is one of the heaviest, most dense, most simple, most ductile, and most fixed of all bodies, not to be injured either by air or fire, and seemingly incorruptible. It is soluble by means of sea-salt; but is injured by no other salt. Gold is frequently found native, and very rarely in a state of ore. Pure gold is so fixed, that Boerhaave informs us of an ounce of it set in the eye of a glass-furnace for two months, without losing a single grain. Gold hath these natures, greatness of weight, closeness of parts, fixation, plianthness, immunity from rust, and the colour or tincture of yellow. It is the most valuable of all the metals, is of a bright yellow colour, when pure; but becomes more or less white or high-coloured, in proportion as it is alloyed with silver or copper. It is the heaviest of all known bodies, platina only excepted, its specific gravity being to that of distilled water at 19.640 to 1000. It melts in a low white heat; requiring, according to Mr. Wedgwood's calculation, 5237 degrees of Fahrenheit's, or 32 of his own, thermometer for its fusion; a heat greatly superior to that which melts silver or copper; the former requiring only 4717, and the latter 4587 of Fahrenheit. Other metallurgists, however, assert that copper requires for its fusion a greater degree of heat than either gold or silver; and this is confirmed by the experience of those who work in these metals. The method of extending gold used by the gold-beaters, consists in hammering a number of thin-rolled plates between skins or animal membranes. It is the most ductile, as well as the most malleable, of all metals. According to Cronstedt, one grain of it may be stretched out so as to cover 98 Swedish ells, equal to 63.66 English yards of silver-wire; but Wallerius asserts, that a grain of gold may be stretched in such a manner as to cover 500 ells of wire. At any rate, the extension is prodigious; for according to the least of these calculations, the millionth part of a grain of gold may be made visible to the naked eye. Nor is its malleability inferior to its ductility. Boyle, quoted by Apligny in his Treatise of Colours, says, that one grain and an half of gold may be beaten into 50 leaves of one inch square, which, if intersected by parallel lines drawn at right angles to each other, and distant only the 100th part of an inch from each other, will produce 25 millions of little squares, each very easily discernible by the naked eye. The limits of the ductility and malleability of gold are not known, and its tenacity exceeds that of any other metal. A gold wire of one-tenth of an inch diameter, requires 500lb. weight to break it. Gold-leaf exhibits a fine green colour on being interposed between the eye and the beams of the sun or any other luminous body. When exposed for some time to a strong heat, it becomes ignited, and at last melts, assuming a fine, bluish, green, colour; and, when cold, crystallizes into quadrilateral pyramids. Gold is more generally found native than any other metal; though Bergman says, he does not know an instance of its ever being found perfectly free of alloy. Kirwan says it is seldom found so, being generally alloyed with silver, copper, or iron, and sometimes with all the three. According to Wallerius, native gold is found, 1. In solid masses, in Hungary, Transylvania, and Peru. 2. In grains, in the Spanish West Indies. 3. In a vegetable form, like the branches or twigs of plants. 4. In a drusic figure, as if composed of groups or clusters of small particles united together, found in Hungary. 5. Composed of thin plates, on thin pellicles, covering other bodies, found in Siberia. 6. In a crystalline form in Hungary. Gold is also found in the form of thick solid pieces. It is, in general, more frequently imbedded in quartz, and mixed with it, than with any other stone; and the quartz in which the gold is found in the Hungarian mines, Mr. Magellan tells us, is of a peculiarly mild ap-

pearance. Sometimes, however, it is found in limestone, hornblende, &c. Europe is principally supplied with gold from Chili and Peru in South America. A small quantity is likewise imported from China and the coast of Africa. The principal gold-mines of Europe are those of Hungary, Saltzburg, and Adelfors, in Smaland. Some gold is also extracted from the silver mines of Ostervarberget, in the province of Dalarna. Native gold has been found in Lapland, above Tornea, and in Westmanland. In Peru it is found mixed with a stony matter not well known; from which it is extracted by amalgamation. Gold is also found separate from any matrix, in lumps of visible grains mixed with sands, in the beds of rivers. It is visibly dispersed through masses of sand, of a yellowish-red, or violet colour. In this state it is so universally diffused through every kind of earth, that Mr. Bergman thinks it the most common of all the metals, iron excepted. If 100lb. of sand contain 24 grains of gold, the separation is said to be worth attending to. In Africa 5lb. of sand often yield 63 grains of gold, or even more; and the heaviest sand, which is often black or red, contains the most. The strongest heat of any furnace does not change the metallic properties of gold. Messrs. Boyle and Kunckel kept gold for several months in the fire of a glasshouse without producing any change upon it. It appears, however, that, by the violent heat of the sun-beams, collected in the focus of a burning-glass, some alteration may be produced in it. Homberg observed that gold, when exposed to the lens of Tschirnhausen, formed, was volatilized, and even vitrified; and Macquer found, that the metal, when exposed to the lens of Mr. Trudaine, exhaled a fume which gilded silver, and was therefore gold in a volatile state. No acid acts readily upon gold but the nitro-muriatic acid, called aqua-regia, and the oxygenized muriatic acid. When gold is immersed in aqua-regia, an effervescence takes place with the escape of gas; the solution tinges animal matters of a deep purple, and corrodes them. By careful evaporation, fine crystals of a topaz-colour are obtained. The gold is precipitated from its solvent by a great number of substances. Lime and magnesia precipitate it in the form of a yellowish powder. Alkalies exhibit the same appearance; but an excess of alkali re-dissolves the precipitate. Ammonia precipitates the solution of gold much more readily than fixed alkalies. This precipitate, which is of a brown, yellow, or orange colour, possesses the property of detonating with a very considerable noise, when gently heated. It is known by the name of fulminating gold. The presence of ammonia is necessary to give the fulminating property to the precipitate of gold; and it will be produced by precipitating it with fixed alkali from an aqua-regia previously made by adding sal-ammoniac to nitric acid; or by precipitating the gold from pure aqua-regia, by means of sal-ammoniac, instead of the ammonia alone. The fulminating gold weighs one-fourth more than the gold made use of. A considerable degree of precaution is necessary in preparing this substance. It ought not to be dried but in the open air, at a distance from a fire, because a very gentle heat may cause it to explode. Several fatal accidents have arisen from its explosion, in consequence of the friction of ground-stoppers in bottles containing this substance, of which a small portion remained in the neck. Fulminating gold, according to the results of Berthollet's experiments, consists of oxide of gold combined with ammonia. Sulphurets, and most metals, precipitate gold from aqua-regia. Most metals unite with gold by fusion. With silver it forms a compound, which is paler in proportion to the quantity of silver added. It is remarkable that a certain proportion, for example, a fifth part, renders it greenish. From this circumstance, as well as from that of a considerable proportion of these metals separating from each other by fusion, in consequence of their different specific gravities, when their proportions do not greatly differ, it should seem that their union is little more than a mere mixture without combination; for, as gold-leaf transmits the green rays of light, it will easily follow that particles of silver, enveloped in particles of gold, will reflect a green, instead of a white, light. A strong heat is necessary to combine platina with gold: it greatly alters the colour of the gold if its weight exceed the forty-seventh part of the mass. Mr. Francillon, however, informs us, that six parts of gold and one of malleable platina produce a metal of a beautiful colour, great malleability, susceptible of a fine polish, and more unalterable than gold itself. It does not much affect the ductility. Mercury is strongly disposed to unite with gold, in all proportions

proportions with which it forms an amalgam: this, like other amalgams, is softer, the larger the proportion of mercury. It softens and liquefies by heat, and crystallizes by cooling. Lead unites with gold, and considerably impairs its ductility, one-fourth of a grain to an ounce rendering it completely brittle. Copper renders gold less ductile, harder, more fusible, and of a deeper colour. This is the usual addition in coin, and other articles used in society. Tin renders it brittle in proportion to its quantity. Bismuth renders gold white and brittle; as do likewise nickel, manganese, arsenic, and antimony. Zinc produces the same effect; and, when equal in weight to the gold, a metal of a fine grain is produced, which is said to be well adapted to form the mirrors of reflecting telescopes; being susceptible of a very fine polish, and not subject to rust.

GOLD, PURE, that purged by fire of all its impurities, and all alloy. The moderns frequently call it gold of twenty-four carats, but in reality there is no such thing as gold so very pure, and there is always wanting at least a quarter of a carat. Gold of twenty-two carats has one part of silver and another of copper; that of twenty-three carats has half a part, *i. e.* half a twenty-fourth of each. See **CARAT**.

GOLD, MOSAIC, is gold applied in pannels on a proper ground, distributed into squares, lozenges, and other compartments; part of which is shadowed to raise or heighten the rest. See **MOSAIC**.

GOLD PLATES FOR ENAMELLING are generally made of ducats whose fineness is from $23\frac{1}{2}$ carats to $23\frac{3}{4}$; as the finest gold is the best for this purpose, unless where some parts of the gold are left bare and unpolished, as in watch-cases, snuff-boxes, &c. for which purposes a mixture of alloy is necessary, and silver is preferred to copper, because the latter disposes the plates to tarnish and turn green. See **ENAMEL**.

GOLD, SHELL, is that used by the gilders and illuminers, and with which gold-letters are written. It is made by grinding gold-leaves, or gold-beaters fragments, with a little honey, and afterwards separating the honey from the powdered gold by water. When the honey is washed away, the gold may be put on paper or kept in shells; whence its name. When it is used, it is diluted with gum-water or soap-suds. The German gold-powder, prepared from the Dutch gold-leaf in the same manner, is generally used; and when it is well scoured with varnish, answers the end in japanner's gilding as well as the genuine.

GOLD, SPUN, or GOLD THREAD, is flattened gold-wire wrapped over a thread of silk, by twisting it with a wheel and iron bobbins.

GOLD-WIRE, a cylindrical ingot of silver, gilt, or covered with gold, and afterwards drawn successively through a great number of little round holes, of a drawing iron, each less than the other, till it be sometimes no bigger than a hair. See **WIRE-DRAWING**.

GOLD-WIRE, PLATTED, is the above wire flattened between two rollers of polished steel, to fit it to be spun on a stick, or to be used flat without spinning, as in brocades, laces, embroideries, &c.

GOLD COAST, in geography, a maritime country of Africa, on the coast of Guinea, abounding with gold; and extending 180 miles in length from Gold River to Ponné.

GOLD RIVER, a river of Africa, in Guinea, the sands of which abound with gold-dust.

GOLD RIVER, a river of America, on the Isthmus of Darien, abounding also with gold-dust.

GOLDAPP, a town of Prussian Lithuania, founded in 1564; sixty-eight miles E. S. E. of Königsberg.

GOLDBERG, a town of Silesia, in the duchy of Lignitz, eleven miles W. N. W. of Jauer.

GOLDEN CUPS. See **RANUNCULUS**.

GOLDEN EAGLE. See **FALCO**.

GOLDEN FISH. See **CYPRINUS**.

GOLDEN FLEECE, in the ancient mythology, was the skin and fleece of the ram upon which Phryxus and Helle are said to have swam over the sea to Colchis; and which being sacrificed to Jupiter, was hung upon a tree in the grove of Mars. See **ARGO-NAUTS**.

GOLDEN FLEECE, ORDER OF THE, a military order instituted by Philip the Good, duke of Burgundy, in 1427; thus named from a representation of the golden fleece, borne by the knights on their collars, which consisted of flints and steels.

GOLDEN ISLAND, an island of S. America, in the Gulf of Darien, and province of Terra Firma. Lon. 77. 10. W. Lat. 9. 0. N.

GOLDEN NUMBER, in chronology, a number shewing what year of the moon's cycle any given year is. See **CHRONOLOGY**.

GOLDEN RULE. See **ARITHMETIC**.

GOLDEN THISTLE. See **SCOLYMUS**.

GOLDFINCH, in ornithology. See **FRINGILLA**.

GOLDINGEN, a town of Poland, in the duchy of Courland, forty-eight miles W. N. W. of Mittau.

GOLD-SIZE, FOR BURNISHED GILDING, is prepared of $1\frac{1}{2}$ lb. of tobacco-pipe clay, $\frac{1}{2}$ oz. of red chalk, $\frac{1}{2}$ oz. of black lead, 40 drops of sweet oil, and 3 drachms of pure tallow: grind the clay, chalk, and black lead, separately, very fine in water, then mix them together, add the oil and tallow, and grind the mixture to a due consistence.

GOLD-SIZE, FOR JAPANING, may be made by pulverising gum animi and asphaltum, of each 1 oz. red lead, litharge of gold, and umbre, of each $1\frac{1}{2}$ oz. mixing them with 1 lb. of linseed-oil, and boiling them; stir them till the whole be incorporated, and appears when cold of the consistence of tar: strain the mixture through a flannel, and keep it stopped up in a bottle for use. When used, it must be ground with as much vermilion as will give it an opaque body, and diluted with oil of turpentine, so that it may be worked freely with the pencil. A more simple preparation is made with 1 lb. of linseed-oil, and 4 oz. of gum animi; powder the gum, and mix it gradually with the boiling oil; let it continue to boil till it becomes of the consistence of tar; strain it through a coarse cloth; keep and use it as the other.

GOLDSMITH, OLIVER, an eminent writer, was born, according to one account, in 1731, at Pallas, in the county of Longford, in Ireland, and to another at Elphin, in 1729. His father was a clergyman, who gave him a good education, and sent him to Trinity College, Dublin, from whence he removed to Edinburgh, to study physic. At this place he became security for a fellow-student, on which account he was obliged to escape to England, but was arrested at Sunderland, and released by two college-friends, whom he met with there. He then went to Holland, and travelled through Flanders, and part of Germany, on foot. At Louvain he took the degree of Bachelor of Physic, the highest degree he ever attained. After accompanying an English gentleman to Geneva, and the south of France, he arrived in England in 1758. Being reduced to a low state, he became usher in a school at Peckham; where, however, he did not remain long, but settled in London, and subsisted by writing for periodical publications. He first emerged from obscurity in 1765 by the publication of his poem, entitled, *the Traveller, or a Prospect of Society*. The year following appeared his beautiful novel of the *Vicar of Wakefield*. He now took chambers in the Temple; but the liberality of his temper, and a propensity to gaming, involved him in frequent difficulties. In 1768 he brought out his comedy of the *Good-Natured Man* at Covent Garden. In 1770 he published *The Deserted Village*, a poem, which, in point of description and pathos, is above all praise. As a comic poet he appeared to great advantage in 1772, by the play of *She Stoops to Conquer*, or *the Mistakes of a Night*. He died by taking an extravagant dose of James's powder in 1774, and was buried in the Temple church-yard. A monument was erected to his memory in Westminster-abbey, with a beautiful Latin epitaph by Dr. Johnson. Besides the above works, he produced a number of others: as a *History of England*, in a Series of Letters from a Nobleman to his Son, 2 vols. 12mo. A *History of England*, 4 vols. 8vo.; A *Roman History*, 2 vols. 8vo.; A *Grecian History*, 2 vols.; A *History of the Earth and Animated Nature*, 8 vols. 8vo.; *Chinese Letters*, &c. A *View of Experimental Philosophy*, 3 vols. 8vo.; A *Posthumous Work*, *Miscellanies*, &c.

GOLDSMITH, or SILVERSMITH, is an artist who makes vessels, utensils, and ornaments, in gold and silver. As the goldsmith often has to make his own moulds, he ought to be a good designer, and have a taste in sculpture: he also ought to know enough of metallurgy to be able to assay and refine gold and silver, and to mix the exact quantity of alloy. The goldsmiths in London employ different hands under them for the various branches of their trade; such as jewellers, box-makers, toy-makers, turners, gilders, burnishers, chasers, refiners, founders, &c. Goldsmiths are superior tradesmen: their wares must be assayed by the wardens of their own company in London, and marked; and the gold and silver must be of the standard fineness, under a penalty of 10*l.* Any false metal may be seized and forfeited to the king.

The cities of Edinburgh, York, Exeter, Bristol, &c. have also places appointed for assaying gold and silver plate. Plate sent to the assay-office, when discovered to be coarser than the standard, is broken and defaced; and the fees for assaying are limited.

GOLIUS, JAMES, a celebrated professor of Arabic and the mathematics at Leyden, descended from a very honourable family, and born at the Hague in 1596. He studied at Leyden, under Erpinus; and, having acquired all the learned languages, travelled into Asia and Africa. He was esteemed and honoured by Muley Zidan, emperor of Morocco and the Grand Signior. He brought home many MSS. to Leyden; and in 1624, succeeded Erpinus. As he had been an eye-witness of the wretched state of Christianity in the Mohammedan countries, none ever solicited for a place of honour and profit with greater eagerness, than he did to procure a new edition of the New Testament, in the original language, with a translation into the vulgar Greek, by an Archimandrite; and as some of these Christians use the Arabic tongue in divine service, he also dispersed among them an Arabic translation of the Confession of the Protestants, with the Catechism and Liturgy. He was likewise appointed interpreter to the states for the Arabic, Turkish, Persian, and other eastern languages. He published, 1. The Life of Tamerlane, in Arabic. 2. The History of the Saracens, written by Elmacin. 3. Alferganus's Elements of Astronomy, with a new Version, and Learned Commentaries. 4. An Excellent Arabic Lexicon. 5. A Persian Dictionary. He died in 1667.

GOLNOW, or **GOLNAW**, a town of Upper Saxony, in Pomerania, twelve miles N. of Stargard.

GOMBRON, or **GOMBROON**, a city of Persia, in the province of Farsistan, called by the natives Bander. Lon. 36. 35. E. Lat. 27. 30. N.

GOMERA, or **GOMARA**, one of the Canary islands, between Ferro and Teneriffe.

GOMERA, a town in the above island, with an excellent harbour. Lon. 17. 8. W. Lat. 28. 6. N.

GOMORRAH, in ancient geography, one of the cities of the plain, or vale of Siddim in Judea, destroyed together with Sodom, by fire from heaven, on account of the wickedness of the people. To determine its particular situation is now impossible.

GOMPHOSIS, [*γομφωσις*], in anatomy, a species of articulation, wherein one bone is set in the other, like a nail or peg; as the teeth within the jaws.

GOMPHIA, in botany, a genus of the decandria monogynia class and order. Calyx five-leaved; corolla five-petaled; berries two, on a large receptacle; seed solitary. There are three species.

GOMPHRENA, **GLOBE AMARANTH**; in botany, a genus of the pentandria digynia class and order. Calyx coloured, outer three-leaved; leaflets two, converging, keeled; petals rude, villose; nectary cylindric, five-toothed; style cloven half-way; capsule seed. There are nine species.

GONATOCARPUS, in botany, a genus of the tetrandria monogynia class and order. Corolla four-cleft; drupe eight-cornered, one-seeded. It has only one species, viz. *G. micranthus*.

GONAVE, an island on the W. coast of Hispaniola, thirty miles long, and five broad. The longitude of its N. E. point is $72^{\circ} 56' 27''$ W. from Greenwich, and its latitude $18^{\circ} 48' 35''$ N.

GONDAR, the capital of Abyssinia, seated on the top of a hill of considerable height. Lon. 37. 33. E. Lat. $12^{\circ} 34' 30''$ N.

GONDOLA, a flat boat, very long and narrow, chiefly used at Venice to row on the canals. The word is Italian. Du Cange derives it from the vulgar Greek *κοννικας*, a bark, or little ship.

GONDREVILLE, a town of France, in the department of Meurthe, three miles N. E. of Toul.

GONG, in music, an instrument used in China, is made of a metal composed of silver, lead, and copper, and its shape is a sort of circular concave. The tone is loud, harsh, and clanging. It is never introduced except on occasion of giving a national cast to the music in which it is employed, or to awaken surprize, and rouse the attention of the company.

GONGA, an ancient town of European Turkey, in Romania, fifty-six miles N. E. of Gallipoli.

GONIOMETRICAL, [from *γωνια*, an angle, and *μετρον*, to measure,] belonging to the measurement of angles.

GONIOMETRICAL LINES, in geometry, lines used for determin-

ing the quantity of angles; such as sines, tangents, secants, &c. A paper on this subject is inserted in the Philosophical Transactions, No. 483, § 26.

GONIOMETRY, the art or method of measuring angles. M. De Lagny presented several papers on this art to the Royal Academy, which are inserted in their Memoirs for 1724, 1725, and 1729. His method consists in measuring the angles with a pair of compasses, without any scale, except an undivided semicircle. But as it appears not to have been adopted by any succeeding mathematicians, and has been reckoned of very little value by some, we shall refer the inquisitive reader for a farther description of it to the Academy's Memoirs, or Dr. Hutton's Mathematical Dictionary.

GONIUM, a genus of vermes, of the order infusoria. Worm very simple, flat, angular, invisible to the naked eye. There are five species. The pectoral, quadrangular, pellucid, with sixteen spherical molecules, found in pure water; molecules oval, nearly equal in size, set in a quadrangular membrane, like diamonds in a ring, the lower ones a little larger than the rest.

GONZAGA, or **GONZAGO**, **LUCRETIA**, one of the most illustrious ladies of the sixteenth century; much celebrated for her wit, learning, and delicate style. Hortensio Lando wrote a panegyric upon her, and dedicated to her his dialogue of moderating the passions. Her letters were collected and published at Venice in 1552. She was married, when she was not fourteen years of age, to John Paul Manfrone, who afterwards engaged in a conspiracy against the duke of Ferrara; was detected and imprisoned, but, though condemned, not put to death. She did all in her power to obtain his liberty, but in vain; for he died in prison, having shewn such impatience under his misfortunes, as made it imagined he lost his senses. She never would listen afterwards to any proposals of marriage, though several were made to her. All that came from her pen was so much esteemed, that a collection was made even of the notes she wrote to her servants.

GOODENIA, a genus of the pentandria monogynia class and order. The corolla is five-cleft; anthers linear; stigma cup-shaped, ciliated; capsule two-celled, two-valved. Seeds many, imbricated. There are nine species, shrubs of South Wales.

GOOD BEHAVIOUR, in law, an exact carriage and behaviour to the king and the people. A justice of the peace may, at the request of another, or where he himself sees cause, demand surety for the good behaviour; and to that end the justice may issue out his warrant against any persons whatsoever, under the degree of nobility; but when it is a nobleman, complaint is to be made in the court of chancery, or king's bench, where such nobleman may be bound to keep the peace. Infants and femmes couvertes, who ought to find surety by their friends, may be bound over to their good behaviour; also lunatics, who have sometimes lucid intervals, and all others who break the peace, or are suspected to do it by affrays, assaults, battery, wounding, fighting, quarrelling, threatening, &c. Persons may be likewise bound to good behaviour for a scandalous way of living, keeping bawdy-houses, gaming-houses, &c. and so may common drunkards, whoremongers, common whores, cheats, libellers, &c. He who demands surety for the peace, on any violence offered, must take an oath before the justice, that he goes in fear of his life, or some bodily harm, &c. and that it is not out of malice, but from a regard to his own safety.

GOOD FORTUNE, an island in the E. Sea, called also Pora, near the W. coast of Sumatra, thirty-six miles long, and six broad. Lon. 98. 30. E. Lat. 15. S.

GOOD FRIDAY, a fast of the Christian church, in memory of the sufferings and death of Jesus Christ. It is observed on the Friday in holy or passion week. Among the Saxons it was called Long Friday; probably on account of the long fastings, &c. then used.

GOOD HOPE, **CAPE OF**, a promontory of Africa, where the Dutch built a good town and fort. It now belongs to the English. The Cape lies west of Cape Lagullas, the most southern extremity of Africa. Lon. 18. 23. E. Lat. 34. 29. S.

GOODWIN SANDS, or **GODWIN SANDS**, famous sandbanks off the coast of Kent, lying between the north and south Foreland.

GOOGINGS, in sea-language, are clumps of iron bolted on the stern-post of a ship, whereon to hang the rudder, and keep it steady; for which purpose there is a hole in each of them, to receive

ceive a correspondent spindle bolted on the back of the rudder, which turns thereby as upon hinges.

GOOSE, in ornithology. See ANAS.

GOOSE, EMBER, a peculiar species of geese that frequent the coasts of the Orkney and Shetland isles in the winter, described by the rev. Mr. Bremner, in his account of Walls and Flota.

GOOSEBERRY, in botany. See RIBES.

GOOSEBERRY, AMERICAN. See MELASTOMA.

GOOSEBERRY, BARBADOES. See CACTUS.

GOOSEFOOT. See CHENOPodium.

GOOSEGRASS. See GALIUM.

GOOSE-NECK, in a ship, a piece of iron fixed on the one end of the tiller, to which the lanyard of the whip-staff or the wheel-rope comes, for steering the ship.

GOOSE-WING, in sea-language. When a ship sails before, or with a quarter-wind on a fresh gale, to make the more haste, they launch out a boom and sail on the lee-side; and a sail so fitted, is called a goose-wing.

GOOTY, or GUTTI, a strong fort of Hindostan, 25 miles S. by E. of Adoni. Lon. 77. 35. E. Lat. 15. 15. N.

GORCUM, or GORICHEM, a town of Batavia, in the department of Delft, and late province of Holland, 12 miles E. of Dort, and 30 S. of Amsterdam.

GORDIAN KNOT, in antiquity, a knot made by king Gordius, in one of the cords of his yoke, or as some have it, in the leathers of his chariot-harness; which was so very intricately twisted that it was impossible to discover where it began or ended. The oracle of Apollo having declared that whoever should untie this knot should be master of all Asia, many attempted it, but without success; till at last Alexander the Great, after likewise attempting in vain to untie it, cut it asunder with his sword, and thus either eluded or fulfilled the prediction.

GORDIUS, in fabulous history, a poor husbandman who had two yokes of oxen, wherewith he ploughed his land and drew his wain. An eagle sitting a long while upon one of his oxen, he consulted the soothsayers; a virgin bad him sacrifice to Jupiter in the capacity of king. He married the virgin, who bore to him Midas. The Phrygians instructed by the oracle to set the first person they met in a wain upon the throne, met Gordius, and made him king. Midas for this good fortune dedicated to Jupiter his father's cart; and Gordius hung up the knot of the yoke in the temple. See GORDIAN KNOT.

GORDIUS, HAIR-WORM, in natural history, a genus of the vermes intestina class and order. Body round, filiform, equal, smooth. There are five species.

G. AQUATICUS, is from four to six inches long, of a pale brown colour, but darker at the extremities: it is found in stagnant waters, and twists itself into various contortions and knots, and it is said that if it is handled without caution, it will inflict a bite that occasions the whitlow.

GORDON, ALEXANDER, M.A. an eminent Scotch antiquary, an excellent draughtsman, and a good Greek scholar, who resided many years in Italy, visited most parts of that country, and travelled into France, Germany, &c. He was secretary to the Society for Encouragement of Learning; and afterwards to the Egyptian Club, composed of gentlemen who had visited Egypt such as Lord Sandwich, Dr. Shaw, Dr. Pococke, &c. He succeeded Dr. Stukely as secretary to the Antiquarian Society, which office he resigned in 1741 to Mr. Joseph Ames. He went to Carolina with governor Glen, where, besides a grant of land, he had several offices, such as register of the province, &c. and died a justice of the peace, leaving a handsome estate to his family. He published, 1. Itinerarium Septentrionale, or a Journey through most parts of the Counties of Scotland, in two parts, with sixty-six copperplates, 1726, folio. 2. Supplement to the Itinerarium, 1732, folio. 3. The Lives of Pope Alexander VI. and his son Caesar Borgia. 4. A complete History of the ancient Amphitheatres, 1730, 8vo. afterwards enlarged in a second edition. 5. An Essay towards explaining the hieroglyphical Figures on the Coffin of the ancient Mummy belonging to Captain William Lethieullier, 1737, folio, with cuts. 6. Twenty-five plates of all the Egyptian Mummies and other Egyptian Antiquities in England, 1739, folio.

GORDONIA, LOBLOLLY-BAY; in botany, a genus of the monodelphia polyandria class and order. Natural order, Columnifera.

Calyx five-leaved; petals five, united at the base by means of the nectary; filament inserted into the nectary; capsule superior, five-celled; seeds winged. There are three species.

GORÉ, in heraldry, one of the abatements, which, according to Gullim, denotes a coward. It is a figure consisting of two arch-lines drawn one from the sinister chief, and the other from the sinister base, both meeting in an acute angle in the middle of the fess-point. See HERALDRY.

GORÉE, a small island of Africa, near Cape de Verd. Lon. 17. 25. W. Lat. 14. 40. N.

GORÉE, an island of Batavia, in the department of Delft, near the mouth of the Meuse.

GORÉE, the capital of the above island, 6 miles S. of Helvoetsluys.

GOOREY, a borough and post town of Ireland, in Wexford, otherwise called Newborough, 18 miles N. of Wexford.

GORGE, in architecture, the narrowest part of the Tuscan and Doric capitals, lying between the astragal, above the shaft of the pillar and the annulets.

GORGE, in fortification, the entrance of the platform of any work. See FORTIFICATION.

GORGED, in heraldry, the bearing of a crown, coronet, or the like, about the neck of a lion, a swan, &c. The term is also used when the gorge or neck of a peacock, swan, or the like bird, is of a different colour or metal from the rest.

GORGET, a kind of breast-plate like a half-moon, with the arms of the prince thereon; worn by the officers of foot.

GORGON, [*γοργων*], a monster with snaky hairs, of which the sight turned the beholders to stone; any thing ugly or horrid. The Gorgons, in antiquity and mythology, were three sisters, whose names were Stheno, Boryale, and Medusa; the latter of whom was mortal, but the two former were subject to neither age nor death. They are described with wings on their shoulders, with serpents round their heads, their hands were of brass, and their teeth of a prodigious size, so that they were objects of terror to mankind.

GORGONIA, in natural history, a genus of the vermes zoophyta class and order. Animal growing in the form of a plant; stem coriaceous, corky, woody, horny, or bony, composed of glassy fibres, or like stone, striate, tapering, dilated at the base, covered with a vascular or cellular flesh or bark, and becoming spongy and friable when dry; mouths or florets covering the surface of the stem and polype-bearing. There are about forty species.

GORHAM, a kingdom of Africa lying between Lon. 24° and 29° E. and between Lat. 10° and 15° N.

GORTIA, GORTITZ, or GORZ, a county of Austria.

GORTIA, or GORTITZ, a strong town in the above county, with a castle. It is 20 miles N. E. of Aquileia.

GORLITZ, a strong town in Upper Lusatia, 50 miles W. of Dresden.

GORTA, or St. MARIA LA GORTA, an island in the Pacific Ocean. Lon. 135. 0. W. Lat. 26. 35. N.

GORTERIA, in botany, a genus of the polygamia frustranea order, and syngenesia class of plants; natural order, Compositæ. Character: calyx imbricate, with spiny scales; corolla of the ray ligulate; down woolly; receptacle naked. There are thirteen species, mostly shrubby plants from the Cape of Good Hope.

GOSHEN, in ancient geography, a district of Egypt, which Joseph procured for his father and brethren. It was the most fruitful part of the country; and its name seems to be derived from the Hebrew, Gesham; which signifies "rain;" Calmet thinks that Goshen, which Joshua (x. 41, xi. 16, xv. 51,) makes part of the tribe of Judah, is the same land of Goshen, which was given to Jacob and his sons by Pharaoh. Gen. xlv. 26. It is certain that this country lay between Palestine and the city of Tanais, and that the allotment of the Hebrews reached southward as far as the Nile. Josh. xiii. 3.

GOSHEN, a township of Massachusetts in Hampshire county, 14 miles N. of Northampton.

GOSPEL, the history of the life, actions, death, resurrection, ascension, and doctrine, of Jesus Christ. The word is Saxon, and of the same import with the Latin term *evangelium*, or the Greek *εὐαγγέλιον*, which signifies glad tidings; or good news; the history of our blessed Saviour being the best news ever published to mankind. This history is contained in the writings of St. Matthew, St.

St. Mark, St. Luke, and St. John; who from thence are called evangelists. The Christian church never acknowledged any more than these four gospels as canonical; notwithstanding which, several apocryphal gospels are handed down to us, and others are entirely lost.

GOSPORT, a town of Hampshire, 79 miles from London.

GOSSAMER, the name of a fine filmy substance, like cobwebs, which is seen to float in the air, in clear days in autumn, and is more observable in stubble-fields, and upon furze and other low bushes. This is probably formed by the flying spider, which, in traversing the air for food, shoots out these threads from its arms which are borne down by the dew, &c.

GOSSEINS, a town of Asia in Thibet, on the E. coast of the Dewah.

GOSSLAR, a town of lower Saxony. Lon. 5. 37. E. Lat. 51. 55. N.

GOSSYPIMUM, **COTTON**; a genus of the polyandria order, and monadelphia class of plants; natural order, Columniferae. Calyx double, the exterior one trifold; capsule quadrilocular; seeds wrapt in cotton-wool. It has six species natives of warm climates. Cotton-plants are cultivated in great quantities in fields for the sake of the cotton: but the herbaceous species is most generally cultivated. The pods are sometimes as large as middling-sized apples, closely filled with the cotton surrounding the seed. When these plants are raised in this country, they must be continually kept in a warm stove, where they will produce seeds and cotton. They are propagated by seeds. The American Islands produce cotton-shrubs of various sizes, which rise and grow up without any culture; especially in low and marshy grounds. Their produce is of a pale red; some paler than others; but so short that it cannot be spun. None of this is brought to Europe, though it might be usefully employed in making hats. The cotton-shrubs, that supply our manufactures, require a dry and stony soil, and thrive best in grounds that have been tilled.

GOTHA, a city of Germany, in Upper Saxony. It is eighteen miles W. of Erfurt. Lat. 50° 56' 17" N. Lon. from Greenwich 10° 41' 46" E.

GOTHARD, **ST** one of the highest mountains of Switzerland. From the top, where there is an hospital for travellers, and a monastery for monks, is one of the most pleasing prospects in the world. It is eight miles from Altorf, and is situated in the canton of Uri, on the confines of the Vallais, the Grisons, and Italy. Its ancient name, according to Ptolemy and Strabo, was Adula.

GOTHIC STILE, in architecture. See **ARCHITECTURE**.

GOTHLAND, the most southern province of Sweden. It contains 48 towns, and is divided into E. S. and W. Gothland.

GOTHLAND, EAST, or **OSTROGOTHIA**, a province of Sweden, bounded on the E. by the Baltic, S. by Smaland, W. by the Wetter lake, which divides it from W. Gothland, and on the N. by Nericia and Sundermantand. The chief towns are Nordkiöping, Söderkiöping, Linköping, and Wadstena.

GOTHLAND, SOUTH, a country of Sweden, which is divided into three provinces, viz. Schonen, Halland, and Blekingen.

GOTHLAND, WEST, or **WESTROGOTHIA**, a province of Sweden, bounded on the E. by Nericia, Wetter Lake, and Smaland; S. by Smaland and Halland; W. by the Scaggerac; and N. by Warmeland. Gothland is fertile in corn and fruits, and has excellent pastures. The rivers, lakes, and sea-coast, abound with fish. Iron, alum, &c. are manufactured by the natives.

GOTHLAND, or **GOTTLAND**, an island of Sweden, in the Baltic, 70 miles long, and no where above 25 broad. Wisby is the capital. Lon. from 18. 6. to 19. 6. E. Lat. from 56. 54. to 57. 56. N.

GOTHS, a warlike nation, famous in the Roman history, who came originally out of Scandinavia, the name given by the ancients to Sweden, Norway, Lapland, and Finmark. According to the most probable accounts, they were the first inhabitants of those countries; and from thence sent colonies into the islands of the Baltic, the Cimbric Chersonesus, and the adjacent places. The time of their first settling in Scandinavia, and of their first peopling the abovementioned islands and Chersonesus, are equally uncertain; though the Gothic annals state the latter to have happened in the time of Serug the great grandfather of Abraham. This first migration of the Goths is said to have been conducted by their king Eric; in which all the ancient Gothic chronicles, as well as the Danish and Swedish ones, agree. Their second migration is said to have happened many ages after; when, being overstocked

with people, Berig, then king of the Goths, went out with a fleet in quest of new settlements. He landed in the country of the Ulmerugians, now Pomerania, drove out the ancient inhabitants, and divided their lands among his followers. The Goths, who settled in Pomerania and the adjacent parts of Germany, being greatly increased, they undertook a third migration in great numbers under Filimer the Great, their fifth prince after leaving Scandinavia; and taking their route eastward, entered Scythia, advanced to the Cimmerian Bosphorus, and driving out the Cimmerians, settled near the Palus Maotis. Thence in process of time, being greatly increased in Scythia, they resolved to seek new settlements; and accordingly taking their route eastward, they traversed several countries, and at length returned into Germany. Their leader in this expedition was the celebrated Woden. The Romans distinguished the Goths into two classes; the Ostrogoths and Visigoths. These names they received before they left Scandinavia, the Visigoths being softened by the Latins from Westergoths, or those who inhabit the western part of Scandinavia, as the Ostrogoths were those who inhabited the eastern part of that country. After the destruction of the Roman empire by the Heruli, the Ostrogoths, under Theodoric, became masters of the greatest part of Italy, having overcome and put to death Odoacer king of the Heruli in 494. They retained their dominion in this country till A. D. 553; when they were finally conquered by Narses, Justinian's general. The Visigoths settled in Spain in the time of Honorius, where they founded a kingdom which continued till the country was subdued by the Saracens. The Goths were famous for their hospitality and kindness to strangers, even before they embraced Christianity. Nay, it is said, that from their being eminently good, they were called Goths, by the neighbouring nations; that name, according to Grotius and most other writers, being derived from the German word *guten*, which signifies good. They encouraged, says Dio, the study of philosophy above all other barbarous or foreign nations, and often chose kings from among their philosophers. Polygamy was not only allowed but countenanced among them: every one being valued or respected according to the number of his wives.

GOTTENBURG, or **GOTHENBORG**, a rich and strong town of Sweden, in W. Gothland, with a good harbour, at the mouth of the Gøthelba. Lon. 11. 50. E. Lat. 57. 42. N.

GOTTINGEN, a considerable town of Lower Saxony in the duchy of Brunswick. Lon. 10. 5. E. Lat. 51. 32. N.

GOTTINGEN, a town of Sweden, 28 miles S. W. of Stockholm. The latitude of the observatory is 51° 31' 54" N. and its longitude from Greenwich 9° 54' 15" E.

GOTTORP, a town of Denmark, in the duchy of Sleswic, capital of Holstein Gottorp.

GOUANIA, in botany, a genus of the monœcia order, and polygamia class of plants. Hermaphrodite, quinquefid; calyx no corolla; style trifid; the fruit, inferior to the receptacle of the flower, divisible into three seeds. The male is like the hermaphrodite, but wanting stigma and germen.

GOUDA, or **TURGOW**, a considerable town of Batavia in the department of Delit, and late province of S. Holland, 9 miles N. E. of Rotterdam.

GOUDHURST, a town of Kent, 12 miles S. W. of Maidstone, and 44 S. E. of London.

GOVERNMENT, in general, is the polity of a state, or an orderly power constituted for the public good. Civil government was instituted for the preservation and advancement of men's civil interests, and for the better security of their lives, liberties, and properties. The use and necessity of government is such, that there never was an age or country without some sort of civil authority: but as men are seldom unanimous in the means of attaining their ends, so their difference in opinion in relation to government, has produced a variety of forms of it. To enumerate them, would be to recapitulate the history of the whole earth. But they may, in general, be reduced to one of these heads: either the civil authority is delegated to one or more, or else it is still reserved to the whole body of the people; whence arises the known distinction of government into monarchy, aristocracy, and democracy. See **ARISTOCRACY**, **DEMOCRACY**, **FEODAL SYSTEM**, &c. Governments are commonly divided into two classes, arbitrary and free governments; but there are many different sorts of each. Thus the governments of France and Spain, are generally called arbitrary; though they differ as much from the governments of Turkey and other eastern empires, where absolute despotism prevails, as they

they do from the government of England, and other European nations, where liberty is said to flourish in its fullest perfection.

GOVERNMENT is also used for a post or office, which gives a person the power or right to rule over a city, or a province, either supremely or by deputation.

GOVERNMENT is likewise used for the city, country, or place, to which the power of governing is extended.

GOVERNOLO, a town of the late Cisalpine republic, in the department of Mincio, and late duchy of Mantua, 12 miles S. E. of Mantua.

GOUGE, is a round hollow chisel, serving to cut holes, channels, grooves, &c. in wood, stone, &c.

GOURD, in botany. See **CUCURBITA**.

GOURD, BITTER. See **CUCUMIS**.

GOURD, ETHIOPIAN SOUR. See **ADANSONIA**.

GOURDON, a town of France, in the department of Lot, 17 miles N. of Cahors.

GOURNAY, a town of France, in the department of Lower Seine, and late duchy of Normandy. It is 52 miles N. W. of Paris.

GOUT. See **MEDICINE**. In the new system of medicine, the gout is considered as a disease not arising from plethora, but from the very opposite cause, viz debility; and therefore to be cured by means the reverse of those formerly too generally prescribed.

GOUTWORT. See **ÆGOPodium**.

GOWER, JOHN, one of the most ancient English poets, was contemporary with Chaucer, and his intimate friend. He studied the law, and was some time a member of the society of Lincoln's-inn. Some have asserted that he was a judge. In the first year of Henry IV. he became blind, which he laments in one of his Latin poems. He died in 1402; and was buried in St. Mary Overie, which church he had rebuilt chiefly at his own expence, so that he must have lived in affluent circumstances. His tomb was magnificent, and curiously ornamented. It still remains, but has been repaired in later times. From the collar of SS round the neck of his effigies, which lies upon the tomb, it is supposed that he had been knighted. With regard to his poetical talents, it is sufficient to say, that he was admired at the time when he wrote. He wrote, 1. *Speculum Meditantis*, in French, in ten books. There are two copies of this in the Bodleian library. 2. *Vox Clamantis*, in Latin verse, in seven books. Preserved also in the Bodleian library, and in that of All-souls. It is a chronicle of the insurrection of the commons in the reign of Richard II. 3. *Confessio Amantis*; printed at Westminster by Caxton in 1493, London 1532, 1545. It is a sort of poetical system of morality, interspersed with a variety of moral tales. 4. *De Rege Henrico IV.*; printed in Chaucer's works. There are likewise several historical tracts, in MS. written by our author, which are to be found in different libraries; also some short poems printed in Chaucer's works.

GOWER'S ISLAND, an isle in the S. Pacific ocean, which has no anchorage near it. Lon. 158. 56. E. Lat. 7. 55. S.

GOWRAN, a borough and post town of Ireland, in Kilkenny, 52 miles from Dublin.

GOZA, or **GOZZO**, an island of the Mediterranean, four miles and a half from Malta, and 24 in circumference. It is supposed to be the island of Calypso, celebrated by Homer.

GOZZO DI CANDIA, an island of the Mediterranean near Candia.

GRACE, among divines, is taken, 1. For the free love and favour of God, which is the spring and source of all the benefits we receive from him. 2. For the work of the Spirit renewing the soul after the image of God; and continually guiding and strengthening the believer to obey his will, and to resist and overcome sin.

GRACE, or **GRACEFULNESS**, in the human character, is an agreeable attribute, inseparable from motion as opposed to rest, and as comprehending speech, looks, gesture, and loco-motion. As some motions are homely, the opposite to graceful, it may be inquired, With what motions is this attribute connected? No man appears graceful in a mask; and therefore, laying aside the expressions of the countenance, the other motions may be genteel, may be elegant, but of themselves never are graceful. A motion adjusted in the most perfect manner to answer its end is elegant;

VOL. II.—NO. 98.

but still somewhat more is required to complete our idea of grace or gracefulness. What this more may be, is the nice point. One thing is clear from what is said, that it must arise from the expressions of the countenance: and from what expressions so naturally as from those which indicate mental qualities, such as sweetness, benevolence, elevation, dignity? This promises to be a fair analysis; because of all objects mental qualities affect us the most; and the impression made by a graceful appearance, upon every spectator of taste, is too deep for any cause purely corporeal. The next step is, to examine what are the mental qualities, that, in conjunction with elegance of motion, produce a graceful appearance. Sweetness, cheerfulness, affability, are not separately sufficient, nor even in conjunction. Dignity alone, with elegant motion, produce a graceful appearance; but still more graceful with the aid of other qualities, those especially that are the most exalted. But this is not all. The most exalted virtues may be the lot of a person whose countenance has little expression; but such a person cannot be graceful. To produce this appearance, must be added, an expressive countenance, displaying to every spectator of taste, with life and energy, every thing that passes in the mind. Collecting these circumstances together, grace may be defined, "that agreeable appearance, which arises from elegance of motion, and from a countenance expressive of dignity." Expressions of other mental qualities are not essential to that appearance, but they heighten it greatly. See **DECLAMATION** and **ORATORY**. But in vain will a person attempt to be graceful who is deficient in amiable qualities. A man, it is true, may form an idea of qualities he is destitute of; and, by means of that idea, may endeavour to express these qualities by looks and gestures; but such studied expression will be too faint and obscure to be graceful.

GRACE, ACT OF, the appellation given to the act of parliament, 1696, c. 32, which allows prisoners for civil debts to be set at liberty, upon making oath that they have not wherewithal to support themselves in prison, unless they are alimanted by the creditors on whose diligence they were imprisoned, within ten days after intimation made for that purpose.

GRACE, DAYS OF, three days immediately following the term of payment of a bill, within which the creditor must protest it, if payment is not obtained, in order to entitle him to recourse against the drawer.

THE GRACES, GRATIE, or CHARITES, in the heathen theology, were fabulous deities, three in number, who attended on Venus. Their names are, Aglaia, Thalia, and Euphrosyne; i. e. shining, flourishing, and gay; or, according to some authors, Pasithea, Euphrosyne, and Ægiale. They were said by some to be the daughters of Jupiter, by Eurynome the daughter of Oceanus; and by others, of Bacchus and Venus. Some will have the Graces to have been four; and make them the same with the Horæ, Hours, or rather with the four seasons of the year.

GRACILIS, a muscle of the leg, so called from its slender shape. See **ANATOMY**.

GRACULA, the GRAKLE; in ornithology, a genus of the order picæ. Bill convex, thick, sharp-edged, somewhat naked at the base; nostrils small, near the base of the bill; tongue entire, rather sharp at the end; claws hooked and sharp. There are thirteen species, none of them found in Europe. *G. kelegiosa*, or the minor grakle, is of the size of a blackbird, is found in various districts of the East Indies, and almost in every island beyond the Ganges. It is rendered familiar with the greatest ease, and taught to speak with greater facility than even the parrot; and also pronounces its words with more distinctness.

GRADATION, in logic, a form of reasoning, otherwise called **Sorites**. See **LOGIC** and **SORITES**.

GRADATION, in painting, a gradual and insensible change of colour, by the diminution of the tints and shades.

GRADATION, in rhetoric, the same with **Climax**. See **CLIMAX**.

GRADISCA, GRADISG, or GRADISKA, a town of Sclavonia, on the borders of Croatia, 20 miles S. W. of Posega.

GRADISCA, or GRADISKA, a town of Germany, in Austria, 5 miles S. of Goritz.

GRADO, a podestaria or district of Maritime Austria, in the Dogado of Venice, including several lakes and islands.

GRADUATE, a person who has taken a degree in the university. See **DEGREES**.

Z X

GRADUATION,

GRADUATION, in mathematics, the act of graduating or dividing any thing into degrees or equal parts.

GRAFF, or **GRAFT**, [*greffe*, Fr.] a small branch inserted into the stock of another tree, and nourished by its sap, but bearing its own fruit; a young cyon.

GRAFTING, or **ENGRAFTING**, in gardening, the taking of a shoot from one tree, and inserting it into another, so that they may closely unite, and form one trunk. Grafting has been practised from the most remote antiquity; but its origin and invention are differently related by Naturalists. The great aim of this useful art is, to propagate any curious sorts of fruit-trees, to insure the growth of similar kinds, which cannot be effected by any other method: for, as all the good species of fruit have been accidentally obtained from seeds, many of these, when sown, will degenerate, and produce bad fruit. But, when shoots are taken from such trees as bear good fruit, they will never change their kind, whatever be their stock, or the tree on which they are grafted. Mr. Bradley observes, that the stock grafted on, is only to be considered as a fund of vegetable matter, which is to be filtered through the cyon, digested, and brought to maturity, as the time of growth in the vessels of the cyon directs. A cyon, therefore, of one kind, grafted on a tree of another, may be rather said to take root in the tree it is grafted, than to unite with it: for it is obvious that the cyon preserves its natural purity, though it be fed and nourished by a mere crab. The grafts or cyons with which this operation is effected, should be of the last summer's growth, from the outside branches; firm and well-ripened; and selected from healthy trees. The graft is always the middle part of each shoot, cut to five or six inches in length, or so as to have four or five good eyes, or buds, but should be preserved at full length, till grafting time. The proper tools and other materials used in grafting, are: 1. A strong knife for cutting off the heads of the stocks, previous to the insertion of the graft; also a small hand-saw, for occasional use, in cutting off the heads of large stocks; 2. A common grafting-knife, or strong sharp penknife, for cutting and shaping the grafts ready for insertion; also to slope and form the stocks for the reception of the cyons; 3. A flat grafting-chisel, and small mallet for clefting large stocks, in cleft-grafting; 4. A quantity of new bass-strings for bandages, for securing the grafts, and promoting their speedy union with the stock; and 5. A quantity of clay, for applying closely round the grafts after their insertion and binding, to defend the parts from the influence of the sun, winds, and wet weather, or from being affected by cold. For this purpose a kind of stiff loamy mortar may be prepared of strong fat loam; or any other tough clay may be substituted; to which may be added a fourth part of fresh horse-dung, free from litter, and a small portion of cut hay, with a little water, well mixed: the whole should be properly beaten with a stick, and thus incorporated. This operation should be repeated, according to the nature of the clay, and performed several times during the first day; the composition being still moistened with water for six or seven days successively, at the end of which time it will be fit for use. There are various other modes of engrafting, which are termed whip-grafting, or tongue-grafting, cleft-grafting, crown-grafting, root-grafting, cheek-grafting, side-grafting; and, lastly, grafting by approach, or inarching. The following are most commonly and successfully practised:

1. **WHIP-GRAFTING**, or **TONGUE-GRAFTING**, is generally performed in nurseries, upon small stocks, from a quarter of an inch to half, or a whole inch in diameter. The stock, and cyons or grafts, should in every instance be of the same size or approach as nearly to the same size as possible. They are both to be sloped off a full inch, or more, and then tied closely together. This method may be much improved, by performing what gardeners call tongueing, or tipping; that is, by making an incision in the bare part of the stock, downwards, and a similar slit in the cyon, upwards; after which they are to be carefully joined together, so that the rinds of both may meet in every part, when a ligament or bandage of bass is to be tied round the cyon, to prevent it from being displaced; and the whole is to be covered over, or coated, with the clay above described.

2. **CLEFT-GRAFTING**, or **SLIT-GRAFTING**, as gardeners differently term it, is performed upon stocks from one to two inches in diameter. The head of the stock being carefully cut off, in a sloping direction, a perpendicular cleft, or slit, is to be made

about two inches deep, with a knife or chisel, towards the back of the slope, into which a wedge is to be driven, in order to keep it open for the admission of the cyon: the latter must now be cut in a perpendicular direction, and in the form of a wedge, so as to fit the incision in the stock. As soon as it is prepared, it should be placed in the cleft, in such a manner that the inner bark of both the stock and cyon may meet exactly together. It is then to be tied with a ligature of bass, and clayed over, as is practised in whip-grafting, three or four eyes being left on the cyon uncovered. The proper season for this mode of grafting is the same as for the preceding, viz. the months of February and March: towards the latter end of May, or the beginning of June, the junction of the graft and stock will be completed, and the latter begin to shoot; when the clay may be taken off, and, in the course of a fortnight or three weeks, the bandages may be removed.

3. **APPROACH-GRAFTING**, or **INARCHING**, is performed in April or May, when the stock we would graft, and the tree we would propagate, grow so near together, as to be conveniently in contact, and the nearer the graft and the stock are of a size the better. This mode of propagation is esteemed the surest of all; and in truth, some things cannot be so well propagated any other way. It is a method that is, or can be, seldom used for common fruit-trees; but if any one wishes to try the experiment, the stock or stocks must be planted at least a year before, first making the soil good, as it may need it, being so near another tree, for it of course must be close. Plants in pots or tubs, being easily brought together, are frequently propagated this way; so that inarching is used much in greenhouses and hot-houses for various things, as oranges, lemons, pomegranates, jasmynes, and vines sometimes; oranges and lemons thus treated in May will be united by August. The method of inarching is this, bend the best-situated young branch of the tree or shrub to be propagated, to the stock to be grafted, and having determined on the part at which most conveniently to fix the shoot, cut the bark of that part of the shoot off, with nearly half the wood (not to touch the pith) to the length of about three inches for a strong branch, or less for a weaker. Then cut exactly so much of the bark and branch of the stock off, as will receive the cut part of the branch or shoot, so as to bring bark and bark in contact in every part; and if the contrivance of lipping is used, it will secure them better together. Bind and clay, and if in open ground, fix a stake to tie the work so that the wind may have no power over it; a tie also to a neat stick may be proper for those inarched in pots, &c. By this kind of grafting may be raised almost any kind of tree or shrub, which is often done by way of curiosity, to ingraft a fruit-bearing branch of a fruit-tree upon any common stock of the same genus, whereby a new tree bearing fruit is raised in a few months. This is sometimes practised upon orange and lemon-trees, &c. by grafting bearing branches of a fruit-tree upon any common stocks raised from the kernels of any of the same kind of fruit, or into branches of each other, so as to have oranges, lemons, and citrons, all on the same tree.

GRAFTON, RICHARD, an English historian, born at London, in the reign of Henry VIII. He published, 1. An Abridgement of the Chronicles of England; and, 2. A Chronicle and large History of the Affayres of England and Kings of the same, deduced from the Creation of the World. He died in the reign of Queen Elizabeth.

GRAFTON, an extensive county of New Hampshire, bounded on the E. by Maine District, S. by Strafford, Hillsborough, and Cheshire counties; W. by Vermont, and N. by Canada.

GRAFTON, a township of the above county, 13 miles S. E. of Dartmouth, and 19 S. W. of Plymouth.

GRAFTON, or **GRAFTON ISLAND**, one of the Bashee islands in the East Indian Sea. Lon. 120. 55. E. Lat. 21. 4. N.

GRAHAM, GEORGE, clock and watch-maker, the most ingenious and accurate artist in his time, was born in 1675. After his apprenticeship, Mr. Tompson received him into his family, purely on account of his merit; and treated him with a kind of parental affection as long as he lived. Besides his universally acknowledged skill in his profession, he was a complete mechanic and astronomer: the great mural arch in the observatory at Greenwich was made by Dr. Halley, under his immediate inspection, and divided by his own hand; and from this incomparable original, the best foreign instruments of the kind are copies made by English artists. The sector, by which Dr. Bradley first discover-

ed two new motions in the fixed stars, was of his invention and fabric; and when the French academicians were sent to the north to ascertain the figure of the earth, Mr. Graham was thought the fittest person in Europe to supply them with instruments: those who went to the south were not so well furnished. He was for many years a member of the Royal Society, to which he communicated several ingenious and important discoveries; and regarded the advancement of science more than the accumulation of wealth. He died in 1751.

GRAIN, all sorts of corn, as wheat, barley, oats, rye, &c.

GRAIN is also the name of a small weight, the twentieth part of a scruple in apothecaries weight, and the twenty-fourth of a penny-weight troy. See the article **WEIGHT**. A grain-weight of gold-bullion is worth two-pence, and that of silver but half a farthing.

GRAIN also denotes the component particle of stones and metals, the veins of wood, &c. Hence cross-grained, or against the grain, is contrary to the fibres of wood, &c.

GRAINING-BOARD, among curriers, an instrument called also a pummel, used to give a grain to their leather.

GRAITNEY GREEN, a village of Scotland in Dumfriesshire, long famous for the clandestine marriages of young persons of fortune from England; performed according to the rites of the church of England, by a blacksmith, who is said to gain near 1,000l. a-year by this encroachment on the clerical office.

GRALLÆ, in ornithology, an order of birds analogous to the bruta in the class of mammalia, in the Linnæan system. See **ZOOLOGY** and **ORNITHOLOGY**.

GRAMAT, a town of France, in the department of Lot; 8 miles S. W. of St. Cere and 2½ N. N. E. of Cahors.

GRAMAYE, JOHN BAPTIST, a historian and poet, born at Antwerp, and provost of Arnhem. He travelled over Germany and Italy, but in going to Spain, was carried off by African corsairs to Algiers. He returned to the Netherlands, and died at Lubek. He published, 1. *Africa illustrata*, libri X. in 1622; 4to. 2. *Diarium Algeriense*; 3. *Peregrinatio Belgica*: a curious work; 4. *Antiquitates Flandriæ*; fol. and, 5. *Historia Namurcensis*.

GRAMINA, GRASSES; one of the seven tribes or natural

families, into which all vegetables are distributed by Linnæus in his *Philosophia Botanica*. They are defined to be plants which have very simple leaves, a jointed stem, a husky calyx termed gluma, and a single seed. This description includes the several sorts of corn as well as grasses. In Tournefort they constitute a part of the 15th class, termed apetal; and in Linnæus's sexual method, they are mostly contained in the second order of the third class, triandria digynia. This numerous and natural family of the grasses has engaged the attention and researches of several eminent botanists; particularly Ray, Monti, Micheli, and Linnæus. M. Monti, in his *Catalogus Stirpium Agri Bononiensis*, *Gramina ac hujus Modi Affinia complectens*, printed at Bononia in 1719, divides the grasses from the disposition of their flowers, as Theophrastus and Ray had done before him, into three sections or orders—These are, 1. Grasses having flowers collected in a spike. 2. Grasses having their flowers collected in a panicle or loose spike. 3. Plants that in their habit and external appearance are allied to the grasses. This class would have been natural if the author had not improperly introduced sweet-rush, juncus, and arrow-headed grass, into the third section. Monti enumerates about 306 species of the grasses, which he reduces under Tournefort's genera; to these he added three new genera. Scheuchzer, in his *Aristographia*, published likewise in 1719, divides the grasses, as Monti, from the disposition of their flowers, into the five following sections: 1. Grasses with flowers in a spike, as phalaris, anthoxanthum, and frumentum. 2. Irregular grasses, as schoenanthus and cornucopia. 3. Grasses with flowers growing in a simple panicle or loose spike, as reed and millet. 4. Grasses with flowers growing in a compound panicle, or diffused spike, as oats and poa. 5. Plants by their habit nearly allied to the grasses, as cypress-grass, scirpus, linagrostis, rush, and scuechzeria. He has enumerated about 400 species, which he describes with amazing exactness. Micheli has divided the grasses into six sections, which contain in all 44 genera, and are arranged from the situation and number of the flowers.

GRAMINA, the fourth order in Linnæus's *Fragments of a Natural Method*, consisting of the numerous and natural family of the grasses. See **BOTANY**, and **GRASS**.

GRAMMAR.

GRAMMAR, [*γραμματική*], an art which teaches the several kinds and relations of words, with their propriety, and their disposition into sentences. Grammar is usually divided into four parts. 1. Etymology, which treats of the kinds of words and their derivations. 2. Orthography, which treats of the characters or letters of which words are composed. 3. Syntax, which treats on the right dispositions of words according to their agreement with, and dependencies on, one another in a sentence. 4. Prosody, which treats of the accents and quantity of syllables, and the arrangement of words so as to preserve such a regularity in the accents and quantity as is required in versification.

ETYMOLOGY.

Since words are the signs, by which we express our ideas, they will naturally be of so many kinds in any language as are requisite for doing this intelligibly and with proper dispatch. The objects of our ideas are beings real or imaginary. In order to discourse of these it is requisite that they have names; hence arises a class or kind of words called *nouns*. It is also found necessary in order to discourse intelligibly on beings, to express their properties and the limits of the signification of their names; hence arises another kind of words called very properly *adnouns* or *adjectives*. In pursuing a discourse on any subject, frequent repetitions of the same noun would often be found to occur, and in many cases, except great attention were paid, and circumlocutions used, it would tend to produce ambiguity; hence a third sort of words was introduced, and named *pronouns*, as being intended to stand for nouns, that is, to supply their place, or express the same idea. Since all beings are conceived in the mind as being in some state simply, or as acting, or receiving the impression of some action, it became requisite in good language to have words by means of which these

states and actions might be readily expressed; words used for this purpose are called *verbs*. But as the states and actions which are expressed by verbs, as well as the qualities, which are denoted by adjectives, may be very different according to the circumstances attending them, it has been found convenient to have a class of words to express those circumstances; such words from their principal use are named *adverbs*. The beings of which we discourse, and the state in which they exist, may on different occasions be under such an infinity of circumstances that it would be impossible, as well as inconvenient, to give them different names under these varying circumstances, and the class of adverbs is not sufficient, or always adapted, to express them; hence was wanting a class of connective words, which might serve to join another word to the sentences, and at the same time to exhibit its relation to it, so that the whole may express the beings spoken of in the state and circumstances conceived by the speaker; such words have obtained the appellation of *prepositions*, on account of being generally placed before the nouns they are intended to connect. As in language there is frequent occasion to affirm the same thing of different beings, and also different things of the same being, it was found very convenient to have a class of words to connect such beings or affirmations, since by their means a great multitude of repetitions are avoided: these simple connective words are denominated *conjunctions*. Besides these a few other words, if we may be allowed to call them words, are introduced to express some emotion or feeling of the mind; these have been called *interjections*, as being generally thrown in between the parts of a sentence. Thus in most languages the parts of speech or kinds of words are eight, viz. noun, adjective, pronoun, verb, adverb, preposition, conjunction, and interjection. These different kinds of words are not only convenient for expressing the several ideas we wish to communicate,

municate, but they afford a rich variety in language, as it is evident that by means of them the same ideas may be in many cases designated various ways; which advantage is further increased by the inflections which most languages give to some parts of speech. Of the different ways of expressing our ideas it is the business of the orator to choose the best. It will be unnecessary here to enter into a particular account of each part of speech; the limits of our work will not properly allow it, and sufficient information on this head is generally at hand. We shall therefore only add a few general remarks on some of the principal variations which have been adopted in some of this class of words. Nouns in most languages are changed in their terminations. 1. To express the singular or plural number. 2. To express the difference of sex or gender. 3. To express when the noun is used as a subject or an object: some languages denote this by its place in the sentence. 4. To express those relations, which are otherwise denoted by prepositions. Similar variations are made in adjectives and pronouns, for the same purpose and to make them agree with the varying nouns. Adjectives are also changed in their endings to indicate different degrees of the qualities of nouns. Also the verbs in some languages undergo a great variety of changes to particularize the speaker, and that which is spoken to or of, and the different numbers of each; also to denote the several times and modes of action and of being. The reader, who wishes to enter into a critical examination of the derivations of words, and in what manner the words of one class have been transformed in order to constitute those of another, we refer to the "Diversions of Purley" written by our great philosophical etymologist Mr. Horne Tooke. A judicious enquiry into the etymologies, or derivations, of words, is thought by some of considerable use; because nations, who value themselves upon their antiquity, have always looked on the antiquity of their language as one of the best titles they could plead; and the etymologist, by seeking the true and original reason of the notions and ideas affixed to each word and expression, may often furnish an argument of antiquity, from the traces remaining thereof, compared with the ancient uses. Then that etymologies are necessary for the thorough understanding of a language. It is objected, however, that the art is arbitrary, and built altogether on conjectures and appearances; and the etymologists are charged with deriving their words from where they please; and it must certainly be owned, that etymologies are frequently so far fetched, that one can scarce see any resemblance or correspondence therein. Quintilian has shewn, that the ancient etymologists, notwithstanding all their learning, fell into very ridiculous derivations.

ORTHOGRAPHY.

This part of grammar belongs properly to the elements of words, which are letters, and hence treats of, 1. The number and division of letters. 2. Their accidents. 3. The just manner of writing letters, which, properly speaking, is orthography. 4. The disposition of letters into syllables. And 5. The pronunciation of letters. As to the right letters used in the spelling of words, it must be learned from the best authors in each language. However, it ought to be observed, that orthography has appointed one way of spelling a word in common language, and another in the learned and polite diction: thus, in ordinary, we say, and write, *fancy, fantom, frenzy*, &c. for *phantasy, phantom, phrenzy*, &c. according to the original etymology of these words: and in such cases, as vulgarisms ought to be carefully avoided, so as not to write *obstropolous* for *obstreperous*, and the like; so, on the other hand, we must not alter the received orthography, in imitation of any one man, be his authority or learning ever so great; the general usage being, in this respect, the only rule that ought to be followed, since innovations rather confound than help the learner. We shall therefore only add one observation more, with respect to the orthography of words, viz. that it ought, as much as possible, to be agreeable to the original etymology, sense, and pronunciation, of words: thus it is better to write *phrenzy* than *frenzy*, on account of its being derived from the greek φρεν; in the same manner, the participle of the verb *singe* should be written *singeing*, on account of the sense, to distinguish it from *singing*; and, lastly, when letters are neither necessary on account of the etymology, sense, or sound, they ought to be rejected, as *public* for *publick*, the *k* being wholly superfluous. The rules for the proper disposition of words into syllables must be such as are derived

from the analogy of language in general, or from the established custom of speaking; which, for the English language, are reduced to the following rules: 1. A consonant between two vowels must be joined with the latter in spelling, as *na-ture, ve-ri-ty, ge-ne-rous*: except, however, the letter *x*, which is joined to the first, as in *flax-en, ox-en*, &c. and compound words, as in *up-on, un-used*, &c. 2. A double consonant must be divided, as in *letter, man-ner*, &c. 3. Those consonants which can begin a word, must not be parted in spelling, as in *de-fraud, re-prove, di-stinct*: however, this rule is found sometimes to fail; for though *gn* begins a word, as *gnaw, gnat*, &c. yet it must be divided in spelling, as in *cog-ni-zance, ma-lig-ni-ty*, &c. 4. Those consonants which cannot begin a word must be divided, as *ld* in *sel-dom*, *lt* in *mul-ti-tude*, *mp* in *tem-per*, *rd* in *ar-dent*; but, in final syllables, there are exceptions, as *tl* in *ti-tle*, *dl* in *han-dle*, &c. 5. When two vowels come together, and are both of them distinctly sounded, they must be separated in spelling, as in *co-e-val, mu-tu-al*, &c. 6. The grammatical terminations, or endings, must be separated in spelling, as *ed* in *wing-ed*, *edst* in *de-li-ver-edst*, *ing* in *hear-ing*, *ance* in *de-li-ver-ance*, &c. 7. Compound words must be resolved into their simple or component words, as *up-on, in-to, never-the-less, not-with-stand-ing*, &c. Pronunciation makes much the most difficult part of a written grammar; since a book expressing itself to the eyes, in a matter that wholly concerns the ears, seems next akin to that of teaching the blind to distinguish colours: hence it is that there is no part so defective in grammar as that of the pronunciation, as the writer has frequently no term whereby to give the reader an idea of the sound he would express; for want of a proper term, therefore, he substitutes a vicious and precarious one. To give a just idea of the pronunciation of a language, it seems necessary to fix as nearly as possible all the several sounds employed in the pronunciation of that language. Cicero tells us, that the pronunciation underwent several changes among the Romans; and indeed it is more precarious in the living languages, being, as Du Bos tells us, subservient to fashion in these. The French language is clogged with a difficulty in pronunciation from which most others are free; and it consists in this, that most of their words have two different pronunciations, the one in common prose, the other in verse. As to the pronunciation of the English language, the late Mr. B. Martin, in his Spelling Book of Arts and Sciences, lays down the following rules: 1. The final (*e*) lengthens the sound of the foregoing vowel; as in *can, cane*; *rob, robe*; *tun, tune*, &c. 2. The final (*e*) in words ending in *re*, is sounded before the *r* like *u*; as *nitre, nitur*; *lucre, lu-cur*, &c. 3. The Latin diphthongs *a, æ*, are sounded like *e*; as *Ætna, Etna*; *æconomy, economy*, &c. but at the end of words *oe* sounds like *o*; as in *toe, foe*, &c. 4. Also the English improper diphthongs, *ea, eo, eu, ue*, sound only the *e* and *u*; as *tea or te, feoffee or fessie, due du, true tru*, &c. though sometimes *eo* and *ea* are pronounced like *ee*, as in *people, fear, near*, &c. 5. Sometimes the diphthong (*ie*) is pronounced like *e* in *cieling*, like *ee* in *field*, and, at the end of words, always like *y*; as in *lie*, &c. and *ei* is pronounced either like *e* or *ai*; as in *deceit, reign*, &c. 6. The triphthong *eau* is pronounced like *o*, in *beau* and *jet d'eau*; and *ieu* sound like *u* in *lieu, adieu*, &c. 7. The sound of *c* is hard before the vowels *a, o, u*; as in *call, cold, cup*, &c. also sometimes before *h*, as in *chart, chord*, &c. and before *l* and *r*; as in *cleur, creep*, &c. It is otherwise generally soft, as in *city, cell, cyder, child*, &c. 8. In French words *ch* is sounded like *sh*; as in *chagreen, machine*; and sometimes like *qu*, as in *choir*. 9. The sound of *g* is hard before *a, o, u, l, r*; as in *gall, go, gum, glean, grope*; also before *ui*, as in *guilt, guild*, &c. and before *h*, as in *ghost*; sometimes before *i*, as in *gibbous, gibberish*. It is also generally hard before *e*, as in *get, geld*, &c. but soft in many words derived from the Greek and Latin, as in *geometry, genealogy, genus*, &c. Two *gg* are always hard, as in *dagger*, &c. The sound of *g*, when soft, is like that of *j*. 10. In any part of a word, *ph* sounds like *f*, as in *philosophy*, &c. 11. The sound of *qu*, at the end of French words, is like *k*, as in *risque*, &c. 12. The syllables *ti* and *ci*, if followed by a vowel, sound like *si* or *shi*; as in *fiction, logician*, &c. 13. When *cc* occur before *i*, the first is hard and the latter is soft; as in *flaccid*, &c. 14. The letter *p* is not pronounced at the beginning of syllables, before *s* and *t*; as in *psalm, ptarmics*, &c. As to other peculiarities, regarding single letters, and their pronunciation, many of them have been taken notice of at the beginning of each, in the course of this work.

SYNTAX.

The office of syntax is to consider the natural suitableness of words with respect to one another, in order to make them agree in gender, number, person, mood, &c. To offend in any of these points, is to offend against syntax; and such kind of offence, when gross, is called a solecism, and when more slight, a barbarism. Syntax is generally divided into two parts, viz. concord, wherein the words are to agree in gender, number, case, and person; and regimen or government, wherein one word governs another, and occasions some variations therein. Generally in every language the rules of concord are the same, as being almost every where of the same nature, for the better distinguishing of discourse; thus, from the distinction of two numbers, namely the singular and the plural, the adjective must be made to agree with the substantive accordingly; that is, the former is to be put in this or that number, as the latter is; for the substantive being what is confusedly, though directly, marked by the adjective, should the substantive denote several, there are several subjects of that form signified by the adjective, and consequently this should be in the plural number, as *virī fortes*, &c. Again, as there is a distinction of masculine and feminine in most languages, there hence arises a necessity of putting the substantive and adjective in the same gender; and, in like manner, verbs should agree in number and person with nouns and pronouns: but should any thing, in writing or discourse, be apparently contrary to those rules above-mentioned, this is by some figure or other in grammar, whereby something is implied, or the ideas themselves are considered more than the words that represent them. Regimen, is that part of syntax which regulates the dependency of words, and the alterations which one occasions in another. In general, the regimen, or constitution of government, is almost intirely arbitrary, and varies greatly in all languages. For one language forms its regimen by cases, as the Latin and Greek. Others, instead of cases, make use only of small particles, as the English, *by, of, to*, &c. The French, Spanish, and Italian by *de, a, da*, &c. There are, however, some few maxims which hold good in every language, as, 1. That there is no nominative case in any sentence but has a reference to some verb either expressed or understood. 2. That there is no verb which has not its nominative case expressed or understood, though in the Latin before an infinitive, there is an accusative. 3. That there is no adjective but has a relation to some substantive. 4. That there is no genitive case but is governed by some other noun. This rule does not so apparently hold in the modern, as in the ancient languages, as the particle *of, de*, &c. which are the proper signs of the genitive case, are frequently used as prepositions. 5. That the regimen of verbs is frequently laid upon different kinds of relations, according to custom or usage, which yet does not change the specific relation of each case, but only shews that custom has made choice of this or that according to fancy. Sometimes these different governments have a power of changing the sense according to the different custom of languages, in which case the particular use of languages must be always consulted. There is one very common fault committed in regimen, which should be carefully avoided by accurate writers, viz. the using two verbs that require different cases together, as only governing one case, as in this example, "after embracing and giving his blessing to his son," where, "embracing," requires an accusative case, and "giving," a dative. The same is to be observed in the regimen of nouns.

PROSODY.

Prosody comprises, 1. The accenting of the syllables of a word. 2. The giving of a syllable its proper quantity; and 3. The manner of making verses. The two first parts are, in a great measure, dependent on one another; and in some languages, as the English, they are nearly the same: on these depend the pronunciation of words. The accent of syllables relates chiefly to the stress and tone of voice in pronouncing them; in English, we lay the stress on the long syllable. The proper accenting of words ought to be well understood; since nothing is more harsh and disagreeable to the ear, than to hear a person speak or read with wrong accents: and, indeed, in English, the same word is often both a noun and a verb, distinguished only by the accent, which is on the first syllable of the noun, and on the last verb; as *férment* and *fermént*,

récord and *recórd*, &c. We are to observe also, that in order to a just expression of words, some require only a single accent on the long syllable; as in *tórmént*, &c. but in others it should be marked double, as in *ánímal*, because it is pronounced as if the letter was writ double, viz. *ánnímal*. The rules for the accent or quantity of English words are not easily to be given, being subject to innumerable exceptions. The following we shall give from Dr. Johnson.

1. Of dissyllables formed by affixing a termination, the former syllable is commonly accented, as *childish*, *kingdom*, *áctest*, *ácted*, *tóilsome*, *lóver*, *schóffer*, *fairer*, *fóremost*, *zéalous*, *fúlness*, *gódly*, *méckly*, *ártist*.

2. Dissyllables formed by prefixing a syllable to the radical word, have commonly the accent on the latter; as *to begét*, *to beséem*, *to bestów*.

3. Of dissyllables, which are at once nouns and verbs, the verb has commonly the accent on the latter, and the noun on the former syllable; as, *to descánt*, *a descánt*; *to cemént*, *a cemént*; *to contráct*, *a contráct*.

This rule has many exceptions. Though verbs seldom have their accent on the former, yet nouns often have it on the latter syllable; as *delight*, *perfúme*.

4. All dissyllables ending in *y*, as *cránny*; in *our*, as *labóur*, *fávour*; in *ow*, as *willow*, *wállow*; except *allow*; in *le*, as *báttle*, *bíble*; in *ish*, as *bánish*; in *e*, as *cámbric*, *cássoc*; in *ter*, as *bátter*; in *age*, as *cóurage*; in *en*, as *fásten*; in *et*, as *quíet*, accent the former syllable.

5. Dissyllable nouns in *er*, as *cánker*, *bútter*, have the accent on the former syllable.

6. Dissyllable verbs terminating in a consonant and *e* final, as *comprise*, *escápe*; or having a diphthong in the last syllable, as *appéase*, *revéál*; or ending in two consonants, as *atténd*, have the accent on the latter syllable.

7. Dissyllable nouns having a diphthong in the latter syllable, have commonly their accent on the latter syllable, as *appláuse*; except words in *ain*, as *cértaín*, *mountáin*.

8. Trissyllables formed by adding a termination, or prefixing a syllable, retain the accent of the radical word, as *lovéliness*, *ténderness*, *contémner*, *wágonner*, *physícal*, *bespáttér*, *commenting*, *commendéng*, *assúrance*.

9. Trissyllables ending in *ous*, as *grácíous*, *árduous*; in *al*, as *cápítal*; in *ion*, as *méntion*, accent the first.

10. Trissyllables ending in *ce*, *ent*, and *ate*, accent the first syllable, as *counténance*, *contínence*, *ármament*, *ímminent*, *élegant*, *própagate*, except they be derived from words having the accent on the last, as *comívance*, *acquáintance*; or the middle syllable hath a vowel before two consonants, as *promúlgate*.

11. Trissyllables ending in *y*, as *éntity*, *spécify*, *liberty*, *victory*, *subsidy*, commonly accent the first syllable.

12. Trissyllables in *re* or *le* accent the first syllable, as *légible*, *théâtre*, except *disciple*, and some words which have a position, as *exámple*, *épístle*.

13. Trissyllables in *ude* commonly accent the first syllable, as *plénitude*.

14. Trissyllables ending in *ator*, *atour*, as *créator*, or having in the middle syllable a diphthong, as *endeávour*; or a vowel before two consonants, as *doméstic*, accent the middle syllable.

15. Trissyllables that have their accent on the last syllable are commonly French, as *acquiesce*, *repurtée*, *magazíne*, or words formed by prefixing one or two syllables to an acute syllable, as *immátüre*, *overchárge*.

16. Polysyllables, or words of more than three syllables, follow the accent of the words from which they are derived, as *árrogátíng*, *contínency*, *incóntinently*, *comméndable*, *commúnícableness*. We should, therefore, say, *disputáble*, *indisputáble*, rather than *disputable*, *indisputable*; and *advertísément* rather than *advértisement*.

17. Words in *ion* have the accent upon the antepenult, as *salvátion*, *perturbátion*, *concóction*; words in *atour* or *ator* on the penult, as *dedicátor*.

18. Words ending in *le* commonly have the accent on the first syllable, as *ámicable*, unless the second syllable have a vowel before two consonants, as *combústible*.

19. Words ending in *ous*, have the accent on the antepenult, as *uxúrious*, *volúptuous*.

20, Words ending in *ty* have their accent on the antepenult, as *pustillanimit̃y, activity*.

These rules are not advanced as complete or infallible, but proposed as useful. Almost every rule of every language has its exceptions; and in English, as in other tongues, much must be learned by example and authority. Perhaps more and better rules may be given that have escaped my observation.

Quantity ascertains the time in which a syllable is pronounced, determining it to be long or short. Quantity distinguishes verse from prose; and the economy and arrangement of quantities, that is, the distribution of long and short syllables, makes what we call the metre. The quantities are distinguished, among grammarians, by the characters *u*, short, as *p̃er*; and *-*, long, as *r̃os*. There is also a common, variable, or dubious quantity; that is, syllables that are one time taken for short ones, and at another time for long ones, as the first syllable in *A'tlas, p̃atres, &c.* Feet are made up of quantities. The quantity of a syllable is either natural or accidental: natural quantity is that taken from the nature of the vowel, as *re* in *resisto*, is short, and *de* in *depello* is long. Accidental quantity is that departing from the natural quantity, merely by accident, as *re* in *restiti* is long, because it is immediately followed by two consonants; and *de* in *deamo* is short, because it immediately precedes a vowel. The quantity of syllables is known two ways. 1. By rules for that purpose. And, 2. By authority. The rules for this end are taught by that part of grammar called prosody; the authority made use of in this case is no more than examples from, or the testimony of, approved authors; and is never used but either when the rules are deficient, or when we are unacquainted with them. The quantity of the syllables is but little fixed in the modern tongues; and there is still less regard paid to it in the composition of modern verses. The want of feet, or rather the shortness and uniformity of our feet, makes a great difference between the numbers of the ancient and modern verse.

Versification is the disposing of long and short syllables in a discourse, so that they may run with an agreeable cadence, the like being also reiterated in the course of the piece. This repetition, according to Bossu, is necessary to distinguish the notion of verse from that of prose; for in prose, as well as verse, each period and member are parts of a discourse, consisting of a certain number of long and short syllables; only prose is continually diversifying its measures and cadences, and verse regularly repeating them. This repetition of the poets appears even in the manner of writing; for one verse being finished, they return to the beginning of another line, to write the verse following, and it is to this return, that verse owes its name. Verses are sometimes denominated from the number of feet, whereof they are composed, as the monometer, dimeter, trimeter, tetrameter, pentameter, hexameter, &c. See HEXAMETER, &c. Some also, from the kinds of feet used in them, as the pyrrhichion, proceleusmatic, iambic, trochaic, &c. See PYRRHICHION, &c. Sometimes verses are denominated from the names of the inventors, or the authors who have used them with most success, as the anacreontic, archilochian, asclepiæ, alcaic, sapphic, &c. See ANACREONTIC, &c. The moderns have invented heroic or alexandrine verses; the ancients likewise invented various kinds of poetical devices in verse, as centos, echos, &c. See ALEXANDRINE, &c.

The feet of our verses are either iambic, as *alóft, creáte*; or, trochaic, as *hóly, léfty*.

Our iambic measure comprises verses of four syllables.

With ravish'd ears
The monarch hears.

Of six,

Thus while we are abroad,
Shall we not touch our lyre?
Shall we not sing an ode?
Or shall that holy fire,
In us that strongly glow'd,
In this cold air expire?

Of eight, which is the usual measure of short poems,

And may at last my weary age
Find out the peaceful hermitage,
The hairy gown, and mossy cell
Where I may sit, and nightly spell
Of ev'ry star the sky doth shew,
And ev'ry herb that sips the dew.

Of ten, which is the common measure of heroic and tragic poetry,

The courts are filled with a tumultuous din
Of crowds, or issuing forth, or entering in:
A thorough-fare of news; where some devise
Things never heard, some mingle truth with lies:
The troubled air with empty sounds they beat,
Intent to hear, and eager to repeat.

In all these measures the accents are to be placed on even syllables; and every line considered by itself is more harmonious, as this rule is more strictly observed. The variations necessary to pleasure belong to the art of poetry, not the rules of grammar.

Our trochaic measures are

Of three syllables,

Here we may
Think and pray
Before death
Stops our breath;
Other joys
Are but toys.

Of five,

In the days of old,
Stories plainly told,
Lovers felt annoy.

Of seven,

Fairest piece of welform'd earth,
Urge not thus your haughty birth.

In these measures the accent is to be placed on the odd syllables.

These are the measures which are now in use, and above the rest those of seven, eight, and ten syllables. However, various other kinds of verses have been invented, and used by different poets, as above observed.

The authors who have written on grammar are innumerable. The grammar of the English language by Dr. Louth, and that by Lindley Murray, are deservedly held in high estimation.

GRAMMAR, PHILOSOPHIC, OR UNIVERSAL. "Grammar," says the Rev. Mr. Bruce, "considered as an art, necessarily supposes the previous existence of language; and as its design is to teach any language to those who are ignorant of it, it must be adapted to the genius of that particular language of which it treats. But grammar, considered as a science, views language only as it is significant of thought. Neglecting particular and arbitrary modifications introduced for the sake of beauty or elegance, it examines the analogy and relation between words and ideas; distinguishes between those particulars, which are essential to language, and those which are only accidental; and thus furnishes a certain stand-

ard, by which different languages may be compared, and their several excellencies or defects pointed out. This is what is called Philosophic or Universal Grammar." Encyc. Brit. See LANGUAGE.

GRAMMARIAN, was anciently a title of honour, literature, and erudition, being given to persons accounted learned in any art or faculty. But it is now often used as a term of reproach, to signify a plodding person, employed about words and phrases, but inattentive to the beauties of expression and delicacy of sentiment. The ancient grammarians, called also philologers, must not be confounded with the grammatists, whose business was to teach children the first elements

elements of language. Varro, Cicero, Messala, and even Julius Caesar, thought it no dishonour to be ranked as grammarians, who had many privileges granted to them by the Roman emperors.

GRAMMONT, a town of France, in the department of Upper Vienne, and late province of Limosine, 15 miles N.E. of Limoges.

GRAMMONT, or **GEERSBERGH**, a town of France, in the department of the Scheldt, and late province of Austrian Flanders, 17 miles S. E. of Ghent, and 20 miles W. of Brussels.

GRAMPIAN HILLS, a chain of mountains in Scotland, which run from E. to W. almost the whole breadth of the kingdom.

GRAMPOUND, a town of England, in Cornwall, 46 miles S. W. of Launceston.

GRAN, or **ESZTERGAN**, a large and strong town of Hungary, 55 miles S. E. of Presburg.

GRANADA, a province of Spain, which was long an independent kingdom. It made a part of the ancient Bætica; and was inhabited by the Bastuli, the Sexitani, &c. It is sometimes called Upper Andalusia. It is bounded on the S. and E. by the Mediterranean, on the W. and N. by Lower Andalusia, and on the N. E. by Murcia. Its extent from W. to E. is 210 miles; but its greatest breadth exceeds not 80. The air is temperate and healthy; and though there are many mountains in the province, and some of them very high, yet they are almost every where covered with vines and fruit-trees, together with laurel, myrtle, sweet basil, thyme, lavender, marjoram, and other aromatic herbs; which give an exquisite taste to the flesh of their sheep and cattle. A great deal of silk and sugar, flax and hemp, honey and wax, is also produced here; besides dates and acorns, superior to the finest nuts; good stone for building; several sorts of gems; sumach, used in dressing goat-skins; and galls, of which a dye is made for leather. The valleys, with which the mountains are interspersed, are extremely beautiful and fertile.

GRANADA, the capital of the above province, is 125 miles S. W. of Murcia, and 183 S. of Madrid. Lon. 3. 30. W. Lat. 37. 17. N.

GRANADA, NEW, a province of S. America, in Terra Firma, about 75 miles in length, and as much in breadth. It is bounded on the N. by Carthagena and St. Martha, on the E. by Venezuela, on the S. by Popayan, and on the W. by Darien. It contains mines of gold, copper, and iron; horses, mules, good pastures, corn, and fruits. It belongs to the Spaniards, and Santa Fe de Bagota is the capital.

GRANADE. See **GRENADE**.

GRANADIER. See **GRENADIER**.

GRANADILLOES, or **GRENADINES**, dangerous islands of the Caribbees, in America, having St. Vincent on the N. and Granada on the S.

GRANARD, or **GRENARD**, a borough and post-town of Ireland, in Longford, Leinster; 52 miles from Dublin, and 16 S. of Cavan.

GRANARY, a building in which corn is deposited, especially when designed to be kept for a considerable time. In constructing granaries, the principal objects are, strength or solidity of the edifice, and its exposure to the most drying winds. In the county of Kent, previously to removing the corn to such a magazine, it is tossed with a shovel from one end of a large room to the other; by which means the lighter substances fall into the middle, while the ripe grain only is collected at the sides or extremities of the room. The corn is then screened, and conveyed to the granaries, where it is spread to the depth of half a foot on the floor, and turned twice in the week: the operation of screening is repeated once a week. At the expiration of two months, the corn is heaped up to the thickness of a foot, for a similar period, during which it is turned once, or, if the weather be damp, twice in the week, and is also occasionally screened. At the end of five or six months, the heaps are enlarged to the height of two feet, and turned once or twice in a month, the operation of screening being likewise from time to time continued. When grain has thus lain for one year, the quantity is increased to the thickness of two and a half or three feet; it is turned once in the course of three weeks or a month, and screened accordingly. At the expiration of two or three years, it is moved only once in two months, and screened every quarter; but, in proportion to the length of time it is kept, the turning, &c. should be more frequently repeated, in

consequence of which the grain will be much improved. In storing corn, it is requisite to leave an area of a yard in width on every side of each heap, into which the corn should be tossed as often as appears necessary. In the Kentish granaries, two square holes are made at each end of the floor, and a circular one in the middle of the building, through which the corn is shifted from the upper rooms into those below, and again from the lower rooms into the upper ones, in order that it may be the more effectually turned and aired. The screens or frames employed for sifting the corn are made with two partitions, for the purpose of separating the pure grain from the dust, which falls into a bag. By these precautions, corn has often been preserved sound and pure for thirty years; and it is a circumstance worthy of notice that, though by long keeping the grain decreases in bulk, yet it will yield proportionably more flour, and the bread will likewise be whiter and more wholesome; as the superfluous moisture only evaporates during the frequent airing. M. Du Hamel, and Dr. Hales, have recommended various contrivances for ventilating, or introducing fresh air through corn deposited in granaries, with a view to preserve it sweet and dry, as well as to secure it from weevils or other insects. This object is to be effected, by constructing granaries with lattice-work, and hair-cloth at the bottom. The ventilators for supplying fresh air may be affixed to the wall, either within or on the outside of the granary, beneath the floor, or in the ceiling; but, in the former case, it will be necessary to place the handle of the lever externally, as otherwise the person working the machinery would be exposed to suffocation, when the corn is fumigated with sulphur for the expulsion of weevils. Small moveable ventilators may be constructed on this plan, for ventilating corn in large bins deposited in granaries. Similar contrivances may be applied to the lowest floors of small magazines, so as to be worked by men standing on the ground, either within or without the buildings. In the eighth volume of the "Letters and Papers of the Bath and West of England Society," &c. Thomas South, Esq. gives a description of a cheap and efficacious ventilator, for preserving corn on ship-board. This machine consists of a forcing-pump, with perforated tubes annexed to it; and by means of which fresh air may be communicated to every part of the cargo. Mr. South's air-vessel is, for the sake of cheapness, confined to a diameter of ten inches; but he observes, that, if the latter be enlarged to fourteen inches, the effect of the machine will be nearly doubled; and if the length of the trough (by the suction-valve) be extended ten inches, a power will be obtained capable of ventilating a cargo of 400 tons in the course of one hour. To preserve corn in barns or granaries, Dr. Darwin observes, it is requisite first to make them dry, and, secondly, to keep them in that state; because no seeds will vegetate without moisture. In order to dry seeds, the heaps should be frequently turned over in warm dry weather; hence, in this climate, the doors and windows of granaries should open towards the south, for the reception of the warmth of the sun, with air-holes round the building, for sufficient ventilation; and which apertures ought to be sheltered from rain or snow, by boards placed for that purpose on the outside.—Heaps of corn should be surrounded with planks, in order to prevent them from touching either brick or stone walls; because, when cold north-east winds are succeeded by moist and warm south-west winds, such walls frequently precipitate the moisture from the atmosphere, and communicate it to those bodies which are in contact with them. According to Mr. Tull, the safest method of preserving a large quantity of wheat is, to dry it gradually in a malt-kiln on an air-cloth, with no other fuel than clean straw, and with a heat scarcely exceeding that produced by the rays of the sun. In this temperature, the grain is to remain from four to twelve hours, in proportion to its previous dampness. The vegetative principle of the corn is not destroyed by this process; as instances have occurred of its growing when sown, after it had been thus treated and kept for seven years. The preservation of grain from the ravages of insects may be effected by timely and frequent screening, and ventilation; as little or no inconvenience will follow corn or malt lodged dry, but what evidently results from a neglect of these precautions. For, whether the obvious damage arise from the weevil, the moth, or the beetle, that damage has ceased at the time the vermin make their appearance under either of these species, they being, when in this last state of existence, only propagators of their respective kinds of vermiculi;

culi; which, while they continue in that form do the mischief. In this last, or insect-state, they eat little, their principal business being to deposit their eggs, which unerring instinct prompts them to do where large collections of grain furnish food for their successors while in a vermicular state. It is therefore the business of industry to prevent future generations of these ravagers, by destroying the eggs previous to their hatching; and this is best accomplished by frequent screening, and exposure to draughts of wind or fresh air. By frequently stirring the grain, the cohesion of their eggs is broken, and the nidus of those minute worms is destroyed, which on hatching collect together, and weave numerous nests of a cobweb-like substance for their security. To these nests they attach, by an infinity of small threads, many grains of corn together, first for their protection, and then for their food. When their habitations are broken and separated by the screen, they fall through its small interstices, and may be easily removed from the granary with the dust. Those that escape an early screening will be destroyed by subsequent ones, while the grain is but little injured; and the corn will acquire thereby a superior purity. But by inattention to this, and sometimes by receiving grain already infected into the granary, these vermin, particularly the weevil, will soon spread themselves in that state every where upon the surface, and darken the walls by their number. Under such circumstances hens, with new hatched chickens, if turned on the heap, will traverse, without feeding (or very sparingly so) on the corn, wherever they spread; as they seem insatiable in the pursuit of these insects. When the numbers are reduced within reach, a hen will fly up against the walls, and brush them down with her wings, while her chickens seize them with the greatest avidity. This being repeated as often as they want food, the whole species will in a day or two be destroyed. Of the phalana, or moth, and the small beetle, they seem equally voracious: on which account they may be deemed the most-useful instruments in nature for eradicating these noxious and destructive vermin.

GRANATITE, Cross-Stone, a mineral found in Spain, France, and Switzerland. It is crystallized in a very peculiar form; two six-sided prisms intersect each other at right angles, or obliquely. Hence its name, cross-stone. It is of a reddish brown colour: specific gravity 3.3, nearly; fusible before the blow-pipe: its component parts are,

Silica	33
Alumina	44
Lime	3.84
Oxide of iron	13
Oxide of manganese	1
Matter lost	5.16

100

GRAND ASSIZE. See **ASSIZE**.

GRAND DISTRESS, [*districtio magna*, Lat.] in English law, a writ of distress, so called on account of its extent, which reaches to all the goods and chattels of the party within the county. This writ lies in two cases: either when the tenant or defendant is attached and appears not, but makes default; or where the tenant or defendant hath once appeared, and after makes default. On such occasions, this writ lies by common law, in lieu of a petit cape.

GRAND GUSTO, among painters, a term used to express that there is something in the picture very great and extraordinary, calculated to surprise, please, and instruct.

GRAND JURY, GRAND LARCENY, &c. See **JURY, LARCENY, &c.**

GRAND LAKE, a lake of North America, in New Brunswick, near St. John's river, 30 miles long, from 8 to 10 broad, and in some places 40 fathoms deep.

GRAND RIVER, or **RIO GRANDE**, a river in Africa, which runs into the Atlantic, in Lon. 13. 50. W. Lat. 11. 0. N.

GRAND RIVER, a river of North America, which runs N. W. into Lake Erie, 80 miles S. W. of Presque Isle.

GRANDE, two rivers of South America; 1. in Peru, near Cayanta, whose sands are rich in gold; 2. in Brasil.

GRANDEE, in Spain, is used absolutely to denote the prime

lords of the court, to whom the king has once given leave to be covered in his presence: there are some grantees for life only; made by the king's saying simply, Be covered. Others are grantees by descent; made by the king's saying, Be covered for thyself and heirs. These last are reputed far above the former. Some have three or four grandeeships in their family.

GRANDEUR. See **SUBLIMITY**.

GRANDS SEAUX, or GREAT SEALS, a nation of North American Indians, who inhabit the country S. of the Missouri. They have about 300 warriors.

GRANDVILLE, a town of France in the department of the Channel, and late province of Normandy, 15 miles S. by E. of Coutances.

GRANITE, a genus of stones of the order petre, belonging to the class saxa. The principal constituent parts of this stone are felt-spar or rhombic quartz, mica, and quartz. These ingredients constitute the hardest sort of granite, and that most anciently known. That into which schoerl enters is more subject to decomposition. They never have any particular texture or regular form, but consist of enormous shapeless masses extremely hard. In the finer granites the quartz is transparent; in others generally white or grey, violet or brown. The felt-spar is generally the most copious ingredient, and of a white, yellow, red, black, or brown colour. The mica is also grey, brown, yellow, green, red, violet, or black; and commonly the least copious. The schoerl is generally black, and abounds in the granites that contain it. Hence the colour of the granites depends principally on that of the spar or schoerl. The red granites consist commonly of white quartz, red felt-spar, and grey mica; the grey ones of white quartz, grey or violet felt-spar, and black mica. The black granites commonly contain schoerl instead of felt-spar; and the green usually contain green quartz. On exposing granite to the flame of the blow-pipe, the component ingredients separate from one another. Mr. Gerhardt, having melted some in a crucible, found the felt-spar run into a transparent glass; below it the mica lay in form of black flag, the quartz remaining unaltered. It melted somewhat better when all the three were powdered and mixed together; though even then the quartz was still discernible by a magnifying glass. Hence we may explain the reason why grains of a white colour are sometimes found in volcanic lavas. The mixture of mica prevents the siliceous or quartz from splitting or cracking; and hence its infusibility and use in furnace-building. Granites are seldom slaty or laminated. In those of a close texture, the quartz and schoerl predominate. They take a good polish; for which reason the Egyptians formerly, and the Italians still, work them into large pieces of ornamental architecture, for which they are extremely fit, as not being liable to decay in the air.

GRANSON, a town of the Helvetic republic, in Neuchâtel, 16 miles S. W. of Neuchâtel.

GRANT, in law, a conveyance in writing of such things as cannot pass or be conveyed by word only; such are rents, reversions, services, advowsons in gross, tithes, &c. The person making such a conveyance is called the grantor, and he to whom the grant is made, the grantee.

GRANTHAM, a town of Lincolnshire, 30 miles S. of Lincoln, and 110 N. of London.

GRANVILLE, a fertile county of North Carolina, in Hills-bury district, bounded on the N. by Virginia.

GRANULATION, in chemistry, is an operation by which metallic substances are reduced into small roundish particles, to facilitate their combination with other substances. This operation consists only in pouring the melted metal slowly into a vessel filled with water, which is in the mean time to be agitated with a broom. With melted copper, however, which is apt to explode with great violence on the contact of water, some precautions are to be observed. In the brass-works at Bristol, copper is granulated, without danger of explosion, by letting it fall in small drops into a large cistern of cold water covered with a brass-plate. In the middle of the plate is an aperture; in which is secured with Sturbridge clay a small vessel, whose capacity does not exceed a spoonful, perforated with many minute holes through which the copper passes. A stream of cold water passes through the cistern. If allowed to grow hot the copper will fall to the bottom and run into flat plates instead of granulating. Lead or tin may be granulated by pouring them when melted into a box; the internal surface

face of which is rubbed with powdered chalk, and the box strongly shaken till the grains have become solid.

GRAPE HYACINTH. See **HYACINTHUS**.

GRAPEs, in the manege, a term used to signify the arrests or mangy tumours that happen in the horse's legs.

GRAPE-SHOT, in artillery, is a combination of small shot, put into a thick canvas-bag, and corded strongly together, so as to form a kind of cylinder, whose diameter is equal to that of the ball adapted to the cannon. The number of shot in a grape varies according to the service or size of the guns: in the sea-service nine is always the number; but by land it is increased to any number or size, from an ounce and a quarter in weight to three or four pounds. In sea-service the bottoms and pins are made of iron, whereas those used by land are of wood.

GRAPHITES, in mineralogy, a mineral consisting principally of carbon with a little iron, and generally a little silica or alumina; when pure it burns with a reddish flame, emitting beautiful sparks, and a smell of sulphur, and leaving a little residuum. Its colour is dark iron-grey, or brownish black; when cut, blueish grey. Opaque: structure slaty. Texture fine-grained. Brittle. Specific gravity about 2. Feels somewhat greasy, stains the fingers, and marks strongly. In modern chemistry it is denominated carburet of iron; and one of the species is plumbago; the use of which, when manufactured into pencils, is known to every one. When pure it consists of,

90 carbon

10 iron

100

GRAPHOMETER, a mathematical instrument, otherwise called a semicircle; the use of which is to observe any angle whose vertex is at the centre of the instrument in any plane (though it is most commonly horizontal, or nearly so,) and to find how many degrees it contains. The graphometer is a graduated semicircle, ACB, (Plate LXXVIII. fig. 9 and 10,) made of wood, brass, or the like, and so fixed on a fulcrum, GH, by means of a brass-ball and socket, that it easily turns about, and retains any situation. It has two sights fixed on its diameter, AC, and at the centre there is commonly a magnetical needle and compass in a box. There is likewise a moveable ruler or index, ED, with two sights, P, P, which turns round the centre, and retains any situation given it. To measure by this instrument an angle, ACB, in any plane, and comprehended between the right lines AC and BC, drawn from two points, A and B, to the place of station, C, (fig. 11.) Let the graphometer be placed at C, supported by its fulcrum; and let the immovable sights on the diameter of the instrument, DE, be directed towards the point, A; and likewise while the instrument remains immovable, let the sights of the ruler, FG, which is moveable about the centre, C, be directed to the point, B. Now it is evident, that the moveable ruler cuts off an arch, DG, which is the measure of the angle, ACB, sought. Moreover, by the same method, the inclination of DE, or of FG, may be observed with the meridian-line, which is pointed out by the magnetic needle inclosed in the box, and moveable about the centre of the instrument.

GRAPNELS, a sort of anchor with four flukes, serving for boats to ride by. There is also a kind called fire and chain-grapnels, made with four-barbed claws, instead of flukes; and used to catch hold of the enemy's rigging, or any other part, in order for boarding them. A fire-grapnel, in some respects, resembles the former, but differing in the construction of its flukes, which are furnished with strong barbs on its points. These machines are usually fixed on the yard-arms of a ship, to grapple any adversary whom she intends to board.

GRASHOPPER, or more properly **GRASSHOPPER**, in entomology. See **GRYLUS**.

GRASON, an island in the gulf of Bothnia, near the coast of Sweden, 15 miles long, and 2 broad. Lon. 18. 20. E. Lat. 60. 22. N.

GRASS, in botany, is defined to be a plant having simple leaves, a stem generally jointed and tubular, a husky calyx, called Gluma, and the seed single. Hence wheat, oats, barley, &c. are properly grasses, while clover and some other similar plants are not grasses, though so frequently called by that name. Of grass

the leaves are food for cattle, the small seeds for birds, and the larger grain chiefly for man. And it is observable, that nature has so provided, that cattle (in grazing) seldom eat the flower intended to produce seed, unless compelled by hunger. For the culture of the principal sorts of grasses, see **HUSBANDRY**.

GRASSE, a town of France, in the department of Var, and late province of Provence. Lon. 6. 56. E. Lat. 43. 39. N.

GRATINGS, in a ship, are small edges of sawed plank, framed one into another like a lattice or prison grate, lying on the upper deck, between the main-mast and fore-mast, serving for a defence in a close fight, and also for the coolness, light, and convenience, of the ship's company.

GRATIOLA, **HEDGE-HYSSOP**; a genus of the monogynia order, and diandria class of plants; natural order, Personatæ. Corolla irregular; stamina, two, barren; capsule bilocular; calyx seven-leaved, with the two exterior ones patulous. It has twelve species.

GRATIOSA, or **GRACIOSA**, one of the Canary islands. Also one of the Azores.

GRATITUDE, in ethics, is a virtue disposing the mind to an inward sense and outward acknowledgement of benefits received. Examples of ingratitude, Mr. Paley observes, check and discourage voluntary beneficence; hence the cultivation of a grateful temper is a consideration of public importance. A second reason for cultivating in ourselves that temper is: that the same principle which is touched with the kindness of a human benefactor, is capable of being affected by the divine goodness, and of becoming, under the influence of that affection, a source of the purest and most exalted virtue. The love of God is the sublimest gratitude. It is a mistake, therefore, to imagine, that this virtue is omitted in the Scriptures; for every precept, which commands us "to love God, because he first loved us," pre-supposes the principle of gratitude, and directs it to its proper object.

GRATZ, or **GRAZ**, a handsome town of Germany, capital of Stiria. Lon. 15. 26. E. Lat. 47. 4. N.

GRATZ, a town of Silesia, four miles S. of Trappau.

GRAUDENTZ, or **GRUDFIANDS**, a town of the late Polish Prussia, and present duchy of Warsaw, in the palatinate of Culm, thirty miles N. of Thorn.

GRAVE, [*gravis*,] in grammar, a species of accent opposite to acute. The grave accent is expressed thus ('); and shews, that the voice is to be depressed, and the syllable over which it is placed pronounced in a low deep tone.

GRAVE, in music, is applied to a sound which is in a low or deep tone. The thicker the chord or string, the more grave the tone or note, and the smaller the acuter. Notes are supposed to be the more grave, in proportion as the vibrations of the chord are less quick.

GRAVE, in the Italian music, serves to denote the slowest movement.

GRAVE, in geography, a city of Batavia, in the department of the Dommel and Scheldt, and late province of Dutch Brabant, eight miles S. of Nimeguen.

GRAVEL, in medicine, is a disorder affecting chiefly the bladder and ureters; it is occasioned by a sandy or gritty substance which collects in those parts, produces considerable pain, and at length obstructs the due secretion and excretion of the urine.

GRAVEL, in agriculture and gardening, is a congeries of pebbles; which, if mixed with stiff loam, make excellent and durable gravel-walks. For this purpose, the bottom should be laid with lime-rubbish, large flints, or any other hard substance, to the depth of six or eight inches, in order to prevent any weeds from shooting through the surface. Over this stratum, the gravel is to be strewed six or eight inches thick, and somewhat sloping, that all the larger stones may roll off to the sides. The next operation is that of raking, when the large stones are to be removed, and the walks carefully rolled in every direction, especially during or after hard showers: thus they will bind, and become very firm. The most proper gravel for walks, is that which abounds with smooth round pebbles; for these, when mixed with a small portion of loam, are not so liable to be turned up by the feet in walking, as those of a rough and irregular shape.

GRAVELLY LANDS, or **SOILS**, are such as abound with gravel or sand, which easily admit both heat and moisture. They receive but little benefit from the latter, if there be a loose bed at the bot-

tom, because it easily evaporates; but, if the stratum be firm, for instance, clay or stone, the moisture is too long retained, so as to chill the soil and render it unfruitful. The best method of counteracting this inconvenience, is to manure such land with chalk, which is slightly to be ploughed in, that it may not sink too deep into the ground.

GRAVELINES, a very strong town of France, in the department of the North, and late French Flanders, twelve miles E. of Calais. Latitude $50^{\circ} 59' 10''$ N. Longitude from Greenwich $2^{\circ} 7' 35''$ E. It is high water here at the time of the full and change of the moon precisely at noonday.

GRAVENAC, a county of Suabia.

GRAVENAC, the capital of the county, thirty miles W. of Ulm. Lon. 9. 28. E. Lat. 48. 22. N.

GRAVER. See **ENGRAVING**.

GRAVESANDE, **WILLIAM JAMES**, LL. D. and F. R. S. an eminent mathematician, born of an ancient family at Delft in Holland, in 1688. He studied the civil law at Leyden, but mathematical learning was his favourite amusement. When he had taken his degree in 1707, he settled at the Hague, and practised at the bar, in which situation he cultivated an acquaintance with learned men; with a society of whom, he published a periodical review, intitled *Le Journal Littéraire*, which was continued without interruption from 1713 to 1742, when he died. The most considerable of his works are, 1. A Treatise on Perspective: 2. An Introduction to the Newtonian Philosophy, or a Treatise on the Elements of Physics, Confirmed by Experiments: 3. A Treatise on the Elements of Algebra, for the Use of Young Students: and, 4. A Course of Logic and Metaphysics. The ministers of the republic consulted him on many occasions, and his skill in calculation was often of service to them; as well as his address in decyphering the secret correspondence of their enemies. In 1715, he was sent by the States to congratulate king George I. on his accession: and on his return was appointed professor of mathematics and astronomy at Leyden, where he was the first that taught the Newtonian philosophy. He was intimately acquainted with Sir Isaac Newton, as well as with his doctrine.

GRAVESEND, a town of England, in Kent, situated on the banks of the Thames, twenty-three miles from London.

GRAVIMETER, [from *gravis*, weighty, and *metron*, to measure,] an instrument of glass constructed by Citizen Guyton Morveau, for measuring specific gravities: he adopts this name rather than either areometer or hydrometer, because these latter terms are grounded upon the supposition that a fluid is always the thing weighed; whereas, with regard to solids, the liquid is the known term of comparison to which the unknown weight is referred. See **HYDROMETER**, and **HYDROSTATICS**.

GRAVINA, a town of Naples, in the province of Bari. Lon. 17. 0. E. Lat. 41. 0. N.

GRAVITATION, in physiology, a species of attraction, or the tendency of one body towards another, in consequence of a certain power or principle that is found to affect all bodies, but of which the true nature has not yet been discovered. See **PHYSICS**.

GRAVITY, signifies either the force by which bodies are pressed towards the surface of the earth, or the manifest effect of that force; in which last sense the word has the same signification with weight or heaviness. Concerning gravity in the first sense of the word, or that active power by which all bodies are impelled towards the earth, there have been great disputes. Many eminent philosophers, and among the rest Sir Isaac Newton himself, have considered it as the first of all second causes; an incorporeal or spiritual substance; which never can be perceived any other way than by its effects: an universal property of matter, &c. Others have attempted to explain the phenomena of gravitation by the action of a very subtle ethereal fluid. Sir Isaac Newton observes, that bodies immersed in fluids have two kinds of gravity, the one absolute, and the other relative. Absolute gravity is the whole force wherewith a body tends downwards. Relative gravity is the excess of gravity whereby a body tends downwards more than the fluid which surrounds it. See **PHYSICS**, **PNEUMATICS**, and **HYDROSTATICS**.

GRAVITY, SPECIFIC, denotes the weight belonging to an equal bulk of every different substance. Thus the exact weight of a cubic inch of gold, compared with a cubic inch of water, tin, lead, &c. is called its specific gravity. See **HYDROSTATICS**, and **SPECIFIC GRAVITY**.

GRAY, or **GREY**, a mixed colour, partaking of black and white. In the manege they make several sorts of grays; as the branded or blackened gray, which has spots quite black dispersed here and there. The dappled gray, which has spots of a darker colour than the rest of the body. The light or silver gray, wherein there is but a small mixture of black hairs. The sad or iron gray, which has but a small mixture of white. And the brownish or sandy-coloured gray, where there are bay-coloured hairs mixed with the black.

GRAY, THOMAS, an admired English poet, was the youngest and only surviving son of a reputable citizen of London, and was born in Cornhill in 1716. He was educated at Eton, where he contracted a friendship with Mr. Horace Walpole, and with Mr. Richard West, son of the Lord Chancellor of Ireland. Mr. West and Mr. Gray were both intended for the bar; but the latter was diverted from that pursuit by an invitation to accompany Mr. Walpole in his travels; which he accepted without any determined plan for his future life. During his travels, he wrote a variety of letters to Mr. West and to his parents, which are printed with his poems; and when he returned, finding himself in narrow circumstances, yet with a mind not disposed for active employment, he retired to Cambridge, and devoted himself to study. Soon after his return, his friend West died; and the melancholy impressed on him by this event may be traced in his admired elegy written in a country church-yard, which is thought to have been begun at this time. The first impulse of his sorrow for the death of his friend gave birth to a very tender sonnet in English, on the model of Petrarch; and also to a sublime apostrophe in hexameters, written in genuine classical majesty, with which he intended to begin one of his books *De Principiis Cogitandi*. From the winter of 1742, to his death, his principal residence was at Cambridge, where, in 1763, he became professor of modern history. He died of the gout in 1771, and was buried with his family at Stoke Poges, in Buckinghamshire. The odes of Gray possess uncommon merit, and his Elegy in a Country Church-yard has obtained almost an unexampled run. His letters are instructive and entertaining.

GRAYS, or **GRAYS-THURROCK**, a town of England in Essex, twenty-four miles E. of London.

GREAT BEAR LAKE, a water in the N. W. part of North America, which runs W. into M'Kenzie's River, near the Arctic circle. Its mouth is 250 yards wide.

GREAT BRITAIN. See **BRITAIN**, **ENGLAND**, and **SCOTLAND**.

GREAVES, JOHN, an eminent physician and antiquary, the eldest son of John Greaves rector of Colemore, near Alresford in Hampshire. He was born in 1602, and educated at Balliol College in Oxford, from which he removed to Merton. He was afterwards chosen professor of geometry in Gresham College, and was soon afterwards sent by archbishop Laud to the east, where he made a large collection of oriental MSS. coins, and medals. He also took a careful survey and measurement of the Egyptian pyramids, and made many astronomical observations. After his return in 1640 he was chosen Savilian professor of astronomy at Oxford, but was obliged to resign the professorship by the persecution of the parliamentary visitors. He died in 1652. He wrote *Pyramidographia*, or a Description of the Pyramids in Egypt; *A Discourse on the Roman Foot and Denarius*; and other valuable works.

GREECE, in many respects, one of the most deservedly celebrated countries in the world, was anciently bounded on the N. by Macedonia and the river Strymon; on the W. by the Ionian sea; on the S. by the Mediterranean; on the E. by the Egean Sea and the Archipelago. It extended from the Strymon, by which it was parted from Thrace, to the promontory of Tenarus, the southmost point of the Peloponnesus, now the Morea, about $6^{\circ} 20'$ of latitude, or nearly 440 English miles, and in breadth from E. to W. about 359 miles. The general names by which the inhabitants of this country were known to the ancients were those of Graioi, or Graicoi, from whence the name of Greece is plainly derived. These names are thought to come from Græcus, the father, or (according to some) the son, of Thessalus, who gave name to Thessaly; but some modern critics derive it from *Raga*, the same with *Reu*, the son of Peleg, by the transposition of a letter to soften the sound. These names were afterwards changed for Achæi, or Achivi, and Hellenes, the first, as is supposed, from *Achæus*, the son of Xuthus, the son of Hellen, and father of Ion;

or,

or, according to the fable, the son of Jupiter: the other from Helen, above-mentioned, the son of Deucalion, and father of Dorus, from whom came the Doreans, afterwards a famous nation among the Greeks. Another name by which the Greeks were known in some parts of the country, was that of Pelasgi, which the Arcadians, the most ancient people in Greece, deduced from their pretended founder Pelasgus; who is said to have got such footing in Peloponnesus, that the whole peninsula from him was called Pelasgia. But the most ancient name of all is universally allowed to have been that of Iones, which the Greeks themselves derived from Ion the son of Xuthus; or, as the fable hath it, of Apollo, by Creusa the daughter of Erechtheus the grandson of Deucalion. Josephus, however, affirms, that their original is of much older date; and that Javan, the son of Japhet, and grandson of Noah, was the first who peopled these countries; which Bochart has also rendered very probable. It is true, indeed, that among the Greeks themselves, only the Athenians, and such colonies as sprung from them, were called Iones; but it is also plain, beyond exception, that other nations gave this name to all the inhabitants of Greece.

GREECE, MODERN, now called **EUROPEAN TURKEY**, and by the Turks **RUMELIA**, comprehends Macedonia; Albania, now called **Arnaut**; Epirus, Thessaly, now **Jana**; Achaia, now **Livadia**; the Peloponnesus, now **Morea**; together with the islands on its coasts, and in the Archipelago. The air is extremely temperate and healthy: and the soil fruitful, though badly cultivated; yielding corn, wine, delicious fruits, and abounding with cattle, fowls, and venison.

GREEK CHURCH, is that part of the Christian church which is established in Greece; extending likewise to some other parts of Turkey. It is so called, in contradistinction from the Latin or Romish church; also the Eastern Church, in distinction from the Western. The Romanists call the Greek church the Greek Schism; because the Greeks do not allow the authority of the pope, but depend wholly, as to matters of religion, on their own patriarchs. They have treated them as schismatics ever since the revolt, as they call it, of the patriarch Photius.

GREEK LANGUAGE, as preserved in the writings of the celebrated authors of antiquity, Homer, Hesiod, Demosthenes, Aristotle, Plato, Xenophon, &c. has a great variety of terms and expressions, suitable to the genius and occasions of a polite and learned people, who had a taste for arts and sciences. In it, proper names are significant; which is the reason that the modern languages borrow so many terms from it. When any new invention, instrument, machine, or the like, is discovered, recourse is generally had to the Greek for a name to it; the facility wherewith words are there compounded, affording such as will be expressive of its use; such are, barometer, hygrometer, microscope, telescope, &c. But of all sciences, medicine most abounds with such terms; as diaphoretic, diagnosis, diarrhoea, hæmorrhage, hydrophobia, phthisis, atrophy, &c.

GREEK ORDERS, in architecture, are the Doric, Ionic, and Corinthian; in contradistinction to the two Latin orders, the Tuscan and Composite. See **ARCHITECTURE**.

GREEN, is one of the original prismatic colours, exhibited by the refraction of the rays of light. See **COLOUR**, and **OPTICS**. The green colour of plants has been shewn, by the French chemists, to depend upon the absorption of carbonic acid, and it is supposed that the leaves of plants have the power of decomposing the carbonic acid and water also; the oxygen they emit, while the carbon and hydrogen enter into the composition of the inflammable parts of the plant.

GREEN, among painters and dyers. See **COLOUR-MAKING** and **DYING**.

GREEN BRIAR, a fertile and extensive county of Virginia, surrounded by those of Bath, Randolph, Harrison, Kanhaway, Botetourt, and Montgomery.

GREENCASTLE, a flourishing town of Pennsylvania, in Franklin county.

GREEN-CLOTH, a board or court of justice, held in the computing-house of the king's household, composed of the lord steward, and officers under him, who sit daily. To this court is committed the charge and oversight of the king's household in matters of justice and government, with a power to correct all offenders, and to maintain the peace of the verge, or jurisdiction of the court royal; which is every way about two hundred yards

from the last gate of the palace where his majesty resides. It takes its name, board of green cloth, from a green cloth spread over the board where they sit. Without a warrant first obtained from this court, none of the king's servants can be arrested for debt.

GREEN-FINCH, in ornithology. See **FRINGILLA**.

GREENHOUSE, or **CONSERVATORY**, a house in a garden, contrived for sheltering and preserving the most curious and tender exotic plants, which in our climate will not bear to be exposed to the open air, especially during the winter-season. These are generally large and beautiful structures, equally ornamental and useful. Their length must be proportioned to the number of plants intended to be preserved in them, and cannot therefore be reduced to rule: but their depth should never be greater than their height in the clear; which, in small or middling houses, may be sixteen or eighteen feet, but in large ones from twenty to twenty-four feet; and the length of the windows should reach from about one foot and a half above the pavement, and within the same distance of the ceiling, which will admit of a cornice round the building over the heads of the windows.

GREENLAND, a general name given to the most easterly parts of America, stretching towards the north pole, and comprehending some islands to the north of Europe, lying in very high latitudes. This country is divided into West and East Greenland.

i. **GREENLAND, EAST**, was long considered as a part of the continent of West Greenland, but is now discovered to be an assemblage of islands lying between $76^{\circ} 46'$ and $80^{\circ} 30'$ lat. N. and between 9° and 20° lon. E. It was discovered by sir Hugh Willoughby in 1553, who called it Groenland; supposing it to be a part of the western continent. In 1595, it was again visited by William Barentz and John Cornelius, two Dutchmen, who pretended to be the original discoverers, and called the country Spitzbergen, or Sharp Mountains, from the many sharp-pointed and rocky mountains with which it abounds. They alleged that the coast discovered by sir Hugh Willoughby was some other country; which according to the Hollanders was delineated on their maps and charts by the name of Willoughby land; whereas, in fact, no such land ever existed; and long before the voyage of these Dutchmen, Stephen Barrows, an English shipmaster, had coasted along a desolate country from lat. 78° to $80^{\circ} 11'$ N. which was undoubtedly Spitzbergen. The sea in the neighbourhood of the islands of Spitzbergen abounds very much with whales. It is the common resort of the whale-fishing ships from different countries, and the country itself is frequently visited by these ships; but till the late voyage of captain Phipps, by order of his Majesty, the situation of it was erroneously laid down. It was imagined that the land stretched to the northward as far as 82° N. lat. but captain Phipps found the most northerly point of land, called Seven Islands, not to exceed $81^{\circ} 30'$. Towards the east he saw other lands at a distance, so that Spitzbergen plainly appeared to be surrounded by water on that side, and not joined to the continent of Asia, as former navigators had supposed. He also explored the north and west coasts, but was prevented by the ice from sailing so far north as he wished. The coast appeared neither habitable nor accessible. It is formed of high, barren, black rocks, without the least marks of vegetation; in many places bare and pointed; in others covered with snow appearing even above the clouds. The valleys between the high cliffs were filled with snow and ice. "This prospect," says captain Phipps, "would have suggested the idea of perpetual winter, had not the mildness of the weather, the smooth water, bright sun-shine, and constant day-light, given a cheerfulness and novelty to the whole of this romantic scene." The current ran along this coast half a knot an hour north. The height of one mountain seen here was found by geometrical mensuration to be the $1503\frac{1}{2}$, or $1503\frac{3}{5}$ feet. By a barometer constructed after De Luc's method, the height was found to be $1588\frac{1}{2}$ feet. On this occasion captain Phipps remarks, "I cannot account for the great difference between the geometrical measure and the barometrical according to M. de Luc's calculation, which amounts to $84\cdot7$ feet. I have no reason to doubt the accuracy of Dr. Irving's observations, which were made with great care. As to the geometrical measure, the agreement of so many triangles, each of which must have discovered even the smallest error, is the most satisfactory proof of its correctness. Since my return I have tried both the theodolite and barometer, to discover whether

whether there was any fault in either; and find them, upon trial, as I had always done before, very accurate."

ii. **GREENLAND, WEST**, is now determined by our latest maps to be a part of the continent of America. That part of it which the Europeans have any knowledge of is bounded on the west by Baffin's Bay, on the south by Davis's Straits, and on the east by the northern part of the Atlantic Ocean. It is very mountainous, and some parts of it are so high, that they can be discerned thirty leagues off from sea. The inland mountains, hills, and rocks, are covered with perpetual snow; but the low lands on the sea-side are clothed with verdure in summer. The coast abounds with inlets, bays, and large rivers, and is surrounded with a vast number of islands of different dimensions. Greenland is thought to contain many mines of metal, though none of them are wrought. To the southward of the Danish colony are some appearances of a mine of copper. This country produces rock-crystals both red and white, and whole mountains of the asbestos, or incombustible flax. Around the colony, which is called Good Hope, they find a kind of bastard marble of various colours, which the natives form into bowls, lamps, pots, &c. The animals which abound most in Greenland are, rein-deer, foxes, hares, dogs, and white bears. The hares are white, and very fat; the foxes are white, greyish, and blueish; and smaller than those of Denmark and Norway. The natives keep a great number of dogs, which are large, white, or speckled, and rough, with upright ears. They are timorous and stupid; and neither bay nor bark, but sometimes howl dismally. The natives yoke them in sledges; which, though heavy laden, they will draw on the ice at the rate of seventy miles in a short winter's day. These poor animals are very ill rewarded for their service; being left to provide for themselves, except when their masters happen to catch a great number of seals, when they are regaled with the blood and entrails. Greenland is frequented by great numbers of ravens, eagles of a prodigious size, falcons, and other birds of prey; besides a kind of linnets, which warble very melodiously. Whales, sword-fish, porpoises, sea-cows, sea-wolves, &c. abound on the coasts; also holybuts, turbot, cod, haddock, &c.

GREENOCK, a sea-port town of Scotland, in Renfrewshire, and one of the ports of Glasgow, 22 miles W. of that city.

GREENSBOROUGH, a post-town of Georgia, 30 miles from Lexington, and 71 W. by S. of Augusta.

GREENSBURG, a post-town of Pennsylvania, capital of Westmoreland county, 31 miles S.E. by E. of Pittsburg.

GREENSICKNESS. See **MEDICINE**.

GREENSVILLE, a county of Virginia, bounded on the west, north, and east, by Brunswick, Southampton, and Sussex counties.

GREENVILLE, a county of South Carolina, in Washington district, bounded on the east and south by Spartanburg and Pendleton counties.

GREENVILLE, or **GREENSVILLE**, a town of South Carolina, in Darlington county, 135 miles N. by E. of Charlestown.

GREENVILLE, a post-town of North Carolina, 23 miles from Washington.

GREEN WAX, is used where estates are delivered to the sheriffs out of the exchequer, under the seal of that court, made in green wax, to be levied in the several counties. It is mentioned in the 43d stat. Ed. III. c. 9, and 7 Hen. IV. c. 4.

GREENWICH, a town of England in Kent, pleasantly situated on the banks of the Thames, 5 miles E. of London. It had formerly a royal palace, built by Humphry, duke of Gloucester, enlarged by Henry VII. and completed by Henry VIII. The latter often chose this town for his place of residence; as did also queen Mary and Elizabeth, who were born in it. D. Humphrey began a tower on the top of the steep hill in the park, which was finished by Henry VII. but afterwards demolished, and a royal observatory erected in its place by Charles II. furnished with mathematical instruments for astronomical observations, and a deep dry well for observing the stars in the day-time. Lat. of the Observatory, 51° 28' 40" N. Lon. from St. Paul's, London, 0° 5' 47" E.

GREGOIE, an island of Africa, in the Jaquin, on the Gold Coast, where the Europeans have factories; 3 miles from the sea.

GREGORIAN CALENDAR, that which shews the new and full moon, with the time of Easter, and the moveable feasts depending thereon, by means of epacts disposed through the several months of the Gregorian year. See **CHRONOLOGY**.

GREGORIAN STYLE, the New Style, now used, which succeeded the Julian style, in Britain in 1752. See **CHRONOLOGY**.

GREGORIAN TELESCOPE. See **OPTICS**.

GREGORIAN YEAR. See **CHRONOLOGY**.

GREGORIO, St. an island of Maritime Austria, in the province of Quarnaro, three miles long, and half a mile broad. The natives deal chiefly in sheep, of which there are 2,500 on the island.

GREGORY XIII. was a native of Bologna, and succeeded Pius V. in 1572. He was the most deeply versed in the canon and civil law of any in his time. He ornamented Rome with many fine buildings, and several fountains. He corrected Gratian's Decretals, and wrote learned notes on them. But his chief merit lies in bringing about the reform of the Calendar, which was effected under his orders by Lewis Lilio, a Roman physician. See **CHRONOLOGY**. A short time before he died he received ambassadors from Japan, acknowledging the authority of the Holy See. He died in 1585, aged 83.

GREGORY, DAVID, F. R. S. Savilian professor of astronomy at Oxford, whom Dr. Smith has termed "subtilissimi ingenii mathematicus," the nephew of James Gregory abovementioned, was born at Aberdeen in 1661, and received the earlier parts of his education in that city. He completed his studies at Edinburgh; and, being possessed of the mathematical papers of his uncle, soon distinguished himself likewise as the heir of his genius. In the 23d year of his age, he was elected professor of mathematics in the university of Edinburgh; and published, in the same year, *Exercitatio Geometrica de Dimensione Figurarum sive Specimen Methodi generalis dimetiendi quasvis Figuras*, Edinburgh; 1684; 4to. He saw very early the excellence of the Newtonian philosophy; and had the merit of being the first who introduced it into the schools by his public lectures at Edinburgh. "He had (says Mr. Whiston) already caused several of his scholars to keep acts, as we call them, upon several branches of the Newtonian philosophy; whilst we at Cambridge, poor wretches, were ignominiously studying the fictitious hypothesis of the Cartesians." In 1691, on the report of Dr. Bernard's intension of resigning the Savilian professorship of astronomy at Oxford, David Gregory went to London; and being patronised by Sir Isaac Newton, and warmly befriended by Mr. Flamsteed, he obtained the vacant professorship, for which Dr. Halley was a competitor. This rivalry, however, instead of animosity, laid the foundation of friendship between these eminent men; and Halley soon after became the colleague of Gregory, by obtaining the professorship of geometry in the same university. Soon after his arrival in London, Mr. Gregory had been elected F. R. S. and, previously to his election into the Savilian professorship, had the degree of M. D. conferred on him by the university of Oxford. In 1693, he published in the *Philosophical Transactions* a resolution of the Florentine problem de Testudine veliformi quadrabili; and he continued to communicate to the public, from time to time, many ingenious mathematical papers by the same channel. In 1695, he printed at Oxford "*Catoptrica et Dioptrica Spherica Elementa*," a work which contains the substance of some of his public lectures at Edinburgh. This valuable treatise was republished first with additions by Dr. William Brown, with the recommendation of Mr. Jones and Dr. Desaguliers; and afterwards by the latter, with an appendix containing an account of the Gregorian and Newtonian telescopes, together with Mr. Hadley's tables for the construction of both those instruments. In the end of this treatise, there is an observation which shews, that what is generally believed to be a discovery of a much later date, the construction of achromatic telescopes, which has been carried to great perfection by Mr. Dollond and Mr. Ramsden, had occurred to the mind of David Gregory, from the reflection on the admirable contrivance of nature in combining the different humours of the eye. See *Catopt. et Dioptr. Sphær. Elem.* Oxon. 1695, p. 98. In 1702, our author published at Oxford, "*Astronomiæ Physicæ et Geometricæ Elementa*," a work which is accounted his master-piece. It is founded on the Newtonian doctrines, and was esteemed by Sir Isaac Newton himself as a most excellent explanation and defence of his philosophy. In 1703, he published a folio edition of Euclid in Greek and Latin. In this work, although it contains all the treatises attributed to Euclid, Dr. Gregory has been careful to point out such as he found reason, from internal evidence, to be the production of some inferior geometrician. Dr. Gregory engaged, soon after, with his colleague

Halley,

Halley, in the publication of Apollonius's Conics, but he had not proceeded far in this undertaking when he died, in the 49th year of his age, at Maidenhead in Berkshire, A. D. 1710. To the genius and abilities of David Gregory, the most celebrated mathematicians of the age, Sir Isaac Newton, Dr. Halley, and Dr. Keill, have given ample testimonies. Besides those works published in his lifetime, he left in MS. "A Short Treatise of the Nature and Arithmetic of Logarithms," which is printed at the end of Dr. Keill's translation of Commandine's Euclid; and "A Treatise of Practical Geometry," which was afterwards translated, and published in 1745, by Mr. Maclaurin. He married, in 1695, Elisabeth, the daughter of Mr. Oliphant of Langtown. By this lady he had four sons, of whom, the eldest, David, was appointed regius professor of modern history at Oxford by king George I. and died in 1767, in an advanced age, after enjoying for many years the dignity of dean of Christ church in that university.

GREGORY, JAMES, F. R. S. one of the most eminent mathematicians of the 17th century, was the second son of the Rev. Mr. Gregory, and was born at Aberdeen in 1638. His mother was a daughter of Mr. David Anderson of Finzaugh, a gentleman who possessed a singular turn for mathematics. This mathematical genius seems to have been hereditary in the family. Alexander Anderson, cousin-german of David, was professor of mathematics at Paris, and published there in 1612, "*Supplementum Apollonii Redivivi, &c.*" The mother of James Gregory inherited the genius of her family; and observing in her son, while yet a child, a strong propensity to mathematics, she instructed him herself in the elements of that science. He received his education in the languages at Aberdeen, and went through the usual course of academical studies in the Marischal college. At the age of 24 he published his treatise, entitled, "*Optica Promota, seu abdita Rationum Reflexorum et Refractorum Mysteria, Geometrice enucleata; cui Subnectitur Appendix Subtilissimorum Astronomice Problematorum Resolutionem Exhibens*;" London, 1663: a work of great genius, in which he gave the world an invention of his own, and one of the most valuable of the modern discoveries, the construction of the reflecting telescope. This discovery attracted the attention of the mathematicians, who were soon convinced of its great importance to the sciences of optics and astronomy. The manner of placing the two specula upon the same axis appearing to Sir Isaac Newton to be attended with the disadvantage of losing the central rays of the larger speculum, he proposed an improvement on the instrument, by giving an oblique position to the smaller speculum, and placing the eye-glass in the side of the tube. But the Newtonian construction of that instrument has been long abandoned for the original or Gregorian, which is now universally employed where the instrument is of a moderate size; though Mr. Herschel has preferred the Newtonian form for the construction of those immense telescopes, which of late years he has so successfully employed in observing the heavens. The university of Padua being then in high reputation for mathematical studies, James Gregory went thither soon after the publication of his first work; and fixing his residence there for some years, he published in 1667, "*Vera Circuli et Hyperbolæ Quadratura*;" in which he propounded another discovery of his own, the invention of an infinitely converging series for the areas of the circle and hyperbole. To these, when republished in 1668, he added a new work, intitled, "*Geometriæ Pars Universalis, inserviens Quantitatum Curvarum Transmutationi et Mensuræ*;" in which he is allowed to have shewn, for the first time, a method for the transmutation of curves. These works attracted the notice, and the correspondence, of the greatest mathematicians of the age, Newton, Huygens, Halley, and Wallis; and their author being soon after chosen F. R. S. of London, contributed to enrich the Philosophical Transactions by many valuable papers. Through this channel, he carried on a dispute with Mr. Huygens, occasioned by his treatise on the quadrature of the circle and hyperbole, to which that able mathematician had started some objections. Of this controversy, it is sufficient to say, that, in the opinion of Leibnitz, (who however allows Mr. Gregory the highest merit,) Mr. Huygens has pointed out, though not errors, some considerable deficiencies in the treatise above mentioned, and shewn a much simpler method of attaining the end in view. In 1668, Mr. Gregory published at London his "*Exercitationes Geometricæ*," which contributed still to extend his reputation. About this time he was elected pro-

fessor of mathematics in the university of St. Andrew's; an office which he held for six years. During his residence there, he married, in 1669, Mary, the daughter of George Jameson the celebrated painter, whom Mr. Walpole has termed the Vandyke of Scotland. In 1674, he was called to fill the mathematical chair in the university of Edinburgh. This place he had held for little more than a year, when, in October 1675, being employed in shewing the satellites of Jupiter through a telescope to some of his pupils, he was suddenly struck with total blindness, and died a few days after, at the early age of 37. He was a man of an acute and penetrating genius. His temper seems to have been warm, as appears from his dispute with Mr. Huygens; and, conscious perhaps of his own merits as a discoverer, he seems to have been jealous of losing any portion of his reputation by the improvements of others upon his inventions.

GREGORY, JOHN, a physician, was born in 1724, at Aberdeen, where his father, Dr. James Gregory, was professor of medicine in King's college. After studying at his native place he removed to Edinburgh, and from thence to Leyden. In 1745 he obtained the degree of doctor of physic, and became professor of philosophy at Aberdeen, which he exchanged in 1749 for that of physic. About 1751 he settled in London, and was chosen a fellow of the Royal Society. In 1764 he removed to Edinburgh, where in 1766 he was elected professor of physic. He died in 1773. His works are, on the "*Duties and Offices of a Physician*," 8vo.; "*Elements of the Practice of Physic*," 8vo.; "*A Father's Legacy to his daughters*," 12mo. All his pieces have been collected into four vols. 8vo.

GRIEFSWALD, a town of Swedish Pomerania, on the Rik, 15 miles S. E. of Stralsund.

GRENADA, one of the Caribbee islands. It is the last of the Windward Caribbees; and lies 30 leagues N. of New Andalusia, on the continent. According to some, it is 24 leagues in compass; according to others, only 22. It is 28 miles long, and in some places 15 broad. The chief port, formerly called Louis, now St. George's, stands on the W. side of the island, in the middle of a large bay, with a sandy bottom. It is said that 1000 barks, from 300 to 400 tons, may ride secure from storms; and that 100 ships, of 1000 tons each, may be moored in the harbour. The island abounds with game, fish, and very fine timber. A lake on a high mountain, about the middle of the island, supplies it with streams of fresh water. On the 10th June 1796, the French commandant, Jossey, surrendered all the French posts in this island by capitulation to the British under Gen. Abercrombie. At this time the British obtained complete possession on the 19th June; since to this island, which before had been in a distracted state, tranquillity has been restored. Lat. of Fort Royal in this island, 12° 2' 54" N. Lon. from Greenwich, 61° 51' 15" W.

GRENADÉ, [from *pomum granatum*, Lat.] a little hollow globe or ball of iron, or other metal, about two inches and a half in diameter, which, being filled with fine powder, is set on fire by means of a small fusee fastened to the touch-hole; as soon as it is kindled, the case flies into many shatters, much to the damage of all that stand near it. Grenades, or Grenadoes, are thrown by the grenadiers into those places where the men stand thick, particularly into trenches and other lodgements made by the enemy. They were invented about 1594. The author of the Military Dictionary has the following remark on the use of Grenades: "Grenades have unaccountably sunk into disuse, but I am persuaded there is nothing more proper than to have grenades to throw among the enemy who have jumped into the ditch. During the siege of Cassel, under Count de La Lippe, in the campaign of 1762, a young engineer undertook to carry one of the outworks with a much smaller detachment than one which had been repulsed, and succeeded with ease from the use of grenades; which is a proof that they should not be neglected, either in the attack or defence of posts." The word Grenado takes its rise from the shell being filled with grains of powder as a pomegranate is with kernels.

GRENADIERS are armed with a sword, a firelock, a bayonet, and a pouch full of hand-grenades. They wear high caps, are generally the tallest and briskest fellows, and are always the first upon all attacks. Every battalion of foot has generally a company of them; or else four or five grenadiers belong to each company of the battalion, which, on division, are drawn out, and form a company of themselves. These always take the right of the battalion.

GRENAILLE, a name given by the French writers to a preparation of copper, which the Chinese use as a red colour in some of their finest china, particularly for that colour which is called oil-red or in red-oil.

GRENOBLE, a town of France, in the department of Isere, and late province of Dauphiny, anciently called Accusium Colonia. Lat. 45° 11' 42" N. Lon. from Greenwich 5° 43' 34" E.

GRESHAM, SIR THOMAS, an opulent merchant in London, descended from an ancient family of Norfolk. He was born in 1519. His father was king's agent at Antwerp, for taking up money of the merchants. Being appointed to the same office, he, in 1551, removed to that city with his family. This employment was suspended on the accession of queen Mary, but, on proper representation, was restored to him again. Queen Elizabeth knighted him, and made him her agent in foreign parts. About this time, he built a large mansion-house on the W. side of Bishopsgate-street, since named Gresham College. His father had proposed building a house or exchange for the merchants to meet in, instead of walking in the open street; but Sir Thomas went beyond his father: he offered, if the citizens would provide a proper piece of ground, to build a house at his own expence; which being accepted, he fulfilled his promise after the plan of the exchange at Antwerp. On the 29th of Jan. 1570, when the new edifice was opened, the queen came and dined with the founder; and caused a herald with a trumpet to proclaim it by the name of the Royal Exchange. In pursuance also of a promise to endow a college for the profession of the seven liberal sciences, he made a testamentary disposition of his house in London for that purpose, now Gresham College. He left several other benefactions, and died in 1579. He had a mind every way suited to his fortune, generous and benign; ready to perform good actions, and encourage them in others. He was a great friend and patron of the celebrated martyrologist, John Fox. He was well acquainted with the ancient and several modern languages; he had a very comprehensive knowledge of all affairs relating to commerce, foreign and domestic; and his success was equal to it, being esteemed the highest commoner in England, in his time. He transacted queen Elizabeth's mercantile affairs so constantly, that he was called "the royal merchant;" and his house was sometimes appointed for the reception of foreign princes, upon their first arrival in London.

GRETNA GREEN. See **GRAITNEY**.

GREWIA, in botany, a genus of the polyandria order, and gynandria class of plants; natural order, Colunniferae. Calyx pentaphyllous; petals five, each with a nectariferous scale at the base; berry quadrilocular. There are thirteen species.

GREY, Lady JANE, a most illustrious and unfortunate lady, descended of the blood royal of England by both parents, was the eldest daughter of Henry Grey marquis of Dorset, and Frances the daughter of Charles Brandon lord Suffolk, by Mary the dowager of Lewis XII. king of France, who was the youngest daughter of Henry VII. king of England. She was born in 1537, at Broadgate, her father's seat in Leicestershire. She discovered an early propensity to all kinds of literature; and having a fine genius, improved under the tuition of Mr. Elmer, she made a most surprising progress in the languages, arts, and sciences. She understood perfectly both kinds of philosophy, and could express herself very properly in Latin and Greek; and Sir Thomas Chaloner (in Strype's Memorials, Vol. III. p. 93.) says, that she was well versed in Hebrew, Chaldee, Arabic, French, and Italian. He adds, that "she played well on instrumental music, writ a curious hand, and was excellent at the needle;" and that she accompanied her musical instruments with a voice exquisitely sweet, assisted by all the graces that art could bestow. In 1553, the dukes of Suffolk and Northumberland, who were now, after the fall of Somerset, arrived at the height of power, began, on the decline of king Edward's health, to think how to prevent that reverse of fortune which, as things then stood, they foresaw must happen upon his death. To obtain this end, no other remedy was judged sufficient but a change in the succession of the crown, and transferring it into their own families, by rendering Lady Jane queen. Those most excellent and amiable qualities, which had rendered her dear to all who had the happiness to know her, joined to her near affinity to the king, subjected her to become the chief tool of an ambition not her own. With this view she was married to lord Guildford Dud-

ley, fourth son of the duke of Northumberland, without discovering to her the real design of the match; which was celebrated with great pomp in the end of May; and was so much to the king's satisfaction, that he contributed bounteously to the expence of it from the royal wardrobe. Edward VI. died in July following; and Lady Jane, with infinite reluctance, overpowered by the solicitations of her ambitious friends, allowed herself to be proclaimed queen of England, on the strength of a deed extorted from that prince by her father-in-law the duke of Northumberland, which set aside the succession of queen Mary, queen Elizabeth, and Mary queen of Scots. Her regal pageantry continued but a few days. Queen Mary's hereditary right prevailed; and the unfortunate Lady Jane Grey and her husband were committed to the Tower, and on the 13th Nov. arraigned and found guilty of high treason. On the 12th February following they were both beheaded on Tower-hill. Her magnanimity in this dreadful scene was astonishing. Immediately before her execution, she addressed herself to the weeping multitude with amazing composure and coherency; and died in charity with that wretched world which she had so much reason to execrate. Thus did the pious Mary begin her reign with the murder of an innocent young creature of 18; who, for simplicity of manners, purity of heart, and extensive learning, was hardly ever equalled in any age or country. But, alas! Jane was an obstinate heretic! Fleckenham, Mary's chaplain, visited her in the tower and tried to convert her to the catholic faith, but found her far his superior in argument. Her writings are, 1. Four Latin Epistles; three to Bullenger, and one to her sister lady Catharine. The last was written the night before her execution, in a blank leaf of a Greek Testament. These letters are printed in a work entitled *Epistolæ Helveticæ Reformatioribus, vel ad eos scriptæ*, &c. Tiguri, 1742, 8vo. 2. Her Conference with Fleckenham. Ballard. 3. A letter to Dr. Harding, her father's chaplain. Printed in the Phoenix, vol. ii. p. 28. 4. A Prayer for her own Use during her Confinement. In Fox's Acts and monuments. 5. Four Latin verses; written in prison with a pin. They are as follows:

Non aliena putes, homini quæ abtingere possunt :
Sors hodierna mihi, tunc erit illa tibi.

Jane Dudley.

Deo juvante, nil nocet livor malus :

Et non juvante, nil juvat labor gravis.

Post tenebras spero lucem.

9. Her speech on the Scaffold. Ballard. It began thus: "My Lords, and you good Christian people who come to see me die; I am under a law, and by that law, as a never-erring judge, I am condemned to die: not for any thing I have offended the queen's majesty; for I will wash my hands guiltless thereof, and deliver to my God a soul as pure from such trespass as innocence from injustice; but only for that I consented to the thing I was enforced unto, constraint making the law believe I did that which I never understood." &c.—Hollingshed, Sir Richard Baker, Bale, and Fox, tell us that she wrote several other things, but do not mention where they are to be found.

GREY, RICHARD, D. D. a learned English divine, born in 1693, and educated at the university of Oxford, where he took the degree of M. A. in 1719. He obtained the rectories of Kilnecote in Leicestershire and Hindon in Northamptonshire, with other benefices. He published many sermons and religious tracts; besides the following: 1. *Memoria Technica*, or a New Method of Artificial Memory; of which the first edition was printed in 1730, and a fourth in 1756. 2. *A System of English Ecclesiastical Law*, 8vo. 1741. 3. *The miserable and distracted State of Religion in England, upon the Downfall of the Church established*; 8vo. 1736. 4. *A new and easy Method of learning Hebrew without Points*, 1738. 5. *Historia Josephi*, and 6. *Paradigmata Verborum*, 1739. 7. *Liber Jobi*, 1742. 8. *Answer to Warburton's Remarks*, 1744. 9. *Nova Methodus Hebraicæ discendi*, &c. 1751. 10. *A Translation of Mr. H. Browne's poem, De Animi Immortalitate*. He was married; and died Feb. 23, 1771, aged 78, leaving several daughters.

GREY-HOUND. See **CANIS**.

GRIS, in botany, a genus of the monogynia order, and polyandria class of plants: corolla four-petaled; calyx four-cleft; stigma sessile, cross-shaped; drupe with an eight-furrowed nucleus. There is but one species, viz. *G. cauliflora*, anchovy-pear.

pear. This tree is about fifty feet in height, branching at the top; leaves on short petioles, pendulous, two or three feet long; flowers from the stem, on short, scaly, many-flowered peduncles. It is a native of Jamaica.

GRIEF, one of the passions, the influence of which on the body is very great. Its effects resemble in several instances those of fear, with, however, some variations, owing perhaps to its being in general of longer duration. Grief diminishes the bodily strength in general, and particularly the force of the heart and circulation; as appears by the frequent sighs and deep respirations which attend it, which seem to be necessary exertions, in order to promote the passage of the blood through the lungs. It diminishes perspiration, obstructs the menstrual discharge, produces paleness of the skin, and oedematous complaints, and scirrhus of the glandular parts. It aggravates the scurvy, and the malignity of putrid and contagious distempers; and renders people more apt to receive the infection of them. When it comes on suddenly, and in a great degree, it causes a palpitation of the heart, and renders the pulse irregular. Blindness, gangrene, and sudden death, have followed the excess of this sensation. Its effects of changing the colour of the hair are well known. Opiates in small doses, are good cordials in this case.

GRIELUM, in botany, a genus of the pentagynia order, and decandria class of plants. Calyx quinquefid; petals five, filaments persisting. One species, a Cape plant.

GRIERSON, **CONSTANTIA**, a native of the county of Kilkenny in Ireland, was one of the most learned women on record, though she was born of poor parents, and died at the age of 27, in 1733. She was an excellent Greek and Latin scholar; and understood history, divinity, philosophy, and mathematics. She proved her skill in Latin by her dedication of the Dublin edition of Tacitus to Lord Carteret, and by that of Terence to his son; to whom she also addressed a Greek epigram. She wrote many elegant English poems, several of which were inserted by Mrs. Barber among her own. When Lord Carteret was lord lieutenant of Ireland, he obtained a patent for Mr. Grierson to be the king's printer; and to reward the uncommon merit of his wife, caused her life to be included in it.

GRIFENHAKEN, a town of Prussian Pomerania, in the duchy of Stettin, on the Oder. Lon. 14. 42. E. Lat. 53. 25. N.

GRIFIN, or **GRIFTON**, [this should rather be written *gryfon*, or *gryphon*; *gryps*, γρυψ,] a fabled animal said to be generated between the lion and eagle, and to have the head and paws of the lion, and the wings of the eagle. The Griffin, Gryphus, by the ancients, was supposed to have four legs, wings, and a beak; the upper part representing an eagle, and the lower a lion; and to watch over gold-mines, hidden treasures, &c. This imaginary animal was consecrated to the sun; and the ancient painters represented the chariot of the sun as drawn by griffons. M. Spanheim observes the same of those of Jupiter and Nemesis. The griffin is commonly seen on ancient arms; and is borne in coat-armour. Guillim blazons it rampant; alleging, that any very fierce animal may be blazoned as well as the lion. Sylvester, Morgan, and others, use the terms segreiant instead of rampant. The griffin is also an ornament of architecture in constant use among the Greeks, and was copied from them, with the other elegancies of architectural enrichments, by the Romans.

GRIFON in Scripture is that species of the eagle called in Latin *ossifraga*, the osprey; and פֶּרֶס, of the verb פָּרַס, *para*, to break. See **FALCO**.

GRIMBERGEN, a town of France, in the department of Dyle, and late province of Austrian Brabant, six miles N. of Brussels.

GRIMM, or **GRIMMA**, a town of Upper Saxony, in Leipsic, 42 miles W. N. W. of Dresden.

GRIMMEN, or **GRIMN**, a town of Pomerania, 14 miles S. of Stralsund. Lon. 13. 27. E. Lat. 54. 12. N.

GRIMSBY, a large sea-port town of England, in Lincolnshire, 169 miles from London.

GRIND, an island near the coast of Friesland, 9 miles N. N. W. of Harlingen.

GRINDING, or **TRITURATION**, the act of breaking or comminuting a solid body, and reducing it into powder. See **LEVIGATION**, and **PULVERISATION**. The painters' colours are ground on a marble or porphyry, either with oil or gum-water.

GRINDING is also used for rubbing or wearing off the irregular parts of the surface of a body, and reducing it to the destined figure, whether that be flat, concave, or the like. The grinding and polishing of glass is a considerable art; for which see **GLASS-MAKING**; and, for grinding of optical glasses, see **OPTICS**.

GRINSTED, **West**, a town in Sussex, 43 miles from London.

GRINSTED, **EAST**, a borough in Sussex, 29 miles S. of London.

GRIPE, in the sea-language, is a piece of timber fayed against the lower piece of the stern, from the fore-mast end of the keel joining with the knee of the head: its use is to defend the lower part of the stern from any injury; but it is often made the larger, to make the ship keep a good wind.

GRIPE OF A SHIP, is also the compass or sharpness of the stern under water, chiefly towards the bottom of it.

GRIPE, is also a sea-term, for a ship's turning her head more to the wind than she should; this is caused either by over-loading her a-head, the weight of which presses her down, so that she will not readily fall off from the wind; or by staying or setting her masts too much aft; which is always a fault in short ships that draw much water, since it causes them to be continually running into the wind: though in floating ships, if the masts be not stayed very far aft, they will never keep a good wind.

GRIPES, in medicine, a sort of colic or painful disorder of the lower belly, occasioned by some sharp pungent matters vellicating the parts, or by wind pent up in the intestines. See **MEDICINE**.

GRISGRIS, a superstition greatly in vogue among the negroes in the interior parts of Africa. The grisgris, according to Le Maire, are certain Arabic characters mixed with magical figures drawn by the Marabuts or priests upon paper. Labat affirms, that they are nothing else than scraps of the alcoran in Arabic. The poorest negro never goes to war without his grisgris, as a charm against wounds; and if it prove ineffectual, the priest transfers the blame on the immorality of his conduct.

GRISLEA, in botany, a genus of the monogynia order, and octandria class of plant; natural order, Calycanthemæ. Calyx quadrifid; petals four, one from each incisure of it; capsule, globose, superior, unilocular, and polyspermous. There are two species.

GRISONS, a people situated among the Alps, and long allies of the Swiss, but now united with the Helvetic republic. Their country is bounded on the N. by the late countries of Sargans and Bludenz, and the canton of Glaris. The length is about 70 miles, and the breadth about 60. The inhabitants are said to have been named Grisons, from the grey coats they wore in former times. This country, lying among the Alps, is very mountainous; but the mountains yield good pasture for the cattle, sheep, and goats, with some rye and barley; in the vallies there is plenty of grain, pulse, fruits, and wine. It abounds also with hogs and wild fowl; but there is a scarcity of fish and salt, and their horses are mostly purchased of foreigners. The principal rivers are the Rhine, the Inn, and the Adda. It has also several lakes, most of which lie on the tops of the hills. The language of the Grisons is either a corrupt Italian or the German.

GRIT, a genus of argillaceous earths. Its texture is more or less porous, equable, and rough to the touch. It does not give fire with steel, nor effervesce with acids. When fresh broken and breathed upon, it exhales an earthy smell. Its specific gravity is from 2, to 2.6; and so unfusible as to be used for fire-stones. It is also used for millstones and whetstones; and sometimes for filtering stones and for buildings.

GROAIX, an isle in the Atlantic, on the W. coast of France, four miles long and $1\frac{1}{2}$ broad; 18 miles N. N. W. of Belle-isle.

GROCERS anciently were such persons as engrossed all merchandize that was vendible; but now they are incorporated, and make one of the companies of the city of London.

GRODNO, a large town of Lithuania, in the palatinate of Wilna, 140 miles N. E. of Warsaw.

GROIN, among builders, is the angular curve made by the intersection of two semi-cylinders or arches; and is either regular or irregular. A regular groin is when the intersecting arches, whether semicircular or semielliptical, are of the same diameters and heights.

heights. An irregular groin is where one of the arches is semi-circular, and the other semielliptical.

GROLL, a town of Batavia, in the department of the Rhine, and late county of Zutphen, 19 miles E. of Zutphen, and 19 S.S.W. of Oldenzael.

GROMETS, in the sea-language, small rings formerly fastened with staples to the yards, to make fast the gaskets, but now never used.

GRONINGEN, the most northerly of the late Seven United Provinces, was about 47 miles long, and 33 miles broad. It has rich pastures, large herds of cattle, plenty of sea and river fish, and of turf, with some forests and corn-land.

GRONINGEN, a strong city of Batavia, in the department of Eems, and late capital of the above province.

GRONOVIA, in botany, a genus of the monogynia order, and pentandria class of plants; natural order, Cucurbitaceæ. Petals five, together with the stamens inserted into the bell-shaped corolla; berry dry, inferior, containing one seed. There is but one species, viz. *G. scandens*, climbing gronovia, an annual plant.

GRONOVIVS, JOHN FREDERIC, a very learned critic, was born at Hamburgh in 1613; and having travelled through Germany, Italy, and France, was made professor of polite learning at Deventer, and afterwards at Leyden, where he died in 1671. He published, 1. *Diatrise in Statii*, &c. 2. *De Sestertiis*. 3. *Correct editions of Seneca, Statius, Livy's, Pliny's Natural History, Tacitus, Aulus Gellius, Phædrus*, &c. with notes; and other works.

GRONOVIVS, JAMES, son of the preceding, and a very learned man, was educated first at Leyden, then went over to England, where he visited the universities, consulted the curious MSS. and formed an acquaintance with several learned men. He was chosen by the grand duke to be professor at Pisa, with a considerable salary. He returned into Holland, after he had resided two years in Tuscany, and consulted the MSS. in the Medicean library. In 1679, he was invited by the curators of the university to a professorship; and his inaugural dissertation was so highly approved of, that the curators added 400 florins to his stipend, and continued it to his death in 1716. His principal works are, "*The Treasure of Greek Antiquities*," in 13 vols. folio; and a great number of dissertations and editions of ancient authors. He was compared to Schioppus for the virulence of his style; and the severity, with which he treated other great men who differed from him, exposed him to just censure.

GROOM, a name particularly applied to several superior officers belonging to the king's household, as groom of the chamber, groom of the stole.

GROOM-PORTER, an officer of the king's household, who provides chairs, stools, and firing, for the king's lodging, and also furnishes cards, dice, &c. and decides the disputes which arise at play.

GROOM is more particularly used for a servant appointed to attend on horses in the stable. It is his business to feed and water them, to curry and rub them down, and to keep a watchful eye over them, that they may have no inward or outward disorder, without his discovering it, and using his endeavours to remove it.

GROOVE, among miners, is the shaft or pit sunk into the earth, sometimes in the vein, and sometimes not.

GROOVE, among joiners, the channel made by their plough in the edge of a moulding, style, or rail, to put their pannels in, in wainscotting.

GROOVE also denotes a gardener's tool for transplanting plants.

GROSE, FRANCIS, Esq. F. A. S. an eminent English antiquary, the son of Francis Grose, Esq. jeweller, of Richmond, who fitted up the coronation-crown of king George II. He was born in 1731, and was left an independent fortune; but had not a disposition to preserve it. He wrote, 1. *The Antiquities of England and Wales*, in 8 vols. 4to. and 8vo, which he began in 1773; and completed in 1787; containing 589 views, besides 40 plans, &c. 2. *The Antiquities of Scotland*, 2 vols. 4to. and 8vo, containing 190 views with a map. 3. *The Antiquities of Ireland*, 2 vols. 4to. and 8vo. 4. *A Treatise on Ancient Armour and Weapons*, 4to. 1785; with a supplement in 1789. 5. *A Classical Dictionary of the Vulgar Tongue*; 8vo. 1785. 6. *Military Antiquities*; 2 vols. 4to. 1786—88. 7. *The History of Dover Castle*; 4to. 1786. 8. *A*

Provincial Glossary, with a collection of Local Proverbs and Popular Superstitions; 8vo. 1788. 9. *A Guide to Health, Beauty, Honour, and Riches*; 8vo. 10. *Rules for Drawing Caricatures*; 8vo. 1788. 11. *The Olio*; a collection of Essays; 8vo. In summer, 1789, he set out on a tour in Scotland, and began to communicate his observations in folio numbers, with four plates each, in 1790. Before he had completed this work, he went to Dublin, with the intention of executing a similar work, with views and descriptions of the antiquities of Ireland, executed in the same elegant manner with those of Great Britain: but being seized with an apoplectic fit, at the house of Mr. Hone in Dublin, he died on the 12th May, 1791, aged about 60. He had a great talent for drawing, which peculiarly qualified him for executing the works in which he engaged; and, being of an agreeable, humorous, and communicative disposition, he was much esteemed in the extensive circle of his friends. He visited almost every part of the three kingdoms, and was every where well received. His humour was of that genuine kind, which exhilarates without offending either against virtue or good manners.

GROSS, a foreign money, in divers countries, answering to our groat.

GROSS, [GROSSUS,] in our ancient law-writers, denotes a thing absolute, and not depending on another. Thus, villain in gross, villanus in grosso, was a servant, who did not belong to the land, but immediately to the person of the lord; or a servile person not appendant or annexed to the land or manor, and to go along with the tenures as appurtenant to it; but like other personal goods and chattels of his lord, at his lord's pleasure and disposal.

GROSS WEIGHT, the weight of merchandizes and goods, with their dust and dross, as also of the bag, cask, chest, &c. wherein they are contained; out of which gross weight, allowance is to be made of tare and tret.

GROTESQUE, or **GROTESK**, in sculpture and painting, something whimsical, extravagant, and monstrous; consisting either of things that are merely imaginary or so distorted, as to raise surprise and ridicule. The word owes its derivation from figures of this kind, being anciently much used to adorn the grottos wherein the tombs of eminent persons were inclosed. Such was that of Ovid, whose grotto was discovered near Rome about 100 years ago.

GROTIUS, HUGO, or more properly HUGH DE GROOT, one of the greatest men of his age, was born at Delft in 1583. He made so rapid a progress in his studies, that at 15 he had attained great knowledge in philosophy, divinity, and civil law; and a yet greater proficiency in polite literature, as appeared by the commentary he had made at that age on Martians Capella. In 1598, he accompanied the Dutch ambassador into France, and was honoured with several marks of esteem by Henry IV. He took his degree of LL. D. in that kingdom; and at his return to his native country, pleaded at the bar before he was 17 years of age. He was not 24 when he was appointed attorney-general. In 1613 he settled at Rotterdam, and was nominated syndic of that city; but did not accept of the office, till a promise was made him that he should not be removed from it. This prudent precaution he took from his foreseeing, that the quarrels of the divines on the doctrine of grace, which had already given rise to many factions in the state, would occasion revolutions in the chief cities. The same year he was sent to England, on account of the divisions that reigned between the traders of the two nations, on the right of fishing in the northern seas; but he could obtain no satisfaction. He was afterwards sent to England, to persuade the king and the principal divines to favour the Arminians; and he had several conferences with K. James I. on that subject. On his return to Holland, his attachment to Barneveldt involved him in great trouble; for he was seized, and sentenced to perpetual imprisonment in 1619, and to forfeit all his goods and chattels. But after having been treated with great rigour for above a year and a half in his confinement, he was delivered by the advice and artifice of his wife, who having observed that his keepers had often fatigued themselves with searching and examining a great trunk full of foul linen, which used to be washed at Gorkum, but now let it pass without opening it, she advised him to bore holes in it to prevent his being stifled, and then to get into it. He complied with this advice, and was carried to a friend's house in Gorkum; where dressing himself like a mason, and taking a rule and trowel, he passed

passed through the market-place, and stepping into a boat went to Valvet in Brabant. Here he made himself known to some Arminians, and hired a carriage to Antwerp. At first there was a design of prosecuting his wife, who staid in the prison; and some judges were of opinion that she ought to be kept there in her husband's stead: however, she was released by a plurality of voices, and universally applauded for her behaviour. He now retired into France, where he met with a gracious reception from that court, and Lewis XIII. settled a pension upon him. Having resided there 11 years, he returned to Holland, on his receiving a very kind letter from Frederic Henry prince of Orange; but his enemies renewing their persecution, he went to Hamburgh; where, in 1634, Q. Christina of Sweden made him her counsellor, and sent him ambassador into France. After having discharged the duties of this office above 11 years, he returned to give an account to Q. Christina of his embassy; when he took Holland in his way, and received many honours at Amsterdam. He was introduced to her at Stockholm; and there begged that she would grant his dismissal, that he might return to Holland. This he obtained with difficulty; and the queen gave him many marks of her esteem, though he had many enemies at her court too. As he was returning, the ship in which he embarked was cast away on the coast of Pomerania; and being sick, he continued his journey by land; but he was forced to stop at Rostock, where he died on the 28th Aug. 1645. His body was carried to Delft, to be interred in the sepulchre of his ancestors. Notwithstanding the embassies in which he was employed, he composed a great number of excellent works; the principal of which are, 1. *De Jure Belli et Pacis*, which is esteemed a master-piece: 2. *A Treatise on the Truth of the Christian Religion*: 3. *Commentaries on the holy Scripture*: 4. *The History and Annals of Holland*: and 5. *A great number of letters*: All written in Latin.

GROTSKAW, or **GROTSKAW**, a town of European Turkey in the province of Servia.

GROTSKAW, a province of Silesia.

GROTSKAW, a strong town, capital of the above province, seated in a fruitful plain.

GROTTGAU, or **GROTTKAU**, a town and territory of Silesia, in the principality of Neisse, 14 miles N. of Neisse.

GROTTO, [*grotte*, French; *grotta*, Italian,] a cavern or cave made for coolness.

GROTTO, or **GROTTA**, in natural history, a large deep cavern or den in a mountain or rock. The word is formed, according to Menage, &c. from the Latin *crypta*. Du Cange observes, that *grotta* was used in the same sense in the corrupt Latin. The ancient anchorites retired into dens and grottos, to apply themselves the more attentively to meditation. Elden Hole, Okey-hole, Peake's Hole, and Pool's Hole, are famous among the natural caverns or grottos of England. In grottos are frequently found crystals of the rock, stalactites, and other natural congelations, and those of an amazing beauty.

GROTTO, is also used for a little artificial edifice made in a garden, in imitation of a natural grotto. The outsides of these grottos are usually adorned with rustic architecture, and their inside with shell-work, fossils, &c. finished likewise with jets d'eau or fountains, &c. A cement for artificial grottos may be made thus: Take two parts of white rosin, melt it clear, and add to it four parts of bees wax; when melted together, add two or three parts of the powder of the stone you design to cement, or so much as will give the cement the colour of the stone; to this add one part of flower of sulphur: incorporate all together over a gentle fire, and afterwards knead them with your hands in warm water. With this cement the stones, shells, &c. after being well dried before the fire, may be cemented. Artificial red coral-branches, for the embellishment of grottos, may be made in the following manner: Take clear rosin, dissolve it in a brass-pan; to every ounce of which add two drachms of the finest vermilion: when you have stirred them well together, and have chosen your twigs and branches, peeled and dried, take a pencil, and paint the branches all over whilst the composition is warm; afterwards shape them in imitation of natural coral. This done, hold the branches over a gentle coal-fire, till all is smooth and even as if polished. In the same manner white coral may be prepared with white-lead, and black coral with lamp-black. A grotto may be built with little expence, of glass, cinders, pebbles, pieces of large flint, shells, moss, stones,

counterfeit coral, pieces of chalk, &c. all bound or cemented together with the above described cement.

GROTTO DEL CANI, a little cavern near Pozzuoli, 12 miles from Naples, the steams whereof are of a noxious quality; whence also it is called *bocca venenosa*, the poisonous mouth. "Two miles from Naples (says Dr. Mead), just by the Lago de Agnano, is a celebrated mofeta, commonly called la Grotta del Cani, and equally destructive to all within the reach of its vapours. It is a small grotto about eight feet high, 12 long, and 6 broad; from the ground arises a thin, subtle, warm fume, visible enough to a discerning eye, which does not spring up in little parcels here and there, but in one continued stream, covering the whole surface of the bottom of the cave; having this remarkable difference from common vapours, that it does not like smoke disperse into the air, but quickly after its rise falls back again, and returns to the earth; the colour of the sides of the grotto being the measure of its ascent: for so far it is of a darkish green, but higher only common earth. And as I myself found no inconveniency by standing in it, so no animal, if its head be above this mark, is the least injured. But when, as the manner is, a dog, or any other creature, is forcibly kept below it; or, by reason of its smallness, cannot hold its head above it, it presently loses all motion, falls down as dead, or in a swoon; the limbs convulsed and trembling, till at last no more signs of life appear than a very weak and almost insensible beating of the heart and arteries; which, if the animal be left a little longer, quickly ceases too, and then the case is irrecoverable; but if it be snatched out, and laid in the open air, it soon comes to life again, and sooner, if thrown into the adjacent lake." The fumes of the grotto, the same author argues, are no real poison, but act chiefly by their gravity; else the creatures could not recover so soon, or if they did, some symptoms, as faintness, &c. would be the consequence of it. He adds, "that in creatures killed therewith, when dissected, no marks of infection appear; and that the attack proceeds from a want of air, by which the circulation tends to an entire stoppage; and this so much the more, as the animal inspires a fluid of a quite different nature from the air, and so in no respect fit to supply its place. Taking the animal out, while yet alive, and throwing it into the neighbouring lake, it recovers: this is owing to the coldness of the water, which promotes the contraction of the fibres, and so assists the retarded circulation; the small portion of air which remains in the vesiculae, after every expiration, may be sufficient to drive out the noxious fluid."

GROTTO, or **GROTTA DEL SERPI**, a subterraneous cavern near the village of Safia, 8 miles from Braccano in Italy, is described by Kircher thus: "The grotta del serpi is big enough to hold two persons. It is perforated with several fistular apertures, somewhat in the manner of a sieve; out of which, at the beginning of the spring-season, issues a numerous brood of young snakes of divers colours but all free from any particular poisonous quality. In this cave they expose their lepers, paralytics, arthritics, and elephantiac patients, quite naked; where, the warmth of the subterraneous stream resolving them into a sweat, and the serpents clinging variously all around, licking and sucking them, they become so thoroughly freed of all their vitious humours, that, upon repeating the operation for some time, they become perfectly restored." This cave Kircher visited himself; and found it warm, and every way agreeable to the description given of it.

GROVE, in gardening, a small wood impervious to the rays of the sun. Groves are not only great ornaments to gardens; but also afford great relief against the violent heats of the sun, affording shade to walk under in the hottest parts of the day, when the other parts of the garden are useless; so that every garden is defective which has not shade.

GROVES have been in all ages held in great veneration. The proseuchae, and high places of the Jews, whither they resorted for the purposes of devotion, were probably situated in groves: see Joshua xxiv. 26. The proseuchae in Alexandria, mentioned by Philo, had groves about them because he complains that the Alexandrians, in a tumult against the Jews, cut down the trees of their proseuchae. The ancient Romans had a sort of groves near several of their temples, which were consecrated to some god, and called *luci*, by an antiphrasis, a *non lucendo*, as being shady and dark. The veneration which the ancient Druids had for groves is well known.

GROUND, in etching, denotes a gumous composition smeared

ed over the surface of the metal to be etched, to prevent the aquafortis from eating except in such places where this ground is cut through with the point of a needle. See ETCHING.

GROUND, in painting, is properly understood of such parts of the piece, as have nothing painted on them, but retain the original colour upon which the other colours are applied to make the representations. A building is said to serve as a good ground to a figure when the figure is painted on the building. The ground behind a picture in miniature, is commonly blue or crimson imitating a curtain of satin or velvet.

GROUND-ANGLING, fishing under water without a float, only with a plumb of lead, or a bullet, placed about nine inches from the hook; which is better, because it will roll on the ground. This method of fishing is most proper in cold weather, when the fish swim very low. The morning and evening are the chief seasons for the ground-line in fishing for trout; but if the day prove cloudy, or the water muddy, you may fish at ground all day.

GROUND-IVY, in botany. See GLECHOMA.

GROUND-NUTS. See ARACHIS.

GROUND-PINE, in botany. See TEUCURIUM.

GROUNDSEL. See BACCHARIS and SENECIO.

GROUND-TACKLE, a ship's anchors, cables, &c. and in general whatever is necessary to make her ride safe at anchor.

GROUPE, [*groupe*, Fr. *gropo*, Ital.] in painting and sculpture, is an assemblage of two or more figures of men, beasts, fruits, or the like, which have some apparent relation to each other. See PAINTING.

GROUP ISLANDS, or the **GROUFS**, a cluster of islands lately discovered in the South Sea. They lie in about S. Lat. 18. 12. and W. Lon. 142. 42.

GROUTHEAD, or **GREATHEAD**, **ROBERT**, a learned bishop of Lincoln, born at Stow, in Lincolnshire, or Stradbrook, in Suffolk, in the end of the 12th century. His parents were so poor, that when a boy he was obliged to do the meanest offices, and even to beg his bread; till the mayor of Lincoln, struck with his appearance and the quickness of his answers to certain questions, took him into his family, and put him to school. Here his ardent love of learning, and admirable capacity for acquiring it, soon appeared, and procured him many patrons, who enabled him to prosecute his studies, first at Cambridge, afterwards at Oxford, and at last at Paris. In these three famous seats of learning, he spent many years in the most indefatigable pursuit of knowledge, and became one of the best and most universal scholars of the age. He was master not only of the French and Latin, but also of the Greek and Hebrew languages, which was a very rare accomplishment in those times. Roger Bacon, who was intimately acquainted with him, says, that he spent much of his time for almost forty years in the study of geometry, astronomy, optics, and other branches of mathematical learning, in all which he very much excelled. Theology was his favourite study, in which he read lectures at Oxford with great applause. In the mean time, he obtained several preferments in the church, and was at length elected and consecrated bishop of Lincoln, A. D. 1235. In this station he soon became very famous, by the purity of his manners, the popularity of his preaching, the vigour of his discipline, and the boldness with which he reprov'd the vices and opposed the arbitrary mandates of the court of Rome; of this last we shall give one example. Pope Innocent IV. had granted to one of his own nephews, named Frederic, who was but a child, a provision to the first canon's place in the church of Lincoln that should become vacant; and sent a bull to the Archbishop of Canterbury, and Innocent, then papal legate in England, commanding them to see the provision made effectual; which they transmitted to the Bishop of Lincoln. But that brave and virtuous prelate boldly refused to obey this unreasonable mandate, and sent an answer to the papal bull containing the following severe reproaches against his holiness for abusing his power: "If we except the sins of Lucifer and Antichrist, there neither is nor can be a greater crime, nor any thing more contrary to the doctrine of the gospel, or more odious and abominable in the sight of Jesus Christ, than to ruin and destroy the souls of men, by depriving them of the spiritual aid and ministry of their pastors. This crime is committed by those who command the benefices intended for the support of able pastors, to be bestowed on those who are incapable of performing

the duties of the pastoral office. It is impossible therefore that the holy apostolic see, which received its authority from the Lord Jesus Christ, for edification, and not for destruction, can be guilty of such a crime, or any thing approaching to such a crime, so hateful to God and so hurtful to men. For this would be a most manifest corruption and abuse of its authority, which would forfeit all its glory, and plunge it into the pains of hell." Upon reading this letter, his holiness became frantic with rage, and threatened to make the bishop an object of terror and astonishment to the whole world. "How dare (said he) this old, deaf, doating fool, disobey my commands? Is not his master the King of England my subject, or rather my slave? Cannot he cast him into prison, and crush him in a moment?" But the cardinals brought the pope to think more calmly, and to take no notice of this letter. "Let us not (said they) raise a tumult in the church without necessity, and precipitate that revolt and separation from us, which, we know, must one day take place." Remarkable words, when we reflect when and by whom they were spoken! The bishop did not long survive this noble stand against the gross corruptions and tyranny of the church of Rome. He fell sick at his castle of Bugden that same year; and sensible that his death was drawing near, he called his clergy into his apartment, and made a long discourse to them, to prove that the reigning pope Innocent IV. was Antichrist. With this exertion his strength was so much exhausted, that he expired soon after, Oct. 9, 1253. A contemporary historian says, "He was a free and bold reprimander of the pope and the king; an admonisher of the prelates; a corrector of the monks; an instructor of the clergy; a supporter of the studious; a censurer of the incontinent; a scourge and terror to the court of Rome; a diligent searcher of the scriptures; and a frequent preacher to the people. At his table he was hospitable, polite, and cheerful. In the church he was contrite, devout, and solemn; and in performing all the duties of his office he was venerable, active, and indefatigable." The illustrious Roger Bacon, who had the best opportunities of forming a true judgement of the extent of his learning, by perusing his works, and by frequently conversing with him, hath given this honourable testimony in his favour. "Robert Grouthead, bishop of Lincoln, and his friend friar Adam de Marisco, are the two most learned men in the world, and excel all the rest of mankind both in divine and human knowledge." This excellent prelate was a very voluminous writer, and composed a prodigious number of treatises on a great variety of subjects in philosophy and divinity, a catalogue of which is given by Bale.

GRUB, in zoology, is the English name of the hexapode worms, produced from the eggs of beetles, &c. and which at length are transformed into winged insects of the same species with their parents.

GRUBSTREET, originally the name of a street near Moorfields in London, much inhabited by writers of small histories, dictionaries, and temporary poems; whence any mean production is called grubstreet.

Χυρῖς Ἰδακκὶ μὲν ἀεθλα, μὲν ἀλγυῖα πικρὰ
Ἀπασίως ἰσὺν ἔδας μαρομήν.

GRUME, [*grumus*, Lat.] in medicine, denotes a concreted clot of blood, milk, or other substance. Hence grumous blood is that which approaches to the nature of grume, and by its viscosity, and stagnating in the capillary vessels, produces several disorders.

GRUND, or **GRUNDE**, a town of Brunswick, in the Hartz Forest, 12 miles S. W. of Goslar.

GRUNINGEN, a town of the Helvetic republic, 12 miles E. of Zurich.

GRUNINGEN, a town in Halberstadt, on the Boden, 15 miles E. of Halberstadt.

GRUPPO, or **TURNED SHAKE**, a musical grace, defined by Playford to consist in the alternate prolotion of two tones in juxtaposition to each other, with a close on the note immediately beneath the lower of them.

GRUS, in antiquity, a dance performed yearly by the young Athenians around the temple of Apollo, on the day of the Delia.

GRUS, in astronomy, a southern constellation, not visible in our latitude. The number of stars in this constellation, according to Mr. Sharp's Catalogue, is 13.

GRUS,

GRUS, in ornithology. See ARDEA.

GRUYERES, GRUYERS, or GRUYIRES, a town, and late county and bailiwick, of the Helvetic republic, in the canton of Friburg, famous for cheese, 15 miles S. of Friburg.

GRY, [γρυ,] any thing of little value; as, the paring of the nails. A measure containing one-tenth of a line. A line is one-tenth of a digit, and a digit one-tenth of a foot, and a philosophical foot one-third of a pendulum, whose diadromes, or vibrations, in the latitude of 45 degrees, are each equal to one second of time, or one-sixtieth of a minute.

GRYLLUS, the LOCUST, GRASSHOPPER, and CRICKET, in entomology, a genus of insects belonging to the order hemiptera. The generic character is, head inflexed, armed with jaws, and furnished with feelers. Antennæ, in most species, either filiform or setaceous. Wings four, deflex, convoluted: lower wings plaited. Hind legs formed for leaping: claws double on all the feet. There are 61 species, of which the following are most worthy of notice:

1. Among the most numerous species is the *GRYLLUS MIGRATORIUS* of Linnæus, or COMMON MIGRATORY LOCUST, which of all the insects capable of injuring mankind seems to possess the most dreadful powers of destruction. Legions of these animals are from time to time observed in various parts of the world, where the havoc they commit is almost incredible: whole provinces are in a manner desolated by them in the space of a few days, and the air is darkened by their numbers: nay, even when dead, they are still terrible; since the putrefaction arising from their inconceivable numbers is such that it has been regarded as one of the probable causes of pestilence in the Eastern regions. This formidable locust is generally of a brownish colour, varied with pale red, or flesh-colour, and the legs are frequently bluish. In the year 1748, it appeared in irregular flights in several parts of Europe, as in Germany, France, and England; and in the capital itself and its neighbourhood great numbers were seen: they perished, however, in a short time, and were happily not productive of any material mischief, having been probably driven by some irregular wind out of their intended course, and weakened by the coolness of our climate. From a paper published in the 18th volume of the Philosophical Transactions we find, that in the year 1693, swarms of this species of locust settled in some parts of Wales. Two vast flights were observed in the air not far from the town of Dolgalken, in Merionethshire: the others fell in Pembrokeshire. From a letter published in the 38th volume of the same work, it appears, that some parts of Germany, particularly in the march of Brandenburg, &c. suffered considerable injury from the depredations of these animals. They made their appearance in the spring of the year 1732, from flights which had deposited their eggs in the ground the preceding year. They attacked and devoured the young spike of the wheat, &c. and this chiefly by night, and thus laid waste many acres at a time beyond all hope of recovery. In the 46th volume of the same Transactions we find a description of the ravages of these animals in Wallachia, Moldavia, Transylvania, Hungary, and Poland, in the years 1747 and 1748. They multiply more speedily than any animal in the creation, but are chiefly to be dreaded in the countries where they breed; being unable to live in cold climates. If, however, at any future period, they should again invade this island, it will be advisable to burn, previously to their approach, such combustibles as emit a thick and offensive smoke; for instance, turf, wet straw, &c. sprinkled with sulphur. An instance occurred many years since, in Germany, where a swarm of locusts was driven from one district to another, by the noise of bells, spades, hammers, and other metallic instruments. The ravages of locusts in various parts of the world, at different periods, are recorded by numerous authors. In the year 593 of the Christian æra, after a great drought, these animals appeared in such vast legions as to cause a famine in many countries. In 677 Syria and Mesopotamia were over-run by them. In 852, immense swarms took their flight from the Eastern regions into the West, flying with such a sound that they might have been mistaken for birds: they destroyed all vegetables, not sparing even the bark of trees and the thatch of houses; and devoured the corn so rapidly, as to destroy, on computation, a hundred and forty acres in a day: their daily marches or distances of flight were computed at twenty miles; and these were regulated by leaders or kings, who flew first, and settled on the

spot which was to be visited at the same hour the next day by the whole legion: these marches were always undertaken at sunrise. These locusts were at length driven by the force of the winds into the Belgic ocean, and being thrown back by the tide and left on the shores, caused a dreadful pestilence by their smell. In 1271, all the corn-fields of Milan were destroyed; and in the year 1339 all those of Lombardy. In 1541, incredible hosts afflicted Poland, Wallachia, and all the adjoining territories, darkening the sun with their numbers, and ravaging all the fruits of the earth.

2. *G. CRISTATUS* is one of the largest species of locust yet known, being five or six times the size of the *gryllus migratorius*, and, together with some others of the larger kind, is made use of in some parts of the world as an article of food: they are eaten both fresh and salted, in which last state they are publicly sold in the markets of some parts of the Levant. The quantity of edible substance which they afford is but small, especially in the male insects; but the females, on account of the ovaries, afford a more nutritious sustenance. The *gryllus cristatus* is a highly beautiful animal; being of a bright red, with the body annulated with black; and the legs varied with yellow: the upper wings tessellated with alternate variegations of dark and pale green; the lower with transverse undulated streaks: the length of the animal from head to tail is about four inches, and the expanse of wings from tip to tip, when fully extended, hardly less than seven inches and a half.

3. *G. GRYLLOALPA*, or MOLE-CRICKET, is by far the most curious of this genus; and in its colour and manners differs greatly from the rest. It is of an uncouth, and even formidable aspect, measuring more than two inches in length; and is of a broad and slightly flattened shape, of a dusky brown colour, with a ferruginous cast on the under parts, and is readily distinguished by the extraordinary structure of its fore-legs, which are excessively strong, and furnished with very broad feet, divided into several sharp, claw-shaped, segments, with which it is enabled to burrow under ground in the manner of a mole. The mole-cricket lives entirely on vegetables, devouring the young roots of grasses, corn, and various esculent plants, and commits great devastation in gardens. It is found in most parts of Europe, and in the northern parts of Asia and America. See Plate LXXXVI.

4. The *TETTIGONIA*, or GRASSHOPPER, well known in our meadows, belongs to this genus.

5. The *ACHETA*, or CRICKET, of which there are two varieties, the hearth and the field cricket.

6. The *GRISEUS* is found in Italy. See Plate LXXXVI.

7. The *STRIDULUS* inhabits most parts of Europe. See Plate LXXXVI.

GRYPHITES, or CROW'S STONE, in natural history, an oblong fossile-shell, very narrow at the head, and becoming gradually wider to the extremity, where it ends in a circular limb; the head or beak of this is very hooked, or bent inward. They are frequently found in our gravel or clay-pits in many counties.

GUADALAJARA, or *GUADALAXARA*, a town of Spain, in the province of New Castile, 22 miles N. E. of Madrid.

GUADALAJARA, a province, town, and river, of Mexico.

GUADALAVIAR, a river of Spain, which rises on the confines of Arragon and New Castile, and falls into the Mediterranean sea, a little below Valencia.

GUADALOUPE, a town of Spain, in Estremadura, 45 miles S. W. of Toledo.

GUADALOUPE, a river of Spain, in Estremadura.

GUADALOUPE, one of the Caribbee or Leeward Islands, lying about midway between Antigua and Martinico. It is 45 miles long, 38 broad, and, being of an irregular figure, is about 240 miles in circumference. It is now in possession of the British.

GUADALQUIVER, one of the most famous rivers of Spain, rises in Andalusia, near the confines of Granada, and running quite through Andalusia, by the towns of Baiza, Andaxar, Cordova, and Seville, falls at last into the Bay of Cadiz.

GUADARAMA, a town of Spain, on the above river, 18 miles N. W. of Madrid; famous for cheese.

GUADIANA, a large river of Spain, which rises in New Castile, passes by Calatrava, Medelin, Merida, and Badajox, and falls into the bay of Cadiz.

GUADIX, a town of Spain, in Granada, with a bishop's see.

GUAIAACUM,

GUAIACUM, LIGNUM VITÆ, or POCKWOOD, in botany, a genus of the monogynia order, and decandria class of plants; natural order, Gruinales. Calyx five-cleft, unequal; petals five, inserted into the receptacle; capsule angular, five-celled. There are four species.

G. OFFICINALE, the **COMMON LIGNUM VITÆ** used in medicine, is a native of the West India islands and the warmer parts of America. There it becomes a large tree, having a hard, brittle, brownish bark, not very thick. The wood is firm, solid, ponderous, very resinous, of a blackish yellow colour in the middle, and of a hot aromatic taste. See Plate LXV. From this species is obtained a resin which exudes spontaneously, and is also driven out artificially by means of heat. This substance has been long known and celebrated as a medicine in various cases; and in the Transactions of the Royal Society for the year 1806, we have a very complete analysis of it: by distillation 100 parts yielded

Acidulous water	5.5
Thick brown oil	24.5
Thin empyreumatic oil	29.0
Charcoal	30.5
Gases consisting of carbonic acid and } carbureted hydrogen	10.5
	100.0

GUALEOR, GUALIOR, or GOWALIER, a province of Asia, situated in the middle of Hindostan.

GUALEOR, or GUALIOR, a large town of the above province, with a celebrated fortress of great strength. It is 8 miles from Reypour, and 80 S. of Agra.

GUALTEIRI, or GUALTERO, a town of the late Cisalpine republic, in the department of Crostolo, and late duchy of Reggio, 13 miles N. of Reggio.

GUAM, or GUAHAN, the largest of the Ladrone islands. It is about 120 miles in circumference; and is the only one among the innumerable islands in the South Sea, which has a town built in the European style, with a regular fort, a church, and civilized inhabitants. See **LADRONE**.

GUAMANCA, or GUAMANGA, a province of Peru, which begins 240 miles E. of Lima, and extends along the centre of the Cordilleras. The air is temperate; the soil fertile; and the mines abound with gold, silver, copper, lead, iron, quicksilver, loadstone, and sulphur.

GUAMANGA, the capital of the above province.

GUANZAVELICA, a town of South America in Peru, and in the audience of Lima. It abounds in mines of quicksilver. Lou. 71. 59. W. Lat. 12. 40. S.

GUARANTEE, or WARRANTEE, in law, a term signifying him whom the warranter undertakes to indemnify or secure from damage.

GUARANTEE, or GUARANTY, in matters of polity, the engagement of neutral states, whereby they plight their faith that certain treaties shall be inviolably observed, or that they will make war against the aggressor.

GUARD, in a general sense, signifies the defence or preservation of any thing; the act of observing what passes, to prevent surprise; or the care used to prevent any thing from happening contrary to our intentions or inclinations.

GUARD, in fencing, a posture proper to defend the body from the sword of the antagonist.

GUARD, in the military art, is a duty performed by a body of men, to secure an army or place from being surprised by an enemy. In garrison the guards are relieved every day: hence every soldier mounts guard once every day in time of peace, and much oftener in time of war. See **HONOURS**.

GUARD, ADVANCED, or VAN-GUARD. See **ADVANCE-GUARD**.

GUARD, ARTILLERY. See **ARTILLERY**.

GUARD, ARTILLERY QUARTER, is frequently a non-commissioned officer's guard from the royal regiment of artillery, whose corps de garde is always in the front of their incampment.

GUARD, ARTILLERY REAR, consists in a corporal and six men, posted in the rear of the park.

GUARD, BAGGAGE, is always an officer's guard, who has the care of the baggage on a march. The waggons should be num-

bered by companies, and follow one another regularly: vigilance and attention in the passage of hollow-ways, woods, and thickets, must be strictly observed by this guard.

GUARD, FORAGE, a detachment sent out to secure the foragers, and who are posted at all places, where either the enemy's party may come to disturb the foragers, or where they may spread too near the enemy, so as to be in danger of being taken. It consists both of horse and foot, who must remain on their posts till the foragers are all come off the ground.

GUARD, GRAND, three or four squadrons of horse, commanded by a field-officer, posted at about a mile or a mile and a half from the camp, on the right and left wings, towards the enemy, for the better security of the camp.

GUARD, MAIN, is that from which all other guards are detached. Those who are mounting guard assemble at their respective captain's quarters, and march from thence to the parade in good order; where, after the whole guard is drawn up, the small guards are detached to their respective posts: then the subalterns throw lots for their guards, who are all under the command of the captain of the main-guard. This guard mounts in garrison at different hours, as the governor pleases.

GUARD, PIQUET, a number of horse and foot, always in readiness in case of an alarm: the horses are generally saddled, and the riders booted. The foot drawn up at the head of the battalion, frequently at the beating of the tat-too; but afterwards return to their tents, where they hold themselves in readiness to march. This guard is to resist in case of an attack, until the army gets ready.

GUARD, PROVOST, is always an officer's guard that attends the provost in his rounds, either to prevent dissention, or marauding, rioting, &c. See **PROVOST**.

GUARD, QUARTER, is a small guard commanded by a subaltern officer, posted in the front of each battalion, 222 feet before the front of the regiment.

GUARD, REAR, that part of the army which brings up the rear on a march, generally composed of all the old grand guards of the camp. The rear-guard of a party is often eight or ten horse, about 500 paces behind. Hence the advance-guard going out upon a party, form the rear-guard in their retreat. Rear-guard is also a corporal's guard placed in the rear of a regiment, to keep good order.

GUARD, STANDARD, a small guard under a corporal, out of each regiment of horse, who mount on foot in the front of each regiment, at the distance of 20 feet from the streets, opposite the main street.

GUARD, TRENCH, only mounts in the time of a siege, and sometimes consists of three, four, or six battalions, according to the importance of the siege. This guard must oppose the besieged when they sally out, protect the workmen, &c.

GUARDS also imply the troops kept to guard the king's person, and consist both of horse and foot.

GUARDS, FOOT, are regiments of foot appointed for the guard of his majesty and his palace. There are three regiments of them, numerically titled.

GUARDS, HORSE, in Britain, are gentlemen chosen for their bravery, to be entrusted with the guard of the king's person; and were formerly divided into four troops named numerically.

GUARDS, EXTRAORDINARY, or DETACHMENTS, are only commanded on particular occasions; either for the security of the camp, to cover the foragers, or for convoys, escorts, or expeditions.

GUARDA, or GUARDIA, a strong city of Portugal, in the province of Beira, 18 miles S. W. of Almeida.

GUARDAMAR, a sea-port town of Spain, in Valencia, on the Segura, 17 miles S. S. W. of Alicante.

GUARD-BOAT, a boat appointed to row the rounds amongst the ships of war which are laid up in any harbour, &c. to observe that their officers keep a good looking-out, calling to the guard-boat as she passes, and not suffering her crew to come on board, without having previously communicated the watch-word of the night.

GUARDIA ALFEREZ, a town of Naples, in the province of Molise, 21 miles N. E. of Molise.

GUARDIAN, in law, signifies one who has the custody and education of such persons as have not sufficient discretion to take care

care of themselves and their own affairs, as children and ideots. The guardian's business is to take the profits of the minor's lands to his use, and to account for the same; to sell all moveables within a reasonable time, and to convert them into land or money, unless the minor is near of age, and may want such things himself; and to pay interest for the money in his hands, that might have been so placed out; in which case it will be presumed that the guardian made use of it himself. He is to sustain the lands of the heir, without making destruction of any thing thereon, and to keep it safely for him: if he commit waste on the lands, it is a forfeiture of the guardianship: 3 Edward I. And where persons, as guardians, hold over any land, without the consent of the person who is next entitled, they shall be adjudged trespassers, and shall be accountable; 6 Ann. cap. xviii.

GUARDIAN OF THE SPIRITUALITIES, he to whom the spiritual jurisdiction of any diocese is committed, during the vacancy of the see. He may be either guardian in law, or jure magistratus, as the archbishop is of any diocese within his province; or guardian by delegation, as he whom the archbishop or vicar-general doth for the time depute.

GUARDIARA, a river of Spain which rises in New Castile, runs through the provinces of La Mancha and Estremadura; and falls into the Atlantic between Ayamonte and Castromarin.

GUARD-SHIP, is a vessel of war appointed to superintend the marine in a harbour or river, and to see that the ships which are not commissioned have their proper watchward kept duly, by sending her guard-boats round them every night. She is also to receive seamen who are impressed in the time of war.

GUAREA, in botany, a genus of the monogynia order, and octandria class of plants. Calyx quadrifid; petals four; nectarium cylindric, having the anthers in its mouth; capsule quadrilocular, quadrivalvular; seeds solitary.

GUARGALA, or **GUERGUELA**, a town of Africa, and capital of a small kingdom of the same name, in Biledulgerid, S. of Mount Atlas. Lon. 9. 55. E. Lat. 28. 0. N.

GUARMA, or **GUARMOY**, a sea-port of Peru, with a good harbour, about 130 miles N. W. of Lima. Lon. 77. 49. W. Lat. 10. 10. S.

GUASTALLA, or **GUASTELLA**, a strong town of the late Cisalpine republic, in the department of Mincio, and late duchy of Mantua, 15 miles N. of Reggio.

GUATIMALA, an audience of North America, in New Spain, above 750 miles in length, and 450 in breadth. It abounds in chocolate, which they use instead of money.

GUATIMALA, a province of New Spain, in the above audience.

GUATIMALA, or **ST. JAGO DE GUATIMALA**, a large and rich town of New Spain; capital of the above audience and province.

GUAXACA, a province of North America, in New Spain, which is very fertile in wheat, Indian corn, cochineal, and cassia. It is bounded by the gulph of Mexico on the N. and by the South Sea on the S. It contains mines of gold, silver, and crystal.

GUAXACA, the capital of the above province.

GUBBIO, **GUBIO**, or **EUGUBIO**, a town of Italy, in the duchy of Urbino. Lon. 12. 41. E. Lat. 43. 18. N.

GUBEN, in Lower Lusatia, 62 miles north-east of Dresden.

GUDGEON, in ichthyology, a species of cyprinus. See **CYPRINUS**.

GUDGEON, SEA. See **GOBIOUS**.

GUELDERLAND, a late duchy of Europe, bounded on the N. by Overysse and the Zuyder Zee; E. by the bishopric of Munster and the duchy of Cleves; S. by those of Juliers and Brabant, and W. by the States of Utrecht and Holland. It is now annexed to France.

GUELDERLAND, one of the late United Provinces, which now forms the department of the Rhine in Batavia. Its greatest extent from N. to S. is about forty-seven miles, and from W. to E. near as much; but its figure is very irregular. The air here is much healthier and clearer than in the maritime provinces, the land lying higher.

GUELDRES, a town of France, in the department of the Roer, and late duchy of Prussian Guelderland, ten miles N. W. of Venlo, and seventy-two S. E. of Amsterdam.

GUELPHS, or **GUELFS**, a celebrated faction in Italy, antagonists of the Gibelins. The Guelphs and Gibelins filled Italy with blood and carnage for many years. The Guelphs stood for the Pope, against the emperor.

GUERET, a town of France, capital of the department of Creuse, thirty-five miles N. E. of Limoges and 170 S. of Paris.

GUERICKE, **OTTO**, or **ORHO**, a very eminent German philosopher in the seventeenth century, who, with Torricelli, Pascal, and Boyle, greatly contributed to explain the various properties of the air and their effects, was born in the year 1602. He was counsellor to the Elector of Brandenburg; and burgomaster, or consul, of Magdeburg. To him is to be attributed the invention of the air-pump, for though Mr. Boyle had, about the same time, made some approaches towards a similar discovery, yet he ingenuously acknowledged in a letter to his nephew, Lord Dungarvon, that the information which he received from Schottus's "*Mechanica Hydraulico Pneumatica*," published in 1657, in which was an account of Guericke's Experiments, first enabled him to bring his design to any thing like maturity. Guericke was also the inventor of the two brass-hemispheres, to illustrate the pressure of the air, which, being applied to each other, and the air exhausted, resisted the force of sixteen horses to draw them asunder. He likewise invented an instrument to shew the variations in the state of the atmosphere, consisting of a tube, in which was a little image of glass, that descended in rainy or stormy weather, and rose again when the weather became fine and serene. This last machine fell into disuse on the invention of the barometer, and especially after the improvements made in that instrument by Huygens and Amontons. He died in 1686. He was the author of several treatises in natural philosophy, the principal of which is entitled "*Experimenta Magdeburgica*," 1672, folio, and contains his experiments on a vacuum.

GUERNSEY, an island in the British channel, on the coast of the French department of the channel, (late Normandy,) subject to Britain; but, as well as the adjacent islands, governed by its own laws. See **JERSEY**. It extends from E. to W. in the form of a harp, and is thirteen miles from S. W. to N. E. and twelve and a half where broadest, from E. to W. The air is very healthy, and the soil naturally more rich and fertile than that of Jersey; but the inhabitants neglect the cultivation of the land for the sake of commerce.

GUETTARDA, in botany, a genus of the heptandria order, and monœcia class of plants; natural order, *Tricocca*. The male calyx is cylindrical; the corolla cleft into seven parts, and funnel-shaped. The female calyx cylindrical; the corolla cleft into seven parts; one pistil, and the fruit a dry plum. It has four species, natives of the East and West Indies.

GUIANA, a very extensive country of South America, bounded on the E. and N. E. by the Atlantic ocean, and the Oroonoko; on the S. by the Amazon; and on the W. by Grenada and New Andalusia, in Terra Firma, from which it is separated on the W. and N. by the Oroonoko. It extends above 1200 miles in length from N. E. to S. W.; i. e. from the mouth of the Oroonoko to that of the Amazon, and from 300 to 600 in breadth. Most geographers divide it into two parts, calling the country along the coast Carribeano Proper, and the interior Guiana Proper: the last is also styled El Dorado by the Spaniards, on account of the immense quantity of gold it is supposed to contain. The Portuguese, French, and Dutch, have all formed settlements along the coast. The coast between Cape North and Cape Orange is possessed by the natives. Along the coast, the land is low, marshy, and subject to inundations by the rivers which descend from the inland mountains. Hence the atmosphere is suffocating, hot, moist, and unhealthful, especially where the woods have not been cleared away. The Europeans are forced to live in the most disagreeable situations, and fix their colonies at the mouths of the rivers, amidst stinking marshes, and the putrid ooze of salt morasses, for the convenience of exportation and importation. The inhabitants are either natives, who are of a reddish-brown; or negroes and Europeans; or a mixed progeny of these in various combinations.

GUIAQUIL, a city, bay, and harbour, of Peru, capital of an audience of the same name. Lon. 79. 15. W. Lat. 2. 11. S.

GUIDES, in military language, are usually the country people in the neighbourhood of an encampment; who give the army intelligence

telligence concerning the country, the roads by which they are to march, and the probable route of the enemy.

GUIDON, a flag borne by the king's life-guard, broad at one extreme, and almost pointed at the other, and slit or divided into two. It is the ensign or flag of a troop of horse-guards. See **GUARD**.

GUIDON, the officer who bears the guidon, is that in the horse-guards which the ensign is in the foot; and takes place next below the cornet.

GUIDONS, [*guidones*, or *schola guidonum*,] were a company of priests established by Charlemagne, at Rome, to conduct and guide pilgrims to Jerusalem, to visit the holy places: they were also to assist them in case they fell sick, and to perform the last offices to them in case they died.

GUIDORE, a river of Ireland in Donegal.

GUIENNE, a late province of France: it was bounded on the N. by Saintogne, E. by Limosin, and Languedoc; S. by the Pyrenees; and W. by the ocean. It was 225 miles long and 200 broad; and was divided into the Upper and Lower. This extensive province was anciently called Aquitaine, and is now divided into the departments of Aveiron, Dordogne, Gers, Gironde, Landes, Lot, Lot and Garonne, and Lower and Upper Pyrenees. The principal rivers are, the Garonne, the Adour, the Tarn, the Aveiron, and the Lot. Bourdeaux was the capital.

GUILANDINA, the **NICKAR-TREE**: a genus of the monogynia order, and decandria class of plants; natural order, Lomentaceæ. Calyx monophyllous, salver-shaped; petals, inserted into the neck of the calyx, nearly equal; the seed-vessel a legume. There are six species.

GUILD, [from the Saxon verb *gildan*, to pay,] signifies a fraternity or company, because every one was gildare, *i. e.* to pay something towards the charge and support of the company.

GUILD, **GILD**, or **GELD**, is also used among ancient writers, for a compensation or mulct for a fault committed.

GUILD, in the royal boroughs of Scotland, is still used for a company of merchants, who are freemen of the borough.

GUILDFORD, or **GULDEFORD**, a borough-town of Surrey, on the Wye, thirty miles S. W. of London.

GUILDFORD, a town of the United States in Connecticut, twelve miles E. of Newhaven, and 201 N. E. of Philadelphia.

GUILD-HALL, or **GILD-HALL**, the great court of judicature for London. In it are kept the mayor's-court, the sheriff's-court, the court of hustings, court of conscience, court of common-council, chamberlain's-court, &c. Here also the judges sit upon *nisi prius*, &c.

GUILAIN, a town of France, in the department of Jemappes, and late province of Austrian Hainault; six miles from Mons.

GUILLESTREE, a town of France, in the department of the Upper Alps, nine miles N. N. W. of Embrun.

GUILLOTINE, an engine of decapitation, decreed by the French National Assembly, to be the sole punishment of persons condemned to death, on the 20th of March, 1792; so named from Dr. Guillot, a member of the assembly, who proposed it as an instrument of mercy, by giving the criminal a more expeditious death than any other means can afford. Its effect, it must be allowed, is instantaneous. A minute description of it is unnecessary, as fig. 4, and 5, Plate LXXXV. will convey a sufficient idea of it.

GUIMARAENS, a town of Portugal, in Entre Duero e-Minho, ten miles E. of Braga.

GUINEA, a large tract of country lying on the W. side of the continent of Africa, extends along the coast from 3 to 4000 miles, beginning at the river Senegal, about 17° of lat. N. the nearest part of Guinea to Europe as well as to North America. From that river to the Gambia, and in a S. course to Cape Sierra Leona, is comprehended a coast of about 700 miles; being the same tract for which Queen Elizabeth granted charters to the first traders to that coast. From Sierra Leona, the land of Guinea takes a turn to the E. extending about 1500 miles, including those several divisions called the Grain Coast, the Ivory Coast, the Gold Coast, and the Slave Coast, with the kingdom of Benin. From thence the land runs S. along the coast about 1200 miles, and contains the kingdoms of Congo and Angola. From this to the southmost cape of Africa, called the Cape of Good Hope, the country is settled by Caffres and Hottentots, who have never been concern-

ed in making or selling slaves. As all this country lies between the tropics, the air is excessively hot, especially from the beginning of September to the end of March; which, with the coolness of the nights, the frequent thick, stinking, sulphureous mists, and the periodical rains, when the flat country is overflowed, makes it very unhealthy, especially to Europeans. The natives, however, are little affected with the unwholesome air. According to Barbot, they keep much within doors in tempestuous times; their skins being suppled and pores closed by daily anointing with palm-oil, the weather can make but little impression on them. They generally, therefore, enjoy a good state of health, and are able to procure to themselves a comfortable subsistence, with much less care and toil than is necessary in our more northern climate; which last advantage arises not only from the warmth of the climate, but also from the overflowing of the rivers, whereby the land is regularly moistened and rendered extremely fertile; and being in many places improved by culture, abounds with grain and fruits, cattle, poultry, &c. The earth yields all the year a fresh supply of food: few cloaths are requisite, and little art necessary in making them, or in the construction of their houses, which are very simple, principally calculated to defend them from the tempestuous seasons and wild beasts; a few dry reeds covered with mats serve for their beds. The distempers the Europeans are subject to, on this coast, are fevers, fluxes, and colics, which are occasioned by indifferent water and bad air; their settlements lying near the coast, where the fogs and steams arising from the ooze and salt-marshes, and the stinking fish the natives dry on the beach, corrupt the air, and render it fatal to the foreigners. The most temperate men find it difficult to preserve their health; but many hasten their death by their intemperance, or negligence, exposing themselves to the cold air in the evening, after a very hot day. This sudden change, from one extreme to the other, has often very bad effects in hot climates.

GUINEA, [from *Guinea*, a country in Africa, abounding with gold,] a gold-coin valued at one and twenty shillings. The guinea anciently bore the impression of an elephant. Its value has varied; when first struck it was 20s.; from the scarcity of gold it was afterwards advanced to 21s. 6d. but it is now sunk to 21s. The pound weight troy of gold is cut into 44½ parts; each part makes a guinea.

GUINEA, **NEW**, a long and narrow island of the East Indies, very imperfectly known. It was supposed to be connected with New Holland, until Captain Cook discovered the strait which separates them. New Guinea extends from the equator to 12° lat. S. and from 131° to 150° lon. E. The land is very low, but it is covered with a vast luxuriance of wood and herbage. Cocoa-nut, plantain, and bread fruit-trees, flourish in perfection.

GUINEA-HEN. See **NUMIDA**.

GUINEA-PEPPER. See **CAPSICUM**.

GUINEA-PIG. See **CAVIA**.

GUINGAMP, a town of France, in the department of the North Coasts, 258 miles W. of Paris.

GUIPUSCOA, a province of Spain, bounded on the N. by the Atlantic, E. by France, S. E. by Navarre; S. by Alava, and W. by Biscay; twenty-five miles long, and from fifteen to twenty broad.

GUISE, a town of France, in the department of Aisne, on the Oise, twenty miles N. of Laon.

GUITAR, [*ghitara*, Ital. *guitarre*, Fr.] a stringed instrument of music. The guitar has five double rows of strings; of which those that are brass are in the middle, except it be for the burden, an octave lower than the fourth. It was first used in Spain, where it is still greatly in vogue.

GULA, or **GOLA**, in architecture, a wavy member, the contour of which resembles the letter S, which the Greeks call cymatium, and our architects an ogee. See **ARCHITECTURE**.

GULES, a corruption of the French word *gueules*, which in heraldry signifies red, is represented in engraving by perpendicular lines. It serves to denote martial prowess and hardness: for the ancients used this colour to make themselves terrible to their enemies, to stir up magnanimity, and to prevent the seeing of blood, by the likeness of the colours; for which reason perhaps it is used by the English. This colour is by the generality of the English heralds ranked before azure. But the late French heralds preferred azure.

GULF, a capacious bay between two promontories, sometimes taking the name of a sea, when very extensive; but particularly when it only communicates with the sea by a strait. Such are the Euxine or Black Sea, called the Gulf of Constantinople; the Adriatic Sea, or the Gulf of Venice; the Gulf of Lyons, near France, and the Gulf of Sierra near Barbary. All these are in the Mediterranean. There are the Gulfs of Mexico, St. Lawrence, and California, in North America; the Gulf of Persia, or the Red Sea, between Persia and Arabia; the Gulf of Bengal in India; and the Gulfs of Cochin-china and Kamtschatka, near these countries.

GULL, in ichthyology. See **LARUS**.

GULL ISLE, an isle near Cape St. John.

GULLET. See **ANATOMY**.

GUM, [*gummi*, Latin,] a thick, transparent, tasteless fluid, which sometimes exudes from certain species of trees. It is very adhesive, and gradually hardens without losing its transparency; but easily softens again when moistened with water. The gum most commonly used is that which exudes from different species of the mimosa, particularly the nilotica. It is known by the name of gum-arabic. Gum likewise exudes abundantly from the prunus avium, or common wild cherry-tree of this country. Gum is usually obtained in small pieces like tears, moderately hard, and somewhat brittle while cold, so that it can be reduced by pounding to a fine powder. When pure it is colourless, but has usually a yellowish tinge, and it is not destitute of lustre. It has no smell. Its taste is insipid. Its specific gravity varies from 1.31 to 1.48. Gum undergoes no change from being exposed to the atmosphere; but the light of the sun makes it assume a white colour. Water dissolves it in large quantities. The solution, which is known by the name of mucilage, is thick and adhesive: it is often used as a paste, and gives stiffness and lustre to linen. When spread out thin it soon dries, and has the appearance of a varnish; but it readily attracts moisture, and becomes glutinous. Water washes it away entirely. When mucilage is evaporated the gum is obtained unaltered. This mucilaginous solution may be kept for years without undergoing putrefaction. Scarcely any vegetable substance is less liable to decomposition. At last, however, the odour of acetic acid becomes perceptible in it. When gum is exposed to heat it softens and swells, but does not melt; it emits air-bubbles, blackens, and at last, when nearly reduced to charcoal, emits a low blue flame. This flame appears sooner if a flaming substance is held just above the gum. After the gum is consumed, there remains a small quantity of white ashes, composed chiefly of the carbonates of lime and potass. It does not appear that gum is acted upon by oxygen gas. A solution of gum and water, when exposed to the air, soon becomes mouldy on the surface, but undergoes no farther change for a long time. The action of the simple combustibles on gum has scarcely been examined. Azotic gas seems to have no action on it whatever. Gum does not act upon metals; but it has the property of combining with several of the metallic oxides, and forming compounds; at least, some of the salts occasion precipitates when dropped into solutions of gum. The most curious effect is that produced by the oxy muriate of iron. When this salt, concentrated, is dropt into a very strong mucilage, the whole becomes a brown semitransparent jelly, which is not readily dissolved by water. When dried, the jelly becomes lighter coloured, and assumes nearly the appearance of gum. Its taste is that of gum mixed with iron. The species of gum at present known amount to four; though it is likely that a more rigid examination of the vegetable kingdom will discover a greater number. These are gum-arabic, gum-tragacanth, cherry-tree gum, and the mucilage which is contained in the roots and leaves of many plants.

GUM RESINS, are certain substances that have long been used in medicine. They are solid, generally brittle and opaque, have a strong smell, and a pungent and bitter taste. They consist chiefly of gum and resin, the proportions varying with the particular substance. They are never obtained by means of spontaneous exudation, but are procured by wounding the plants which contain them. The principal of the gum-resins are, 1. **AMMONIAC**; 2. **ASSAFETIDA**; 3. **EUPHORBBIUM**; 4. **GALBANUM**; 5. **GAMBOGE**; 6. **MYRRH**; 7. **OPOPONAX**; 8. **SAPAGENUM**. See those articles.

GUN, [perhaps from *canne*, the original of cannon,] a weapon of

offence, which forcibly discharges a ball, or other hard solid matter, through a cylindric tube, by means of inflamed gunpowder. See **GUNPOWDER**. The word gun now includes most species of firearms; pistols and mortars being almost the only ones excepted from this denomination. They are divided into great and small guns: the former including all that we also call cannon, ordnance, or artillery; the latter including **MUSQUETS**, **CARABINES**, **MUSQUETOONS**, **BLUNDERBUSSSES**, **FOWLING-PIECES**, &c. See these articles. It is not known when these weapons were first invented. Though, comparatively speaking, the introduction of guns into the western part of the world is but of a modern date; yet it is certain that in some parts of Asia they have been used, though in a very rude and imperfect manner, for many ages. Philostratus mentions a city near the Hyphasis in the Indies, which was said to be impregnable, and that its inhabitants were relations of the gods, because they threw thunder and lightning upon their enemies. Hence some imagine that guns were used by the eastern nations even in the time of Alexander the Great; but however this may be, many of our modern travellers assert, that they were used in China as far back as A.D. 85, and have continued in use ever since. The first hint of the invention of guns in Europe is in the works of Roger Bacon, who flourished in the thirteenth century. In a treatise written by him about 1280, he proposes to apply the violent explosive force of gunpowder for the destruction of armies. See **GUNPOWDER**, and **PROJECTILES**. Great Guns, or cannon, were formerly dignified with uncommon names. In 1503, Lewis XII. had twelve brass-cannon cast, of an extraordinary size, called after the names of the twelve peers of France. The Spanish and Portuguese called them after their saints. The emperor Charles V. when he marched before Tunis, founded the twelve Apostles. At Milan there is a 70 pounder, called the Pimontelle; and one at Bois-le-duc, called the Devil. A 60 pounder at Dover Castle, called Queen Elizabeth's Pocket-Pistol. An 80 pounder in the Tower of London (many years in Edinburgh Castle,) called Mons Meg. An 80 pounder in the royal arsenal at Berlin, called the Thunderer. An 80 pounder at Malaga, called the Terrible. Two curious 60 pounders in the arsenal at Bremen, called the Messengers of Bad News. And, lastly, an uncommon 70 pounder in the castle of St. Angelo at Rome, made of the nails that fastened the copperplates which covered the ancient Pantheon, with this inscription upon it: "Ex clavis trabalibus porticus Agrippæ." In the beginning of the fifteenth century the following more universal names took place, viz. Cannon royal, or carthoun = 48 pounders, about 90 cwt. Bastard cannon, or $\frac{3}{4}$ carthoun = 36 pounders, 79 cwt. $\frac{1}{2}$ Carthoun = 24 pounders, 60 cwt. Whole culverins = 18 pounders, 50 cwt. Demi-culverins = 9 pounders, 30 cwt. Falcon = 6 pounders, 25 cwt. Sacker = 5, 6, and 8 pounders, 13, 15, and 18 cwt. Basilisk = 48 pounders, 85 cwt. Serpentine = 4 pounders, 8 cwt. Aspik = 2 pounders, 7 cwt. Dragon = 6 pounders, 12 cwt. Syjen = 60 pounders, 81 cwt. Falconet = 3, 2, 1 pounders, 15, 10, and 5 cwt. Moyens, which carried a ball of ten or twelve ounces, &c. Rabinet, which carried a ball of sixteen ounces. At present cannon take their names from the weight of the ball they discharge. Thus a piece that discharges a ball of 24 pounds is called a 24 pounder; one that carries a ball of 12 pounds is called a 12 pounder, and so of the rest, divided into the following sorts, viz. ship-guns, consisting of 42, 36, 32, 24, 18, 12, 9, 6, and 3 pounders. Garrison-guns, in 42, 32, 24, 18, 12, 9, and 6 pounders. Battering guns, in 24, 18, and 12 pounders. Field-pieces, in 12, 9, 6, 3, 2, $1\frac{1}{2}$, 1, and $\frac{3}{4}$ pounders.

GUNDELFINGEN, a town of Bavaria in Neuburgh, on the Brentz, 19 miles N.E. of Ulm, and 38 W. of Neuburg.

GUNDELIA, in botany, a genus of the polygama segregata order, syngenesia class of plants; natural order Compositæ. Calyx scarcely any, five-flowered; corolla tubular, male and hermaphrodite; receptacle chaffy; down none. There is but one species, viz.

G. TOURNEFORTII, a milky plant, with alternate prickly leaves; a native of the Levant.

GUNNER, an officer appointed to fire the guns, either by sea or land. In the Tower of London, and other garrisons, as well as in the field, this officer carries a field-staff, and a large powder-horn in a string over his left shoulder. He marches by the guns; and when there is any apprehension of danger, his field-staff is armed

armed with match. His business is to lay the gun, to pass, and to help to load and traverse her.

GUNNER, MASTER, a patent-officer of the ordnance, who is appointed to teach all such as learn the art of gunnery, and to certify to the master-general the ability of any person recommended to be one of the king's gunners. To every scholar he administers an oath not to serve, without leave, any other prince or state; or teach any one the art of gunnery but such as have taken the said oath.

GUNNERA, in botany, a genus of the diandria order, and gynandria class of plants. The amentum consists of uniflorous scales; there is neither calyx nor corolla; the germen is bidentated with two styles and one seed. It has but one species.

GUNNERY is the art of charging, directing, and exploding, fire-arms, as cannons, mortars, muskets, &c. to the best advantage; and of determining the course, velocity, time of flight, momentum, &c. of the projected body. This branch of science belongs to the subject of **PROJECTILES**, since it treats of projected bodies, and the means of projecting them; we shall therefore refer the reader to that article.

GUNPOWDER, a composition of nitre, sulphur, and charcoal, mixed together, and usually granulated. This easily takes fire, and when fired it rarefies or expands with great vehemence, by means of its elastic force. It is to this powder that we owe all the effect and action of guns, and ordnance of all sorts, so that fortification, with the modern military art, &c. in a great measure depends upon it. The invention of gunpowder is ascribed by Polydore Virgil to a chemist, who having accidentally put some of his composition in a mortar, and covered it with a stone, it happened to take fire, and blew up the stone. Thevet says, that the person here spoken of was a monk of Fribourg, named Constantine Anelzen; but Belleforet, and other authors, with more probability, hold it to be Bartholdus Schwartz, or the black, who discovered it, as some say, about the year 1320. The name mortars, given to a species of ancient artillery, and their application in throwing stone-bullets, strongly favours this account of the discovery, of at least the application of gunpowder. But it appears that Roger Bacon knew of gunpowder near one hundred years before Schwartz was born; and M. Dutens carries the antiquity of gunpowder still much higher, and refers to the writings of the ancients themselves for the proof of it. It appears too, from many authors and many circumstances, that this composition has been known to the Chinese and Indians for thousands of years. The modern proportion of the ingredients for gunpowder is six parts of nitre to one of each of the other two: though Mr. Napier says, he finds the strength commonly to be the greatest when the proportions are, nitre three pounds, charcoal about nine ounces, and sulphur about three ounces. See his paper on gunpowder in the Transactions of the Royal Irish Academy, vol. ii. The cannon-powder was in meal, and the musket-powder grained; and it is certain, that the graining of powder, which is a very considerable advantage, is a modern improvement. To make gunpowder due regard is to be had to the purity or goodness of the ingredients, as well as the proportions of them, for the strength of the powder depends much on that circumstance, and also on the due working or mixing of them together. After the materials have been reduced to fine dust, they are mixed together, and moistened with water, or vinegar, or urine, or spirit of wine, &c. and then beaten together for twenty-four hours, either by hand or by mills, and afterwards pressed into a hard, firm, solid, cake. When dry, it is grained or corned, which is done by breaking the cake of powder into small pieces, and so running it through a sieve; by which means the grains may have any size given them, according to the nature of the sieve employed, either finer or coarser; and thus also the dust is separated from the grains, and again mixed with other manufacturing powder, or worked up into cakes again. Powder is smoothed or glazed, as it is called, for small arms, by the following operation: a hollow cylinder or cask is mounted on an axis, turned by a wheel; this cask is half filled with powder, and turned for six hours, and thus by the mutual friction of the grains of powder it is smoothed or glazed. The fine mealy part, thus separated or worn off from the rest, is again granulated. The velocity of expansion of the flame of gunpowder, when fired in a piece of artillery, without either bullet or other body before it, is prodigiously great, viz. seven thousand feet per second, or upwards, as appears from

the experiments of Mr. Robins. But M. Bernoulli and M. Euler suspect it is still much greater; and Dr. Hutton supposes it may not be less, at the moment of explosion, than four times as much. It is this prodigious celerity of expansion of the flame of gunpowder which is its peculiar excellence, and the circumstance in which it so eminently surpasses all other inventions, either ancient or modern; for as to the momentum of these projectiles only, many of the warlike machines of the ancients produced this in a degree far surpassing that of our heaviest cannon-shot or shells; but the great celerity given to these bodies cannot be in the least approached by any other means but the flame of powder.

GUNPOWDER, METHOD OF RECOVERING DAMAGED. The powder-merchants put part of the powder on a sail-cloth, to which they add an equal weight of what is really good; and with a shovel mingle it well together, dry it in the sun, and barrel it up, keeping it in a dry and proper place. Others again, if it be very bad, restore it by moistening it with vinegar, water, urine, or brandy; then they beat it fine, searce it, and to every pound of powder add 1oz. 1½ or 2oz. according as it is decayed, of melted salt-petre. Afterwards, these ingredients are to be moistened and mixed well, so that nothing can be discerned in the composition, which may be known by cutting the mass; and then granulated as at first. If the powder be in a manner quite spoiled, the only way is to extract the salt-petre with water by boiling, filtrating, evaporating, and crystallizing; and then with fresh sulphur and charcoal to make it up anew.

GUNPOWDER, METHODS OF TRYING. There are two general methods of examining gunpowder; 1st, with regard to its purity: 2d, As to its strength. 1. Its purity is known by laying two or three little heaps near each other upon white paper, and firing one of them. For if this takes fire readily, and the smoke rises upright, without leaving any dross or feculent matter behind, and without burning the paper, or firing the other heaps, it is esteemed a sign that the sulphur and nitre were well purified, that the coal was good, and that the three ingredients were thoroughly incorporated together: but if the other heaps also take fire at the same time, it is presumed that either common salt was mixed with the nitre, or that the coal was not well ground, or the whole mass not well beat and mixed together; and if either the nitre or sulphur be not well purified, the paper will be black or spotted. 2. Several instruments have been invented to try the strength of gunpowder; but they have generally been complained of as inaccurate. Count Rumford in the Philosoph. Trans. Vol. 71, gives an account of an exact method of trying the strength of it. "As the force of the powder (says he) arises from the action of an elastic fluid that is generated from it in its inflammation, the quicker the charge takes fire, the more of this fluid will be generated in any given short space of time, and the greater of course will its effect be upon the bullet. But in the common method of proving gunpowder, the weight by which the powder is confined is so great in proportion to the quantity of the charge, that there is time quite sufficient for the charge to be all inflamed, even when the powder is of the slowest composition, before the body to be put in motion can be sensibly removed from its place. The experiment therefore may shew which of the two kinds of powder is the strongest, when equal quantities of both are confined in equal spaces, and both completely inflamed; but the degree of inflammability, which is a property essential to the goodness of the powder, cannot by these means be ascertained. Hence it appears how powder may answer to the proof, such as is commonly required, and may nevertheless turn out very indifferent when it comes to be used in service. But though the common powder-tries, may shew powder to be better than it really is, they can never make it appear to be worse than it is; it will therefore always be the interest of those who manufacture the commodity to adhere to the old method of proof, but the purchaser will find his account in having it examined in a method by which its goodness may be ascertained with greater precision." To determine the goodness of powder by Count Rumford's method, it is necessary to have a barrel suspended by two iron-rods, that it can easily move backward or forward by the vibration of the rods; and the space it moves through ascertained by marking it on a piece of ribbon. The barrel being then charged with powder, and fitted with a proper bullet, is to be fired, and the recoil marked upon the ribbon. The experiment is to be repeated three or four times, or oftener if there is any difference in the recoil; the extremes

extremes of which may be marked with black lines on the ribbon, and the word *proof* written in the middle-line betwixt the two. But if the experiments are made with sufficient accuracy, there will commonly be very little difference in the length to which the ribbon is drawn out. Thus the comparative goodness of powder may easily be ascertained; for the stronger the powder is, the greater will be the recoil, and consequently the greater length to which the ribbon will be drawn out: and if care is taken in proportioning the charge to the weight of the bullet, to come as near as possible to the medium proportion that obtains in practice, the determination of the goodness of gunpowder from the result of this experiment cannot fail to hold good in actual service. That which is found to answer best is a small cannon, the bore of which is about one inch in diameter, and it is usually charged with two ounces of powder, and with powder only, as a ball is not necessary, and the strength of the powder is accurately shown by the arc of the gun's recoil.

GUNPOWDER, STATUTES RESPECTING. No person shall make gunpowder, but in the regular manufactories established at the time of making the statute 12 George III. c. 61, or licensed by the sessions, pursuant to certain provisions, under forfeiture of the gunpowder, and two shillings per pound; nor are pestle-mills to be used under a similar penalty. Only forty pounds of powder is to be made at one time under one pair of stones, except Battle-powder, made at Battle and elsewhere in Sussex. Not more than forty hundred weight to be dried at one time in one stove; and the quantity only required for immediate use to be kept in or near the place of making, except in brick or stone magazines, fifty yards at least from the mill. Not more than twenty-five barrels to be carried in any land-carriage, nor more than two hundred barrels by water, unless going by sea or coastwise, each barrel not to contain more than one hundred pounds. No dealer to keep more than two hundred pounds of powder, nor any person not a dealer, more than fifty pound in the cities of London and Westminster, or within three miles thereof, or within any other city, borough, or market-town, or one mile thereof, or within two miles of the king's palaces, or magazines, or half a mile of any parish-church; on pain of forfeiture, and two shillings per pound, except in licensed mills, or to the amount of three hundred pounds for the use of collieries, within two hundred yards of them.

GUNTER, EDMUND, M. A. and B. D. an excellent mathematician, born in Hertfordshire in 1581. He studied at Westminster and Oxford, where he graduated in 1606, and 1615. Being eminent for his knowledge in the mathematics, he was in 1613, chosen professor of astronomy in Gresham-college, where he distinguished himself by his lectures and writings. He improved the trigonometrical tables then in use, by adapting them to the solution of spherical triangles without the aid of secants. In 1622 he made the important discovery that the variation of the needle varies. Soon after he invented the rule for working questions in proportion instrumentally, which is an easy and excellent method of combining arithmetic and geometry, adapted to the understanding of persons of the most ordinary capacities. The lines on which the operation is performed, is called Gunter's line. He also invented a quadrant, and greatly improved the sector and other instruments. We are indebted to him for many other inventions and improvements, most of which are printed in his works. He died at Gresham-college in 1626. His first publication was entitled "Canon Triangulorum." His works have been collected, and various editions of them have been published. The fifth is by William Leybourn, in 1673, 4th., containing the description and use of the sector, cross-staff, bow, quadrant, and other instruments; with several pieces added by Samuel Foster, Henry Bond, and William Leybourn.

GUNTER'S CHAIN, the chain in common use for measuring land, according to true or statute measure; so called from Mr. Gunter, its reputed inventor. The length of the chain is 66 feet, or 22 yards, or four poles, of $5\frac{1}{2}$ yards each; and it is divided into 100 links, of 7.92 inches each. This chain is the most convenient of any thing for measuring land, because the contents thence computed are so easily turned into acres. The reason of which is, that an acre of land is just equal to 10 square chains, or 10 chains in length and one in breadth, or equal to 100,000 square links. Hence, the dimensions being taken in chains, and multiplied together, it gives the content in square chains, which therefore being

divided by 10, or a figure cut off for decimals, brings the content to acres; after which the decimals are reduced to roods and perches, by multiplying by 4 and 40. But a better way is to set the dimensions down in links, as integers, considering each chain as 100 links; then, having found the content in square links, divide these by 100,000, that is, cut off five places for decimals, the rest are acres, and the decimals are reduced to roods and perches as before. Suppose a rectangular field to be measured be 624 links in length, and 550 in breadth, to find its area we say

624
550
31200
3120

29.12

The area, or quantity of surface, is 3 A. 1 R. 29P.

GUNTER'S LINE, a logarithmic line, usually graduated upon scales, sectors, &c. It is also called the line of lines, and line of numbers; being only the logarithms graduated upon a ruler, which therefore serves to solve problems instrumentally in the same manner as logarithms do arithmetically. It is usually divided into an hundred parts, every tenth whereof is numbered, beginning with 1, and ending with 10; so that if the first great division, marked 1, stand for one-tenth of any integer, the next division, marked 2, will stand for two-tenths; 3, three-tenths, and so on; and the intermediate divisions will, in like manner, represent 100th parts of the same integer. If each of the great divisions represent 10 integers, then will the less divisions stand for integers; and if the great divisions be supposed each 100, the subdivisions will be each 10.

GUNTER'S LINE, USE OF. 1. To find the product of two numbers. From 1. extend the compasses to the multiplier; and the same extent, applied the same way from the multiplicand, will reach to the product. Thus, if the product of 4 and 8 be required, extend the compasses from 1 to 4, and that extent laid from 8 the same way, will reach to 32, their product. 2. To divide one number by another. The extent from the divisor to unity will reach from the dividend to the quotient: thus to divide 36 by 4, extend the compasses from 4 to 1, and the same extent will reach from 36 to 9, the quotient sought. 3. To three given numbers, to find a 4th proportional. Suppose the numbers 6, 8, 9; extend the compasses from 6 to 8, and this extent, laid from 9 the same way, will reach to 12, the fourth proportional required. 4. To find a mean proportional between any two given numbers. Suppose 8 and 32: extend the compasses from 8 in the left hand part of the line to 32 in the right; then bisecting this distance, its half will reach from 8 forward, or from 32 backward, to 16, the mean proportional sought. 5. To extract the square root of any number. Suppose 25: bisect the distance between one on the scale and the point representing 25; then the half of this distance, set off from 1, will give the point representing the root 5. In the same manner the cube root, or that of any higher power, may be found by dividing the distance on the line, between 1 and the given number, into as many equal parts as the index of the power expresses; then one of those parts, set from 1, will find the point representing the root required.

GUNTER'S QUADRANT, one made of wood, brass, &c. containing a kind of stereographic projection of the sphere, on the plane of the equinoctial; the eye being supposed placed in one of the poles. See QUADRANT.

GUNTER'S SCALE, usually called by seamen the Gunter, is a large plain scale, having various lines upon it, of great use in working the cases or questions in navigation. This scale is usually two feet long, and about an inch and a half broad, with various lines upon it, both natural and logarithmic, relating to trigonometry, navigation, &c. On the one side are the natural lines, and on the other the artificial or logarithmic ones. The former side is first divided into inches and tenths, and numbered from one to twenty-

four inches, running the whole length near one edge. One half the length of this side consists of two plain diagonal-scales, for taking off dimensions to three places of figures. On the other half or foot of this side, are contained various lines relating to trigonometry, in the natural numbers, and marked thus, viz.

Rumb, the rumb or points of the compass;

Chord, the line of chords;

Sine, the line of sines;

Tang, the tangents;

S. T. the semi-tangents; and at the other end of this half are,

Leag. leagues, or equal parts;

Rumb, another line of rumb;

M. L. miles of longitude;

Chor. another line of chords.

Also in the middle of this foot are L, and P, two other lines of equal parts: and all these lines on this side of the scale serve for drawing or laying down the figures to the cases in trigonometry and navigation. On the other side of the scale, are the following artificial or logarithmic lines, which serve for working or resolving those cases; viz.

S. R. the sine-rumbs;

T. R. the tangent-rumbs;

Numb. line of numbers;

Sine, sines;

V. S. the versed sines;

Tang. the tangents;

Mer. Meridional parts;

E. P. Equal parts.

GUNTOOR, a circar of Hindostan, N. of the Carnatic, and S. of the Kistnah, extending 40 miles along the bay of Bengal. It belongs to Britain.

GUNWALE, or **GUNNEL OF A SHIP**. That piece of timber which reaches on either side of the ship from the half-deck to the fore-castle, being the uppermost bend which finishes the up-works of the hull in that part, and wherein they put the stanchions which support the waste trees; and this is called the gunwale, whether there be guns in the ship or no; and the lower part of any port, where any ordnance are, is also termed the gunwale.

GURNARD. See **TRIGLA**.

GURRAH MONDELLA, a circar of Hindostan, between Allahabad and Berar; 120 miles long, and from 40 to 80 broad.

GURRAH, the capital of the above.

GUSSAGO, a town and district of the late Cisalpine republic, in the department of the Mela.

GUSSET, in heraldry, is formed by a line drawn from the dexter or sinister chief points, and falling down perpendicularly to the extreme base.

GUSTAVIA, in botany, a genus of the polyandria order, and monadelphia class of plants. Calyx none; petals very numerous; berry multilocular; seeds appendaged. It has only one species, a tree of Surinam and Cayenne.

GUSTAVUS I. king of Sweden, son of Eric Vasa, duke of Gripsholm. Christian II. king of Denmark having made himself master of Sweden, confined Gustavus at Copenhagen; but he making his escape, wandered long in the forests, till the cruelties of the tyrant having occasioned a revolution, he was first declared governor of Sweden, and then, in 1513, elected king. He introduced Lutheranism into his dominions, and died in 1560.

GUSTAVUS ADOLPHUS, THE GREAT, king of Sweden, was born at Stockholm in 1594, and succeeded his father Charles IX. in 1611. He espoused the cause of the Protestants in Germany, who were oppressed by Ferdinand I. He was a great warrior, and gained many victories, but was killed in the battle of Lutzen, where his troops got the victory, and defeated two of the emperor's armies, in Nov. 1632.

GUTTÆ, in architecture, are ornaments in the form of little cones, used in the plafond of the Doric cornice, or on the architrave underneath the triglyphs, representing a sort of drops or bells. They are usually six in number. See **ARCHITECTURE**.

GUTTÆ ANGLICANÆ, ENGLISH DROPS, a chemical preparation esteemed of great virtue against vapours and lethargic affections, and purchased at 5000l. by king Charles II. from the inventor, Dr. Goddard. It is a spirit drawn by the retort from raw milk, and rectified with an essential oil.

GUTTA ROSACEA, in medicine, a red or pimpled face; a

distemper which, though not always owing to hard drinking, is most incident to tipplers.

GUTTA SERENA, a disease in which the patient, without any apparent fault in the eye, is deprived of sight. See **MEDICINE**.

GUTTERS, in architecture, a kind of canals in the roofs of houses, serving to receive and carry off the rain.

GUTTURAL, [*gutturalis*, Latin,] a term applied to letters or sounds pronounced or formed as it were in the throat. There are four guttural letters in the Hebrew, viz. ק, ח, ע, ג, which, for memory's sake, are termed ahachah.

GUTTY, in heraldry, a term used when any thing is charged or sprinkled with drops. In blazoning, the colour of the drops is to be named.

GUY, [from *guide*,] a rope used to lift any thing into the ship.

GUY is also a large slack rope, extending from the head of the main-mast to the head of the fore-mast, and having two or three large blocks fastened to the middle of it; to sustain the tackle used to hoist in and out the cargo of a merchant-ship.

GUZ, an Indian measure, = 1 yard English.

GUZERAT, a peninsula of Hindostan, 170 miles long, and 140 broad, formed by the Arabian sea, and the gulf of Cambay. It was the richest province in the Mogul's empire.

GUZES, in heraldry, roundless of a sanguine or murry colour. These, from their bloody hue, are by some supposed to represent wounds.

GYARUS, one of the Cyclades, E. of Delos, 12 miles in compass. It was a desert island, and allotted for a place of banishment by the Romans.

GYBING, the act of shifting any boom-sail from one side of the mast to the other. By a boom-sail is meant any sail whose bottom is extended by a boom, the fore-end of which is hooked to its respective mast; so as to swing occasionally on either side of the vessel, describing an arch, of which the mast will be the centre. As the wind or the course changes, it becomes necessary to change the position of the boom, with its sail, which is accordingly shifted to the other side of the vessel as a door turns upon its hinges. The boom is pushed out by the effort of the wind upon the sail, and is restrained in a proper situation by a strong tackle communicating with the vessel's stem, called the sheet. It is also confined on the fore-part by the Guy.

GYMNANTHES, in botany, a genus of the monoecia monadelphia class and order. Male ament naked; perianth and corolla none; stamina pedicels three-parted or three-forked, another-bearing; female ament or germ pedicelled; corolla none; style trifid; capsule trilocular, three-celled. It has two species, natives of the West-Indies.

GYMNASIARCHA, in antiquity, the director of the gymnasium. He had two deputies under him; the Xystarcha, and the Gymnastes.

GYMNASIUM, [from *γυμνος*, naked,] in Grecian antiquity, a place fitted for performing the exercises of the body, &c. so called because they put off their clothes, to practise with the more freedom. Gymnasia were first used at Lacedæmon, but were afterwards common in all parts of Greece; and imitated, augmented, and improved, at Rome. There were three principal gymnasia at Athens; the Academy, the Lyceum, and the Cynosarges. Vitruvius describes the structure and form of the ancient gymnasia, lib. v. c. 11. They were called *Palæstræ*, from wrestling, which was one of the most usual exercises; and the Romans also called them *Therma*, because the baths made a principal part of them. They performed these exercises in Homer's time in drawers; which were not laid aside before the 32d Olympiad. One Orsippus is said to have been the first who introduced the practice: for having been worsted by his drawers entangling him, he threw them aside, and the rest afterwards imitated him. The gymnasia were a knot of buildings united, sufficiently capacious to hold many thousands of people at once; and having room for philosophers, rhetoricians, and the professors of all other sciences to read their lectures; and wrestlers, dancers, and all others who had a mind to exercise; at the same time without the least disturbance or interruption. They consisted of 12 parts, viz. 1. The exterior porticos, where the philosophers, rhetoricians, mathematicians, physicians, and other virtuosi, read public lectures, and where they also disputed and rehearsed their performances. 2.

The ephebeum, where the youth assembled very early, to learn their exercises in private without any spectators. 3. The coryceum, apodyterion, or gymnasterion, a kind of wardrobe, where they stripped, either to bathe or exercise. 4. The elæothesium, alipterion, or nuctuarium, appointed for the unctions, which either preceded or followed the use of the bath, wrestling, pancratia, &c. 5. The conisterium or conistra, in which they covered themselves with sand or dust, to dry up the oil or sweat. 6. The palastra, properly so called, where they practised wrestling, the pugillate, pancratia, and other exercises. 7. The sphæristerium or tennis-court, reserved for exercises wherein they used balls. 8. Large unpaved alleys, which comprehended the space between the porticos and the walls wherewith the edifice was surrounded. 9. The xysti or porticos for the wrestlers in winter or bad weather. 10. Other xysti or open alleys, some of which were quite open, and others planted with trees. 11. The baths, consisting of several different apartments. 12. The stadium, a large space of a semicircular form, covered with sand, and surrounded with seats for the spectators. For the administration of the gymnasia, there were different officers: the principal were, 1. The gymnasiarcha. 2. The xystarcha. 3. The gymnastes. And, 4. The pædotriba. See these articles. Under these four officers were a number of subalterns. The gymnastic exercises may be reduced to two general classes; as they depend either on the action of the body alone, or as they require external agents or instruments. The latter consisted chiefly in mounting the horse, driving the chariot, and swimming. The former were chiefly of two kinds; Orchestice, and Palæstrice; which see.

GYMNASTES, a deputy under the gymnasiarch, who was master of the ceremonies.

GYMNASTICS, **GYMNASTICÆ**, or the **GYMNASTIC**, [*γυμναστική*], the art of performing exercises of the body, whether for defence, health, or diversion. See **GYMNASIUM**. Several modern writers have treated of this art. M. Burette has given the history of gymnastics in the Mem. of the R. Acad. of Inscript. On the first establishment of society, men, being apprised of the necessity of military exercises, for repelling the insults of their neighbours, instituted games, and proposed prizes to animate their youth to combats of divers kind. And as running, leaping, throwing the javelin, driving a ball, tossing a quoit, wrestling, &c. were exercises suited to the manner of fighting in those days; so the youth vied to excel in them, in the presence of the aged, who sat as judges, and dispensed prizes to the conquerors; till what was originally amusement, became at length a matter of such importance, as to interest great cities and entire nations in its practice. Hence arose an eagerness to excel, in hopes of being one day crowned conquerors in the public games, which was the highest honour a mortal could arrive at: nay, they imagined, that even the gods were not insensible of what men were so captivated with; and, in consequence, introduced the greatest part of these exercises into their religious and funeral ceremonies. The gymnastic art, as appears from Homer's Iliad, lib. 23, where he describes the games at the funeral of Patroclus, was known at the time of the Trojan war. From that description, it appears, that they had chariot-races, boxing, wrestling, foot-races, gladiators, throwing the discus, drawing the bow, and hurling the javelin; and that even then the gymnastic art wanted little of perfection. When Galen says there was no gymnastic art in Homer's days, and that it began to appear no earlier than Plato, he is to be understood of medicinal gymnastics only.

GYMNASTICS, MEDICINAL. According to Plato, one Herodicus, a little prior to Hippocrates, was the first who introduced this art into physic; and his successors, convinced of its usefulness improved it. Hippocrates has given instances of it, where he treats of exercise in general, and of the particular effects of walking with regard to health; also of the different sorts of races on foot or horseback; leaping, wrestling, the exercise of the suspended ball, chironomy, unctions, frictions, rolling in the sand, &c. But as physicians did not adopt all the gymnastic exercises in their practice, it came to be divided between them and the masters of martial and athletic exercises, who kept schools, the number of which was greatly increased in Greece. The Romans, adopting the military and athletic exercises of the Greeks, advanced them to the utmost pitch of magnificence. But the declension of the empire involved the arts in its ruin, and, among

others gymnastics and medicine; which last unhappily then relinquished the title it had to the former, and has neglected to resume it ever since.

GYMNOSOPHISTS, [*Γυμνοσophισται*, Greek, i. e. a naked philosopher,] a set of Indian philosophers, famous in antiquity, so called from their going naked. They, however, did not absolutely go naked: but only clothed themselves no farther than modesty required. There were some of these sages in Africa; but the most celebrated of them were in India. In general, the Gymnosophists were wise and learned men; their maxims and discourses, recorded by historians, do not savour of a barbarous education, but are the result of great sense and deep thought. They kept up the dignity of their character to so high a degree, that it was never their custom to wait upon any body, not even upon the princes. They believed the immortality and transmigration of the soul: they placed the chief happiness of man in a contempt of the goods of fortune and the pleasures of sense, and gloried in having given faithful and disinterested counsels to princes and magistrates. Apuleius describes the Gymnosophists thus: "They are all devoted to the study of wisdom, both the elder masters and the younger pupils: and what to me appears the most amiable thing in their character is, that they have an aversion to idleness and indolence: accordingly, as soon as the table is spread, before a bit of victuals be brought, the youths are all called together from their several places and offices, and the masters examine them what good they have done since the sunrise: here one relates something he has discovered by meditation; another has learned something by demonstration; and as for those who have nothing to allege why they should dine, they are turned out to work fasting."

GYMNOSPERMIA, in botany, from *γυμνός*, naked, and *σπέρμα*, seed; the first order in Linnæus's class of didynamia. It comprehends those plants of that class which have naked seeds. The seeds are constantly four in number, except in one genus, viz. phryma, which is monospermous.

GYMNOTHORAX, the *murana*, in natural history, a genus of fishes of the order Apodes. Body eel-shaped, no pectoral fins; spiracle single, on each side of the neck, small oval, and uncovered. There are four species according to Gmelin, but Shaw enumerates eleven. The *G. romana* abounds on the Mediterranean coasts, and attains nearly the size of the common eel.

GYMNOTUS, *gymnote*, a genus of fishes, of the order apodes. The generic character is, head with lateral opercula; tentacula two on the upper lip; eyes covered by the common skin; gill-membrane five-rayed; body compressed, without dorsal fin (in most species), but carinated by a fin beneath. It has nine species.

GYMNOTUS ELECTRICUS, or **ELECTRICAL GYMNOTE**, is a native of the warmer regions of Africa and America, where it inhabits the larger rivers, and is particularly found in those of Surinam. In Africa it is said chiefly to occur in the branches of the river Senegal. It is a fish of a disagreeable appearance; bearing a general resemblance to a larger eel, though somewhat thicker in proportion, and of a much darker colour, being commonly of an uniform blackish-brown. It is usually seen of the length of three or four feet, but is said to arrive at 10 feet in length. It was first made known to the philosophers of Europe about the year 1671, when its wonderful properties were announced to the French Academy by Mons. Richer. This account however seems to have been received with a degree of cautious scepticism by the major part of European naturalists; and it was not till towards the middle of the last century that a full and general conviction appears to have taken place; the observations of Mons. Condamine, Mr. Ingram, Mr. Gravesend, and others, then conspiring to prove that the power of this animal consists in a species of real electricity, being conducted by similar conducting substances, and intercepted by others of an opposite nature. Thus, on touching the fish with the fingers, the same sensation is perceived as on touching a charged phial; being sometimes felt as far as the elbows; and if touched by both hands, an electric shock is conveyed through the breast in the usual manner. Fermin, in particular, who, during his residence in Surinam, had frequent opportunities of examining the animal, demonstrated by experiment that 14 slaves, holding each other by the hands, received the shock at the same instant; the first touching the fish with a stick, and the last dipping his hand into the water in which it was kept. The experiments of Dr. Bancroft

croft were equally satisfactory. It is by this extraordinary faculty that the gymnotus supports its existence: the smaller fishes and other animals which happen to approach, being instantly stupefied, and thus falling an easy prey to the electrical tyrant. So powerful is the shock which this fish in its native waters, is capable of exerting, that it is said to deprive almost entirely of sense and motion those who are exposed to its approach, and is therefore much dreaded by those who bathe in the rivers which it inhabits; yet it is used as an article of food. It has been affirmed that the gymnotus electricus, even for some time after its death, cannot be touched without feeling its electric shock. This is by no means incredible, when we consider the effect of the Galvanic pile, so well known to modern philosophers. See Plate LV.

GYNÆCEUM, in antiquity, the apartment of women, a separate room in the inner part of the house, where they employed themselves in spinning, weaving, and needle-work.

GYNÆOCOCRATUMENI, [from *gynē*, woman, and *κρατος* (AEVOG, vanquished,)] an ancient people of Sarmatia Europæa, inhabiting the E. banks of the Tanais, near its influx into the Palus Mæotis: thus called because they were under the dominion of women.

GYNANDRIA, [from *gynē*, a woman, *andros*, a man,] the 20th class in the sexual system, consisting of plants with hermaphrodite flowers, in which the stamina are placed upon the style, or, a pillar-shaped receptacle, resembling a style, which rises in the middle of the flower, and bears both the stamina and pointal. See BOTANY. The flowers of this class, says Linnæus, have a monstrous appearance, arising from the unusual situation of the parts of fructification.

GYNOPOGON, a genus of the pentandria monogynia class and order. Calyx half five-cleft; corolla five-parted; stigma globular, two-lobed; berry pedicelled, sub-globular; seed cartilaginous. There are three species, herbs of the South Sea islands.

GYPSIES, or **EGYPTIANS**, an outlandish tribe of vagabonds, called Bohemians in France, and Gittanos in Spain; who, disguising themselves in uncouth habits, smearing their faces and bodies, and speaking a canting language, wander up and down, under pretence of telling fortunes, curing diseases, &c. abuse the people, trick them out of their money, and steal all they can come at. They are a strange kind of commonwealth of wandering impostors and jugglers, who made their first appearance in Germany, about the beginning of the 16th century. Munster, who is followed and relied upon by Spelman, fixes the time of their appearance to 1417; but as he owns, that the first whom he ever saw were in 1529, it is probably an error of the press for 1517; especially as, when Sultan Selim conquered Egypt in 1517, several of the natives refused to submit to the Turkish yoke, and revolted under one Zinganeus; whence the Turks called them Zinganees; but being at length surrounded and banished, they agreed to disperse in small parties all over the world, where their supposed skill in the black art gave them an universal reception in that age of superstition and credulity. In a very few years they gained such a number of idle proselytes, (who imitated their language and complexion,) that they became troublesome, and even formidable to most of the states of Europe. Hence they were expelled from France in 1560, and from Spain in 1591. And the government of England took the alarm much earlier. A very circumstantial ac-

count of this singular race of men has been lately given in an Inquiry concerning them, written by H. M. G. Grellman, and translated by Mr. Raper. It is incredible how this swarm of banditti have spread over the earth. They wander about in Asia, and Africa, and most of the European nations. Spain is supposed by Mr. Twiss to contain 40,000, by others 60,000; and by some 120,000. But in Sept. and Oct. 1800, they were almost totally extirpated by the plague. They abound in Italy, and are scattered through France, Germany, Denmark, Sweden, and Russia. Europe contains more than 700,000 of these vagabonds. For near four centuries they have wandered through the world; and in every region, and among every people, whether barbarous or civilized, they have continued unchanged. Their origin has been generally believed to be from Egypt. Thomasius, Salmon, and Sig. Griselin, have endeavoured to prove it. M. Grellman, however, traces it from Hindostan, and the cause of their emigration from the bloody wars of Timur Beg in India, in 1408-9.

GYPSOPHILA, in botany, a genus of the digynia order, and decandria class of plants; natural order, Caryophyllæ. Calyx monophyllous, campanulated, angulated; petals five, ovate, sessile; capsule globose, unilocular. It has twelve species.

GYPSUM, **PLASTER-STONE**: a substance very abundant in nature, and which was well known to the ancients. It is now called the sulphate of lime. It is found in every part of the earth, sometimes composing entire mountains. Sulphate of lime is insipid, white, and soft to the touch. Water will not hold a 500th part of it in solution. Exposed to heat it appears to effervesce, which phenomenon is caused by the expulsion of water. It becomes opaque, and falls into powder. This powder, when its water has been driven off by the application of a red heat, absorbs water rapidly, so that if it be formed into a paste with water, it dries in a few minutes. In this state it is called plaster of Paris, and is employed for forming casts, and for a variety of purposes in the art of statuary.

GYRATION, [*gyro*, Lat.] the turning of any thing about.

GYRINUS, **WATER-FLEA**: in natural history, a genus of insects of the order coleoptera. Antennæ cylindrical; jaws horny, one-toothed, sharp-pointed; eyes four, two above and two beneath; thorax and shells margined, the latter shorter than the body; legs formed for swimming. The insects of this genus are to be found on the surface of waters, on which they run, and describe circles with a great degree of swiftness. There are eleven species. The most remarkable European species is the *gyrinus natator*, a small insect, about a quarter of an inch in length, of an oval shape, with somewhat sharpened extremities, and of a black or grey-black colour, with so lucid a surface as to shine like a piece of looking-glass in the full sunshine. It is an inhabitant of the waters, and is chiefly found in rivulets, being generally seen in great multitudes, and in very brisk motion. It is difficult to catch, diving with astonishing celerity when disturbed; the hinder legs being very broad, finely webbed with minute hairs, and most curiously formed for exercising the office of fins or oars.

GYROMANCY, [from *gyron*, to turn round, and *μαντις*, magic,] a kind of divination performed by walking round in a circle.

GYRON, in heraldry, an ordinary of two straight lines, issuing from divers parts of the escutcheon, and meeting in the Fesse-point.

H.

H is the eighth letter in our alphabet, and the sixth consonant. It has a distinct sound, formed in a particular manner by the organs of speech, which will appear by the words *all* and *hall*, *cat* and *heat*, *arm* and *harm*, *ear* and *hear*, *at* and *hat*, &c. as pronounced with or without the *h*. It is pronounced by a strong expiration of the breath between the lips, closing, as it were, by a gentle motion of the lower jaw to the upper, and the tongue nearly

approaching the palate. It seems to be agreed, that our *H* which is the same with that of the Romans, derived its figure from the Hebrew ה. The Phœnicians, and most ancient Greeks and Romans, used the same figure with our *H*, which in the series of all these alphabets keeps its primitive place, being the eighth letter; though the Θ afterwards occupied its place in the Greek alphabet, and its form was changed to X; while its former figure, *H*,

H, was used for the seventh letter *Eta*, or long *e*. H subjoined to *c*, sometimes gives it the guttural sound, as in *chaos*, sometimes the sound of *sh*, as in *Charlotte*; but more frequently that of *tsh*, as in *charity*, *chit-chat*, *church*, &c. and not seldom that of *k*, as in *character*, *Achilles*, &c. though the latter and all other Greek proper names ought rather to have the guttural sound, agreeably to their original pronunciation. H, subjoined to *p* and *t*, also alters the sound of these letters; giving the former the sound of *f*, as in *philosophy*, &c. and the latter that of the Greek θ , as in *theology*, *truth*, &c. and in some English words, as *the*, *that*, *these*, &c. a still harder sound. As an abbreviation, H was used by the ancients to denote *homo*, *hæres*, *hora*, &c. Thus H. B. stood for *hæres bonorum*; and H. S. corruptly for L. S. sesterce; and H. A. for Hadrianus. As a numeral, H denotes 200; and with a dash over it, 200,000.

HAAG, or HAG, a town in Bavaria. Lon. 12. 23. E. Lat. 48. 16. N.

HAANO, one of the Hapæe islands discovered by Captain Cook, in 1777, in the S. Pacific Ocean. Lon. 185. 43. E. Lat. 19. 41. S.

HAARBURG, a town and fort of Lunenburg Zell, seated on the Seeve, seven miles S. of Hamburg.

HABAKKUK. [הבקק, Heb. *i. e.* a wrestler,] one of the twelve lesser prophets, whose prophecies are taken into the canon of the Old Testament. There is no precise time mentioned in Scripture when he lived; but from his predicting the destruction of Jerusalem by the Chaldeans, it is evident that he prophesied before Zedekiah, probably about the time of Manasseh. He is reported to have been the author of several prophecies which are not extant; but all that are indisputably his are contained in three chapters. In these he complains pathetically of the vices of the Jews; foretells their punishment by the Chaldeans; the defeat of the vast designs of Jehoiakim; with the conquests of Nebuchadnezzar, his metamorphosis, and death. The third chapter is a prayer to God, whose majesty he describes with the utmost grandeur and sublimity of expression.

HABDALA, [Heb. *i. e.* distinction, from *בדל*, to separate,] a ceremony of the Jews observed on the sabbath evening. When all the family is come home, they light a taper or lamp, with two wicks at least. The master of the family then takes a cup, with some wine, mixed with fragrant spices, and having repeated a passage of scripture, (*e. g.* Psal. cxvi. 13. or Esth. viii. 16,) he blesses the wine and spices. Afterwards he blesses the light of the fire; and then casts his eyes on his hands and nails, as remembering that he is going to work; to signify, that the sabbath is over, and separated from the day of labour which follows. After the ceremony is over, and the company breaks up, they wish one another, not a good night, but a good week.

HABEAS CORPUS, [Lat. *i. e.* a writ, the which, a man indicted of some trespass, being laid in prison for the same, may have out of the king's-bench, thereby to remove himself thither at his own costs, and to answer the cause there. Habeas Corpus is the great remedy in cases of false imprisonment. A general recourse is had, in behalf of persons aggrieved by illegal imprisonment, to this writ, the most celebrated in the English law. Of this there are various kinds made use of by the courts at Westminster, for removing prisoners from one court into another for the more easy administration of justice. Such is the habeas corpus ad respondendum, when a man hath a cause of action against one who is confined by the process of some inferior court; in order to remove the prisoner, and charge him with this new action in the court above. Such is that ad satisfaciendum, when a prisoner hath had judgement against him in an action, and the plaintiff is desirous to bring him up to some superior court to charge him with process of execution. Such are also those ad prosequendum, testificandum, deliberandum, &c.; which issue when it is necessary to remove a prisoner, in order to prosecute or bear testimony in any court, or to be tried in the proper jurisdiction wherein the fact was committed. Such is, lastly, the common writ ad faciendum et recipiendum, which issues out of any of the courts of Westminster-hall, when a person is sued in some inferior jurisdiction, and is desirous to remove the action into the superior court; commanding the inferior judges to produce the body of the defendant, together with the day and cause of his caption and detainer (whence the writ is frequently denominated an habeas corpus cum causa,) to do and

receive whatsoever the king's court shall consider in that behalf. This is a writ grantable of common right, without any motion in court; and it instantly supersedes all proceedings in the court below. But, to prevent the surreptitious discharge of prisoners, it is ordered by stat. 1 & 2 P. & M. c. 13, that no habeas corpus shall issue to remove any prisoner out of any gaol, unless signed by some judge of the court out of which it is awarded. And, to avoid vexatious delays by removal of frivolous causes, it is enacted by stat. 21 Jac. I. c. 23, that, where the judge of an inferior court of record is a barrister of three years standing, no cause shall be removed from thence by habeas corpus or other writ, after issue or demurrer deliberately joined: that no cause, if once remanded to the inferior court by writ of procedendo or otherwise, shall ever afterwards be again removed: and that no cause shall be removed at all, if the debt or damages laid in the declaration do not amount to the sum of five pounds. But an expedient having been found out to elude the latter branch of the statute, by procuring a nominal plaintiff to bring another action for 5*l.* or upwards (and then by the course of the court, the habeas corpus removed both actions together,) it is therefore enacted by stat. 12 Geo. I. c. 29, that the inferior court may proceed in such actions as are under the value of 5*l.* notwithstanding other actions may be brought against the same defender to a greater amount. But the great and efficacious writ, in all manner of illegal confinement, is that of habeas corpus ad subjiciendum; directed to the person detaining another, and commanding him to produce the body of the prisoner, with the day and cause of his caption and detention, ad faciendum, subjiciendum, et recipiendum, to do, submit to, and receive, whatsoever the judge or court awarding such writ shall consider in that behalf. This is a high prerogative writ, and therefore by the common law issuing out of the court of king's-bench, not only in term-time, but also during the vacation, by a fiat from the chief justice, or any other judge, and running into all parts of the king's dominions: for the king is at all times intitled to have an account why the liberty of any of his subjects is restrained, wherever that restraint may be inflicted. If it issues in vacation, it is usually returnable before the judge himself who awarded it, and he proceeds by himself thereon; unless the term should intervene, and then it may be returned in court. The oppression of an obscure individual gave birth to the famous habeas corpus act, 31 Car. II. c. 2, which is frequently considered as another magna charta of the kingdom; and by consequence has also in subsequent times reduced the method of proceeding on these writs (though not within the reach of that statute, but issuing merely at the common law) to the true standard of law and liberty. The statute itself enacts, 1. That the writ shall be returned and the prisoner brought up, within a limited time according to the distance, not exceeding in any case twenty days. 2. That such writs shall be endorsed, as granted in pursuance of this act, and signed by the person awarding them. 3. That on a complaint and request in writing, by or on behalf of any person committed and charged with any crime, (unless committed for treason or felony expressed in the warrant, or for suspicion of the same, or as accessory thereto before the fact, or convicted or charged in execution by legal process,) the lord chancellor, or any of the twelve judges in vacation, upon viewing a copy of the warrant, or affidavit that a copy is denied, shall (unless the party has neglected for two terms to apply to any court for his enlargement) award a habeas corpus for such prisoner, returnable immediately before himself or any other of the judges; and upon the return made shall discharge the party, if bailable, upon giving security to appear and answer to the accusation in the proper court of judicature. 4. That officers and keepers, neglecting to make due returns, or not delivering to the prisoner or his agent within six hours after demand, a copy of the warrant of commitment, or shifting the custody of a prisoner from one to another without sufficient reason or authority, (specified in the act,) shall for the first offence forfeit 100*l.* and for the second 200*l.* to the party grieved, and be disabled to hold his office. 5. That no person, once delivered by habeas corpus, shall be re-committed for the same offence, on penalty of 500*l.* 6. That every person committed for treason or felony shall, if he require it the first week of the next term, or the first day of the next session of oyer and terminer, be indicted in that term or session, or else admitted to bail; unless the king's witnesses cannot be produced at that time: and if acquitted, or if not indicted and tried

in the second term or session, he shall be discharged from his imprisonment for such imputed offence: but that no person, after the assizes shall be opened for the county in which he is detained, shall be removed by habeas corpus, till after the assizes are ended; but shall be left to the justice of the judges of assize. 7. That any such prisoner may move for and obtain his habeas corpus, as well out of the chancery or exchequer, as out of the king's-bench or common-pleas; and the lord-chancellor or judges denying the same, on sight of the warrant, or oath, that the same is refused, forfeit severally to the party grieved the sum of 500*l*. 8. That the writ of habeas corpus shall run into the counties-palatine, cinque-ports, and other privileged places, and the islands of Jersey and Guernsey. 9. That no inhabitant of England (except persons contracting, or convicts praying to be transported; or having committed some capital offence in the place to which they are sent) shall be sent prisoner to Scotland, Ireland, Jersey, Guernsey, or any places beyond the seas, within or without the king's dominions: on pain that the party committing, his advisers, aiders, and assistants, shall forfeit to the party grieved a sum not less than 500*l*. to be recovered with treble costs; shall be disabled to bear any office of trust or profit; shall incur the penalties of *præmunire*; and shall be incapable of the king's pardon. This is the substance of that great and important statute: which extends only to the case of commitments for such criminal charge, as can produce no inconvenience to public justice by a temporary enlargement of the prisoner; all other cases of unjust imprisonment being left to the habeas corpus at common law. But even upon writs at the common law, it is now expected by the court, agreeably to ancient precedents and the spirit of the act of parliament, that the writ should be immediately obeyed, without waiting for any alias or pluries; otherwise an attachment will issue. By which admirable regulations, judicial as well as parliamentary, the remedy is now complete for removing the injury of unjust and illegal confinement. A remedy the more necessary, because the oppression does not always arise from the ill nature, but sometimes from the mere inattention, of government. For it frequently happens in foreign countries (and has happened in England during the temporary suspensions of the statute,) that persons apprehended upon suspicion have suffered a long imprisonment, merely because they were forgotten.

HABERDASHER, in commerce, a seller of hats, or of small wares. The master and wardens of the company of haberdashers in London, calling to their assistance one of the company of cap-pers, and another of the hat-makers, and mayors, &c. of towns, may search the wares of all hatters that work hats with foreign wool, and have not been apprentices to the trade, or who dye them with any thing but copperas and galls, or woad and madder; in which case they are liable to penalties, by stat. 8 Eliz. c. 7, and 3 Geo. II. c. 22.

HABERE FACIAS SASINAM, a writ judicial, which lies where a man has recovered lands, commanding the sheriff to give possession of them.

HABERGEON, or **HABERGETUM**, [from *haut*, Fr. high, and *berg*, armour,] was a coat of mail; an ancient piece of defensive armour, in form of a coat, descending from the neck to the middle, and formed of little iron rings or meshes, linked into each other.

HABILIMENTS OF WAR, in our ancient statutes, signify armour, harness, utensils, or other provisions, for war, without which there is supposed no ability to maintain war.

HABINGTON, WILLIAM, an English poet and historian, was the son of Thomas Habington, Esq. He was born in 1605, at Hendlip in Worcestershire; and educated at St. Omers and Paris. He died in 1654, and left several MSS. in the hands of his son. His printed works are, 1. Poems under the title of *Castura*. 2. The Queen of Arragon, a Tragi-comedy. 3. Observations upon History. 4. The History of Edward IV. King of England, written in a very florid style, and published at the desire of Charles I.

HABIT, [*habitus*, Lat.] in philosophy, an aptitude or disposition either of mind or body, acquired by a frequent repetition of the same act. Custom and habit have such influence upon many of our feelings, by warping and varying them, that their operations demand the attention of all who would be acquainted with human nature. The subject, however, is intricate. Some pleasures are fortified by custom: and yet custom begets familiarity, and conse-

quently indifference. In many instances, satiety and disgust are the consequences of reiteration: again, though custom blunts the edge of distress and of pain, yet the want of any thing to which we have been long accustomed is a sort of torture. Whatever be the cause, it is certain we are much influenced by custom: it has an effect upon our pleasures, upon our actions, and even upon our thoughts and sentiments. Habit makes no figure during the vivacity of youth: in middle age it gains ground; and in old age governs without control. In that period of life, generally speaking, we eat at a certain hour, take exercise at a certain hour, go to rest at a certain hour, all by the direction of habit: nay, a particular seat, table, bed, comes to be essential; and a habit in any of these cannot be controlled without uneasiness. Any slight or moderate pleasure, frequently reiterated for a long time, forms a peculiar connection between us and the thing that causes the pleasure. This connection termed habit, has the effect to awaken our desire for that thing when it does not return as usual. During the course of enjoyment, the pleasure rises insensibly higher and higher till a habit be established; at which time the pleasure is at its height. It continues not, however, stationary; the same customary reiteration which carried it to its height, brings it down again by insensible degrees. Those things which at first are but moderately agreeable, are the aptest to become habitual. Spirituous liquors, at first scarce agreeable, readily produce an habitual appetite: and custom prevails so far, as even to make us fond of things originally disagreeable, such as coffee, assafoetida, tobacco, opium, &c. A walk upon the quarter-deck, though intolerably confined, becomes, however, so agreeable by custom, that a sailor in his walk on shore confines himself commonly within the same bounds. Improper habits are easily acquired, but are not easily given up; hence it is necessary for a man who would conduct himself with propriety, to guard against the appearances of wrong habits; and if they have already taken place, to exert all his powers in order to eradicate them. Lord Kaimes in his *Elements of Criticism* has treated this subject at considerable length. And Dr. Cullen in his *Lectures on the Materia Medica*, (first edition) shews the effects of custom and habit on the animal œconomy.

HABIT, in medicine, denotes the settled constitution of the body, or the habitude of any thing else, as the structure or composition of a body, or the parts thereof.

HABIT is also used for a dress or garb, or the composition of garments, wherewith a person is covered; in which sense we say, the habit of an ecclesiastic, of a religious, &c. a military habit, &c. The principal part of the dress worn by the Jews and Greeks was by the *ἵματιον* and the *χιτών*. The *ἵματιον* was an upper garment, consisting of a loose square piece of cloth wrapped round the body; the *χιτών* was an under-garment or tunic, which was fastened round the body and embraced it closely, falling down to the middle of the thigh. A person divested of the upper garment, in the eastern language, was styled naked, and in this sense David danced naked before the ark. The several sorts of garments in use with both sexes, amongst the Romans, were the toga, tunica, peluna, lacerna, chlamys, paludamentum, lana, stola, pallium, or palla. See **TOGA**, &c. See also **PRIESTS**.

HABITE AND REPUTE, in Scots law, the common opinion of the people, among whom a person lives, with respect to any circumstance relating to him.

HABITUDE, among schoolmen, the respect or relation one thing bears to another. Some consider habitude as a genus, and subdivide it into two species; where it is considered as quiescent, they call it respect; where as moved, relation: to which some add a third species, considered in respect of figure, which they call mode. See **RELATION**, &c.

HABITUDE is also used by philosophers for what we commonly call habit, or a certain disposition or habitude for the performing or suffering of certain things, acquired by repeated acts of the same kind.

HACHA, a sea-port town of Terra Firma, seated at the mouth of the Hacha. Here the Spanish galleons touch at their arrival in S. America, and send expresses to all the settlements to give them notice. Lon. 72 8. W. Lat. 11. 28. N.

HACKNEY-COACHES, coaches exposed to hire in the streets of London, and other great cities, at rates fixed by authority. These first began to ply in London, in 1625, when they were only twenty in number; but in 1635 they were so much increased

creased, that king Charles I. issued out an order of council to restrain them. In 1637, he allowed fifty hackney-coachmen, each of whom might keep twelve horses. In 1652, their number was limited to 200; and in 1654, it was extended to 300. In 1661, 400 were licensed, at 5*l.* each annually. In 1694, 700 were allowed, and taxed by the 5 and 6 of W. and M. at 4*l.* a year each. By 9 Anne c. 23, 800 coaches were allowed in London and Westminster; but by 8 Geo. III. cap. 24, the number is increased to 1000, which are licensed by commissioners, and pay a duty of 5*s.* per week. The fare of hackney-coachmen in London, or within ten miles of it, is, 12*s.* 6*d.* per day. By the hour it is 1*s.* 6*d.* for the first, and 1*s.* for every hour after; and 1*s.* for any distance not exceeding a mile and a half; or 1*s.* 6*d.* two miles. Hackney-coachmen refusing to go at, or exacting more than, their limited hire, are subject to a forfeit of from 10*s.* to 3*l.* which the commissioners have power to determine. Every hackney-coach must have check-strings, and every coachman plying without them incurs a penalty of 5*s.* The drivers must give way to persons of quality and gentlemen's coaches, under the penalty of 5*l.* The duty arising from licences to hackney-coaches and chairs in London, forms a branch of the king's extraordinary and perpetual revenue, governed by commissioners, and is a public benefit; as the expence of it is not felt, and its regulations have established a competent jurisdiction, whereby a very refractory race of men are kept in order. For further information upon this subject, see COACH, HACKNEY.

HADDINGTON, an ancient borough of Scotland in East Lothian, which joins with Juddburgh, Dunbar, Lauder, and North Berwick, in sending a member to Parliament. It lies 17 miles E. of Edinburgh.

HADDINGTON, or **HADDINGTON-SHIRE**. See **LOTHIAN**, EAST.

HADDOCK. See **GADUS**.

HADDON, Dr. **WALTER**, a great restorer of the learned languages in England, was born in 1516. He distinguished himself by writing Latin in a fine style, which he acquired by a constant study of Cicero. He was a strenuous promoter of the reformation under Edward VI. and succeeded bishop Gardiner in the mastership of Trinity-hall, Cambridge. He concealed himself in Mary's reign; but acquired the favour of Queen Elizabeth, who sent him one of the three agents to Bruges in 1566, to restore commerce between England and the Netherlands. He was also engaged with Sir John Cheke in drawing up in Latin that useful code of ecclesiastical law, published in 1571 by the learned John Fox, under the title of "Reformatio Legum Ecclesiasticarum;" his other works are published under the title of "Lucubrations." He died in 1572.

HADERSLEBEN, a sea-port town of Denmark, in Sleswick. Lon. 9. 35. E. Lat. 55. 24. N.

HADES, in Scripture, sometimes signifies the invisible regions of the dead, sometimes the place of the damned, and sometimes the grave. In Greek authors it signifies the regions of the dead. See **HELL**.

HADLEY, a town of Suffolk, seated on the Preston. Lon. 1. 6. E. Lat. 52. 7. N.

HADLEY'S QUADRANT. See **NAVIGATION**.

HADRAMAUT, a fertile province of Arabia Felix, bounded on the W. by Yemen, N. by the Desert, N. E. by Oman, and S. E. by the Sea; containing several large towns and sea-ports.

HADRAMAUT, the capital of the above province, 150 miles W. of Carissen. Lon. 45. 30. E. Lat. 15. 0. N.

HÆMAGOGOS, among physicians, a compound medicine, consisting of fetid and aromatic simples, mixed with black hellebore, and prescribed in order to promote the menstrua and hamorrhoidal fluxes; as also to bring away the lochia.

HÆMANTHUS, the **BLOOD-FLOWER**: a genus of the monogynia order, and hexandria class of plants; natural order, Spatheaceæ. Involute six-leaved, many-flowered; corolla six-parted, superior; berry three-celled. There are eight species.

HÆMATITES, the **BLOOD-STONE**, a hard mineral substance, red, black, or purple, but the powder of which is always red. It is found in masses, spherical, semi-spherical, pyramidal, or cellular, *i. e.* like a honeycomb. It contains a large quantity of iron. The great hardness of hæmatites renders it fit for burnishing metals. See Plate LXVII.

HÆMATOPUS, the **SEA-PYE**, in ornithology, a genus belonging to the order grallæ. Beak compressed, with an equal wedge-shaped point; nostrils linear; toes three, without nails. The only species is the

H. OSTRALÉGUS, or **OYSTER-CATCHER**, a native of Europe and America. It feeds upon shell-fish near the sea-shore, particularly oysters, and limpets. On observing an oyster which gapes wide enough for the insertion of its bill, it thrusts it in, and takes out the inhabitant. The young are said to be hatched in about three weeks. These birds are wild when in flocks; yet are easily tamed, if taken young.

HÆMATOXYLON, or **HÆMATOXYLUM**, **Logwood**, or **CAMPEACHY-WOOD**; a genus of the monogynia order, and decandria class of plants; natural order, Lomentaceæ. Calyx quinquepartite; petals five; capsule lanceolated, unilocular, and bivalved; valves navicular or keeled like a boat. Of this genus there is only one species, which grows naturally in the bay of Campeachy at Honduras, and other parts of the Spanish West Indies, where it rises from 16 to 24 feet high. The trees are cut up into billets or junks, the bark and white sap of which are chipped off, and the red part, or heart, is sent to England for sale. See **Logwood**.

HÆMORRHAGIA, or **HÆMORRHAGY**, [from *αιμα*, blood, and *εσσυει*, to burst forth,] in medicine, a flux of blood at any part of the body; arising either from a rupture of the vessels, when too full or too much pressed; or from an erosion of them, when the blood is too sharp and corrosive. See **MEDICINE** and **SURGERY**.

HÆMORRHOIDAL, an appellation given by anatomists to the arteries and veins going to the intestinum rectum.

HÆMORRHOIDS, or **PILES**, an issue of blood from the hamorrhoidal vessels. See **MEDICINE**.

HÆMUS, in ancient geography, a ridge of mountains running from Illyricum towards the Euxine.

HÆRETICO COMBURENDO, a writ which anciently lay against an heretic, who, having once been convicted of heresy by his bishop, and having abjured it, afterwards falling into it again, or into some other, was thereupon committed to the secular power.

HAERLEM. See **HARLEM**.

HAG, in zoology. See **MYXINE**.

HAGAR, [הָגָר, *i. e.* a stranger,] a native of Egypt, the servant of Sarah, concubine of Abraham, mother of Ishmael, and ancestor of the Arabians. Her history, and the repeated divine interpositions for the preservation of her and her son, are recorded in Gen. xvi. and xxi.

HAGARENES, or **HAGARITES**, a branch or tribe of the descendants of Ishmael, so named from his mother. Some make the name synonymous with Ishmaelites, Arabians, and Saracens; but Asaph, in Psalm lxxxiii. ver. 6, mentions them as distinct from the other Ishmaelites. They dwelt in Arabia Felix, according to Pliny. Strabo joins them with the Nabathæans and Chavlotæans, whose habitation was rather in Arabia Deserta. Others think their capital was Petra, or Agra, and if so, they dwelt in Arabia Petræa. The Reubenites, in the days of Saul, made war with the Hagarites, and became masters of their country E. of Gilead. This therefore was the true country of the Hagarenes.

HAGIAZ, a town of Arabia, in Hedsjas.

HAGIOGRAPHIA, [from *ἅγιος*, holy, and *γραφω*, to write,] those books of Scripture, called by the Jews *Cetuvim*. The name is very ancient. St. Jerom makes mention of it. The Jews divide the sacred writings into three classes: 1. The law, or the five books of Moses: 2. The Prophets, which they call *Neviim*: and the *Cetuvim* כְּתוּבִים, called by the Greeks, &c. *Hagiographa*; comprehending the book of Psalms, Proverbs, Job, Daniel, Ezra, Nehemiah, Chronicles, Canticles, Ruth, Lamentations, Ecclesiastes, and Esther. Kimchi, Maimonides, and Elias Kevita, call these books the Writings, by way of eminence, as being written by immediate inspiration of the Holy Spirit.

HAGUE, a town of Batavia, in the department of Delft; and late province of South Holland. In Latin it is called *Haga Comititis*; in French, *La Haye*; in Dutch, *der Haag*, or *'s Graavenhage*; *i. e.* the Earl's Grove, from the wood near which it is built, and in which the earls of Holland had a country-house. It is one of the most considerable towns in the republic, pleasantly situated,

situated, and exceeding beautiful. It is 12 miles N. W. of Rotterdam, and 32 S. W. of Amsterdam.

HAGUENAU, a town of France, in the department of the Lower Rhine, anciently an imperial town.

HAIL, in natural history, a meteor generally defined frozen rain, but differing from it in that the hailstones are not formed of single pieces of ice, but of many little spherules agglutinated together. Neither are these spherules all of the same consistence; some being hard and solid like perfect ice; others soft, and mostly like snow hardened by a severe frost. Sometimes the hailstone has a kind of core of this soft matter; but more frequently the core is solid and hard, while the outside is formed of a softer matter. Hailstones are of various figures; some round, others pyramidal, crenated, angular, thin, and flat, and some stellated, with six radii like the small crystals of snow. Natural historians record various instances of surprising showers of hail, in which the hailstones were of extraordinary magnitude. Mezeray, speaking of the war of Lewis XII. in Italy, in 1510, relates, that there was for some time a horrible darkness, thicker than that of night; after which the clouds broke into thunder and lightning, and there fell a shower of hailstones, or rather (as he calls them) pebble-stones, which destroyed all the fish, birds, and beasts, of the country. It was attended with a strong smell of sulphur; and the stones were of a blueish colour, some of them weighing 100 lb. *Hist. de France*, Tom. II. p. 339. At Lisle in Flanders, in 1686, hailstones fell of a very large size; some of which contained in the middle a dark brown matter, which, thrown on the fire, gave a very great report. *Philos. Trans.* No. 203. Dr. Halley and others relate, that in Cheshire, Lancashire, &c. April 29, 1697, a thick black cloud, coming from Caernarvonshire, disposed the vapours to congeal in such a manner, that for about the breadth of two miles, which was the limit of the cloud, in its progress for 60 miles, it did inconceivable damage; not only killing all sorts of fowls and other small animals, but splitting trees, knocking down horses and men, and even ploughing up the earth; so that the hailstones buried themselves under ground an inch or an inch and half deep. The hailstones, many of which weighed five ounces and some half a pound, being five or six inches about, were of various figures: some round, others half round; some smooth, others embossed and crenated: the icy substance of them was very transparent and hard, but there was a snowy kernel in the middle of them. In Hertfordshire, May 4, 1697, after a severe storm of thunder and lightning, a shower of hail succeeded, which far exceeded the former: some persons were killed by it, their bodies beat all black and blue; vast oaks were split, and fields of rye cut down as with a scythe. The stones measured from ten to thirteen or fourteen inches about. Their figures were various, some oval, others picked, some flat. *Philos. Trans.* No. 229. On the tops of mountains hailstones, as well as drops of rain, are very small, and continually increase in bulk till they reach the lower grounds. It would seem, therefore, that during their passage through the air, they attract the congealed vapour which increases them in size; or that the vapour they meet with is congealed on them as they fall. Some modern philosophers ascribe the formation of hail to electricity. See **METEOROLOGY**.

HAILBRON, a strong town in Wirtemberg, 5 miles N. E. of Stutgard.

HAINAN, one of the most considerable islands of Asia, subject to China, and belonging to the province of Quang-ton. It has on the N. the province of Quang-si; on the S. the channel between the bank Paracel and the E. coast of Cochinchina; on the W. the same kingdom and part of Tong-king; and on the E. the Chinese sea. Its extent from E. to W. is between 60 and 70 leagues, and from N. to S. 45; and about 480 miles in circumference. Kiun-tcheou-fou is the capital. Hainan lies near San-cian, between 18° and 20° Lat. N.

HAINAULT, a province of the Netherlands, formerly divided between France and Austria, but now wholly belonging to France. It was bounded on the S. by Champagne and Picardy; and extended from N. to S. about 45 miles, and about 48 from E. to W.

HAINBURG, or **HAIMBURG**, a town of Austria, on the Danube, 8 miles W. of Presburgh, and 20 S. S. E. of Vienna.

HAIR, [*har*, Saxon,] 1. One of the common teguments of the body. It is to be found upon all the parts of the body, except

the soles of the feet and palms of the hands. When we examine the hairs with a microscope, we find that they have each a round bulbous root, which lies pretty deep in the skin, and which draws their nourishment from the surrounding humours: that each hair consists of five or six others, wrapt up in a common tegument or tube. Hairs ordinarily appear round or cylindrical; but the microscope also discovers triangular and square ones; which diversity of figure arises from that of the pores, to which the hairs always accommodate their form. Their length depends on the quantity of the proper humour to feed them, and their colour on the quality of that humour: whence, at different stages of life, the colour usually differs. Their extremities split into two or three branches, especially when kept dry, or suffered to grow too long; so that what appears only a single hair to the naked eye, seems a brush to the microscope. The hair of a mouse, viewed by Mr. Derham with a microscope, seemed to be one single transparent tube, with a pith made up of fibrous substances, running in dark lines, in some hairs transversely, in others spirally. The darker medullary lines, he observes, were small fibres convolved, and lying closer together than in the other parts of the hair. They run from the bottom to the top of the hair; and he imagines, may serve to make a gentle evacuation of some humour out of the body. Hence the hair of hairy animals, may not only serve as a fence against cold, &c. but as an organ of insensible perspiration. When a hair is drawn between the fingers from the root towards the point, scarce any friction or resistance is perceived, and no noise is heard; but if it be passed in the same manner between the fingers from the point towards the root, a resistance is felt, a tremulous motion is evident to the touch, and a noise may be distinctly heard. It is obvious therefore, that the texture of the surface of hair is not the same from the root towards the point, as it is from the point towards the root. These observations are equally applicable to the filaments of wool. The ancients held the hair a sort of excrement, fed only with excrementitious matters, and no proper part of a living body. They supposed it generated of the fuliginous parts of the blood, exhaled by the heat of the body to the surface, and there condensed in passing through the pores; and that hair does not feed and grow like the other parts, by a juice circulating within it; but, like the nails, by juxtaposition. But the moderns are agreed, that every hair properly and truly lives, and receives nutriment to fill it like the other parts; which they prove hence, that the roots do not turn grey in aged persons sooner than the extremities, but the whole changes colour at once; which shews that there is a direct communication, and that all the parts are affected alike. In strict propriety, however, it must be allowed, that the life and growth of hairs is of a different kind from that of the rest of the body; and is not immediately derived therefrom, or reciprocated therewith. It is rather of the nature of vegetation. They grow as plants do, or as some plants shoot from the parts of others; from which though they draw their nourishment, yet each has, as it were, its distinct life and economy. They derive their food from some juices in the body, but not from the nutritious juices of the body; whence they may live though the body be starved. Almost the only disease of the hair, besides the remarkable one called *Plica Polonica*, is baldness, or its falling off. For this many remedies have been recommended, but scarce any of them can be depended upon. The juice of burdock, and the lixivial salts of vine-ashes, are said to be efficacious; also the powder of hermodactyls, and the decoction of boxwood. Some authors have given instances of the hair changing, in a short time, its colour, through grief, a fright, &c. &c. Frequent cutting the hair is very beneficial to the ears, eyes, nay, to the whole body; and, if the head be washed or immersed daily in cold water, it will be found an excellent preventive of periodical head-achs. Persons subject to defluxions of humours from the head, to weak eyes and similar complaints, will derive great benefit from shaving the head at certain intervals; as this is the most effectual mode of opening the pores and promoting perspiration. There is no danger of contracting cold from washing or exposing the head, after being rubbed dry, to the open air: and this futile objection should influence only the conduct of those who, from ignorance or prejudice, carry all their exhaled impurities on the surface of the skin, and especially on the head, for a succession of years. Thus, perhaps, arise many states of intellectual derangement, the source of which is seldom suspected. Besides, cleansing

ing the head affords comfortable and pleasing sensations; and the more frequently the hair be cut, it will grow the more speedily; so that this simple expedient may, in some measure, serve as a substitute for a constant blister, or artificial issue. The hair is, by all nations, considered as an ornament to the person, more than as a covering for the head, provided by the beneficent hand of nature. Hence various pomatums, and other secret preparations, have been imposed upon the public, for the purpose of "making the hair grow long and thick." We are no advocates for contrivances, which to our certain knowledge are generally composed of noxious ingredients, such as the calces of lead and mercury. Those persons who cannot be dissuaded from the use of artificial means, may with safety employ a mixture consisting of equal parts of olive oil and spirits of rosemary, to which may be added a few drops of oil of nutmeg. If the hair be rubbed every night with a little of this liniment, and the proportion be very gradually increased, it will answer every purpose to be attained by those boasted preparations which are sold by empirics. Another source of fraud is that of changing the colour of the hair to a darker shade: with this intention various liquid remedies are vended by perfumers, under different alluring appellations. These, however, being likewise prepared from lead, antimony, and other metallic solutions, no prudent person will be induced to purchase them. The only method that can be pursued with impunity, is to cut the hair close to the head, and to pass a leaden comb through it every morning and evening, by which simple practice the hair will assume a darker colour; the perspiration of the head will not be impeded, and, consequently, the health of the individual rather promoted than injured. Hair constitutes a very considerable article of commerce, especially since the fashion of wearing wigs has prevailed among all ranks, and has lately been extended to both sexes. The hair of this, and other northern countries, is preferred to that of the southern climates of Italy, France, &c. The chief quality of hair consists in its being well fed, as it is termed by hair-dressers, so that it be neither too coarse nor too slender. Hence thick hair is less susceptible of the artificial curl, and is disposed to frizzle; but, if it be too delicate, it will retain the curl only for a short time. The length of good hair is usually estimated at 25 inches; and in proportion as it is shorter, it becomes less valuable. There appears to be no stated price for this article; as according to its quality, it is sold at from 5s. to 5l. per ounce: it pays, when imported, a duty of 2s. 4½d. per lb. With respect to the various operations which hair undergoes previously to being manufactured into wigs, we trust the reader will excuse our silence. The hair of beavers, hares, and other animals, is used in various manufactures, especially that of hats, of which they constitute the principal material. If the refuse of the short hair of hides be scattered on arable land, and left there to putrefy, it proves one of the most fertilizing and durable manures. Berthollet found by analysis, that hair yielded from 1152 parts,

Carbonate of ammonia.....	90
Water	179
Oil.....	288
Gases.....	271
Coal.....	324

1152

Sulphuric acid, assisted by heat, dissolves hair. It forms, with the alkalis, an animal soap.

HAIR, in farriery, is commonly called the coat; and, with respect to horses, merits particular consideration. The hair growing on the fetlock, serves as a defence to the prominent part of it, when the animal is travelling on rough, stony roads, or in frosty weather. If the hair on the neck and more exposed parts be close and smooth, it may be concluded that the horse is in health.

HAIR, HORSE, likewise forms a considerable article of trade; it pays on importation a duty of about 11d. per lb. and is partly employed for weaving the covers of the seats of chairs, sofas, &c. but principally for the stuffing of bolsters and mattresses. For the last mentioned purposes, the hair is previously baked, and, in that state, forms one of the most elastic couches, which is incomparably superior to the softer, but enervating, feather-beds.

HAIR OF PLANTS, or DOWN, a general term expressive of all

the hairy and glandular appearances on the surface of plants, to which they are supposed to serve the double purpose of defensive weapons and vessels of secretion. These hairs are minute threads of greater or less length and solidity; some of them visible to the naked eye; whilst others are rendered visible only by the help of glasses. Examined by a microscope, almost all the parts of plants, particularly the young stalks or stems, appear covered with hairs. These appear under various forms; in the leguminous plants, they are generally cylindric; in the mallow-tribe, terminated in a point; in agrimony, shaped like a fish-hook; in nettle, awl-shaped and jointed; and in some compound flowers with hollow or funnel-shaped florets, they are terminated in two crooked points. Probable as some experiments have rendered it, that the hairs on the surface of plants contribute to some original secretion, their principal use seems to be, to preserve the parts in which they are lodged from the bad effects of violent frictions, from winds, from extremes of heat and cold, and such like external injuries.

HAIR-CLOTHS, in military affairs, are large pieces of cloth made with half hair: used for covering the powder in waggons, and upon batteries; also charged bombs, hand-grenades, &c. in magazines.

HAI-TANG, a beautiful Chinese shrub, originally brought from the bottom of the rocks which border the sea-coast. The smell of its leaves has an affinity both to that of the rose and the violet; but it is weaker; and never extends to any great distance.

HAKE, the English name of a fish common in the British sea. See GADUS.

HALBERDS, or HALBERTS, [from *barde*, an axe, and *halle*, a court,] a kind of spears, carried by the sergeants of foot and dragoons. The shaft is about five feet long, and made of ash or other wood. The head is armed with a steel-point, not unlike the point of a two-edged sword. Besides this sharp point which is in a line with the shaft, there is a cross-piece of steel, flat and pointed at both ends; but generally with a cutting edge at one extremity, and a bent sharp point at the other; so that the halbert serves equally to cut down or to push withal. It is also useful in determining the ground between the ranks, and adjusting the files of a battalion. It was anciently a common weapon in the army; where there were companies of halberdiers. It is said to have been used by the Amazons, and afterwards by the Rhätians and Vindélicians about A. D. 570. It was called the Danish axe, because the Danes bore an halbert on the left shoulder. From the Danes it came to the Scots, from the Scots to the English Saxons, and from them to the French.

HALBERSTADT, a late principality of Germany, in the circle of Lower Saxony, bounded on the N.E. by the duchy of Magdeburgh. It was near 40 miles long and 30 broad. The soil is fertile in corn and flax; and there are some woods, though fuel is scarce. The chief towns are Halberstadt, Groningen, Oschersleben, and Osterwick.

HALBERSTADT, the capital of the above late principality, 34 miles S. S. E. of Brunswick.

HALBERT, or HALBARD. See HALBERD.

HALCYON. See ALCEO.

HALCYON DAYS, in antiquity, a name given to seven days before and as many after the winter-solstice; when the halcyon, invited by the calmness of the weather, laid her eggs in nests built in the rocks, close by the brink of the sea. Hence the phrase became proverbial.

HALDE, JOHN BAPTIST DU, a learned French Jesuit, born at Paris in 1674. He was well versed in Asiatic geography, and compiled a work entitled "Grande description de la Chine & de la Tartarie," from original memoirs of the Jesuitical missionaries, in 4 vols. folio. He was also concerned in a collection of letters begun by father Gobien, called "Des Lettres Edifiantes," in 18 vols; and published some Latin poems and orations. He died in 1743.

HALDENSLEBEN, a town of Germany, in Lower Saxony, 12 miles N. of Magdeburgh.

HALE, SIR MATTHEW, lord chief justice of the King's Bench in the reign of Charles II. was the son of Robert Hale, Esq. a barrister of Lincoln's Inn, and was born in 1609. He was educated at Oxford, where he made a considerable progress in learning; but was afterwards diverted from his studies by the levities of youth.

youth. From these he was reformed by Mr. John Glanville, sergeant at law; and applying to the study of the law, entered into Lincoln's Inn. Noy, the attorney general, and Mr. Selden took much notice of him. During the civil wars, he behaved so well as to gain the esteem of both parties. He was employed in his practice by the king's party; and was appointed by the parliament one of the commissioners to treat with the king. King Charles's death gave him very sensible regret. However, he took the engagement; and was appointed with several others, to consider of the reformation of the law. In 1653, he was by writ made sergeant at law, and soon after appointed one of the justices of the Common Pleas. Upon the death of Oliver Cromwell, he refused to accept of the new commission offered him by Richard his successor. He was returned for Gloucestershire in the parliament which called home Charles II. Soon after he was made lord chief baron of the exchequer; but declined the honour of knighthood, till lord chancellor Hyde, sending for him upon business when the king was at his house, said, "There is your majesty's modest chief baron;" upon which he was unexpectedly knighted. He was one of the principal judges that sat in Clifford's Inn, about settling the differences between landlord and tenant, after the fire of London, in which he behaved to the satisfaction of all parties concerned. In his post of chief baron he acted with inflexible integrity. He dismissed a duke, who wished to prejudice him in favour of a cause he was to bring before him, with a proper reprimand. The duke complained of his rudeness to the king, who told him he verily believed he would have used him no better, had he gone to solicit him in his own cause. In one of his circuits, a gentleman who had a trial at the assizes sent him a buck for his table. When judge Hale therefore heard his name, he asked "if he was not the person who had sent him the venison?" and finding he was, told him, "that he could not suffer the trial to go on till he had paid him for his buck." The gentleman answered, that "he never sold his venison; and that he had done nothing to him which he did not do to every judge who had gone that circuit:" which was confirmed by several gentlemen present. The lord chief baron, however, paid for the present; upon which the gentleman withdrew the record. In 1671, he was advanced to be lord chief justice of the king's bench; but about four years after this promotion his health declining, he resigned his post in Feb. 1675-6, and died in Dec. following. This excellent man, who was an ornament to the bench, to his country, and to human nature, wrote, 1. An Essay on the Gravitation and Non-gravitation of Fluid Bodies. 2. Observations touching the Torricellian Experiment. 3. Contemplations, moral and divine. 4. The Life of Pomponius Atticus, with political and moral Reflections. 5. Observations on the Principles of natural Motion. 6. The primitive Origination of Mankind. He also left a great number of M. S. S. in Latin and English, upon various subjects; among which are, his Pleas of the Crown, since published by Mr. Emyln in two volumes folio; and his Original Institution, Power, and Jurisdiction, of Parliaments.

HALEM, or **HALEN**, a town of France, in the department of the Dyle, and late province of Austrian Brabant, 24 miles W. of Maestricht.

HALES, **STEPHEN**, D. D. and F. R. S. a celebrated divine and philosopher, born in 1677. He was the sixth son of Thomas Hales, Esq; the eldest son of Sir Robert Hales, and Mary the heiress of Richard Langley of Abbots-Wood in Hertfordshire. In 1696, he was entered at Bennet college, Cambridge; admitted a fellow in 1703, and became B. D. in 1711. He soon discovered a genius for natural philosophy. Botany was his first study, which he often prosecuted among Gogmagog hills, along with Dr. Stukeley. He also collected fossils and insects, having contrived a curious instrument for catching such of the latter as have wings. He likewise studied astronomy, chemistry, and anatomy; and invented a curious method of obtaining a representation of the lungs in lead. Having made himself acquainted with the Newtonian system, he contrived a machine for shewing the phenomena on much the same principles with that of the Orrery, afterwards made by Mr. Rowley. About 1710 he was presented to the perpetual cure of Teddington near Twickenham; afterwards to the living of Porlock in Somersetshire, which he exchanged for that of Faringdon in Hampshire. Soon after, he married Mary, the daughter and heiress of Dr. Newce. On the 13th March 1718, he was elected F. R. S. and on the 5th March, 1719, he exhibited an account of some experiments he had made on the effect of the

sun's warmth in raising the sap in trees, which procured him the thanks of the society. On the 14th of June 1725, he exhibited a treatise on the same subject, which, being highly applauded by the society, he enlarged and improved; and, in April 1727, published it under the title of Vegetable Statics. This work he dedicated to the prince of Wales; afterwards K. George II.; and he was the same year chosen one of the council of the Royal Society. A second edition of this work was published in 1731; in the preface to which, he promised a sequel, which he published in 1733 under the title of Statical Essays, &c. In 1732 he was appointed one of the trustees for establishing a new colony in Georgia. On the 5th of July 1733, the university of Oxford made him D. D. although he had been educated at Cambridge. In 1734, he published anonymously, A friendly Admonition to the Drinkers of Brandy and other spirituous Liquors; and a sermon preached at St. Bride's before the rest of the trustees for establishing the colony in Georgia. His text was in Gal. vi. 2. In 1739, he printed Philosophical Experiments on Sea-water, Corn, Flesh, and other Substances; 8vo. dedicated to the lords of the admiralty. In 1739, he also exhibited to the Society an account of some experiments towards the discovery of medicines, for dissolving the stone in the kidneys and bladder, and preserving meat in long voyages; for which he received Sir Godfrey Copley's gold-medal. In 1740, he published some account of Experiments and Observations on Mrs. Stephens's Medicines for dissolving the Stone, in which their dissolvent power is enquired into and demonstrated. In 1741, he read before the Society an account of a Ventilator, for conveying fresh air into mines, hospitals, prisons, and the close parts of ships. See **AIR-PIPE**, and **VENTILATOR**. He made besides these numerous and important communications to the Philosophical Transactions and Gentleman's Magazine.

HALESIA, in botany, a genus of the monogynia order, and dodecandria class of plants; natural order, Bicomnes. Calyx quadricdentate, superior; corolla quadrid; nut quadrangular and dispersuous. It has two species.

HALESWORTH, a town of Suffolk, 32 miles N. E. of Ipswich, and 101 of London.

HALF-MOON, in fortification, an outwork composed of two faces, forming a salient angle, whose gorge is in form of a crescent, whence the name. See **FORTIFICATION**.

HALICARNASSUS, in ancient geography, a principal town of Caria, built by the Argives, and situated between two bays, the Ceramicus and Jasius. It was anciently called Zephyra, and was the royal residence of Mausolus. See **ARTEMISTA**.

HALIEUTICA, or **HALIEUTICS**, [**ΑΛΙΕΥΤΙΚΑ**, formed of **αλις**, fisherman, from **αλς**, sea,] books treating of fishes, or the art of fishing. The halieutics of Oppian are still extant.

HALIFAX, a town in Yorkshire on the Calder, among hills, 16 miles S. W. of Leeds.

HALIFAX, the capital of Nova Scotia. It was founded in 1749, to secure the British settlements from the French and Indians. Lon 63. 36. W. Lat. 44. 44. N.

HALIFAX BAY, a bay on the E. coast of Hispaniola. Lon. 61. 20. W. Lat. 15. 40. N.

HALIOTIS, the **EAR-SHELL**, a genus of insects of the order vermes testacei. Animal a limax: shell univalve, dilated, ear-shaped, with a longitudinal row of orifices along the surface; spire lateral, and almost concealed. There are nineteen species. Mr. Donovan describes the H. tuberculata as a native of this country. The shell is subovate, the outside transversely grooved, rugged, and tuberculate, the inside is like mother-of-pearl. See Plate LXVII.

HALITZ, or **HALITZCH**, a town and territory of Poland, in Red Russia, 58 miles S. E. of Lemberg.

HALKETSTEIN, a town of Batavia in the department of the Rhine, and late province of Guelderland; 10 miles S. of Harderwyck.

HALL, **JOHN**, an English surgeon, who flourished in the reign of Q. Elizabeth, at Maidstone in Kent. He was born in 1529, and published; 1. A Compendium of Anatomy; and, 2. A Collection of Hymns, with musical Notes, in 1565: besides several tracts on medicine and surgery.

HALL, **JOSEPH**, an eminent English prelate, born at Ashby de la Zouch, in 1574, and educated at Cambridge. He became professor of rhetoric in that university, and was made rector of Halsted, prebendary of Wolverhampton, dean of Worcester, Bishop of

of Exeter, and lastly of Norwich. His works testify his zeal against Popery, and are much esteemed. He lamented the divisions of the Protestants, and wrote on the means of putting an end to them. In July 1616, he attended lord Doncaster into France, and upon his return was appointed by K. James one of the divines who should attend him into Scotland. In 1618 he was sent to the synod of Dort, and appointed to preach a Latin sermon before that assembly. Being obliged to return before the synod broke up, on account of his health, he was by the states presented with a gold-medal. He wrote, 1. Miscellaneous Epistles. 2. *Mundus alter et idem*. 3. A just Censure of Travellers. 4. The Christian Seneca. 5. Satires, in six books. 6. A Century of Meditations; and many other works, which, besides the satires, make 5 vols. in folio and 4to. He died in 1656.

HALL, [*hal*, Saxon; *halle*, Dutch,] in architecture, a large room at the entrance of a fine house and palace.

HALL is also a public building or court of justice, as Westminster-hall, Guild-hall, a company's hall, &c. In Westminster-hall are held the Courts of King's Bench, Common Pleas, Chancery, and Exchequer.

HALL, or HALLE, an imperial town of Germany, in Suabia, 46 miles S. E. of Heidelberg.

HALL, or HALLE, a town of Tirol, on the Inn, famous for its salt-works, 6 miles E. of Inspruck.

HALLACHORES, an unfortunate tribe in the East Indies, destined to misery from their birth, and termed the refuse of all tribes. They are held in such abomination, that, on the Malabar side of Hindostan, if one of them chance to touch a Hindoo of superior rank, the latter draws his sabre and cuts him down on the spot, without any check, either from his own conscience, or the laws of the country.

HALLAN, a province of Sweden, in the island of Schonen. Helmstadt is the capital.

HALLATON, a town of Leicestershire, seated on a rich soil, 12 miles S. E. of Leicester, and 90 N. by E. of London.

HALLE, a town of France, in the department of Gemappes, and late province of Austrian Hainault.

HALLE, a town in Upper Saxony, 56 miles S. of Magdeburg.

HALLEIN, a town in Bavaria. Lon. 12. 15. E. Lat. 47. 33. N.

HALLELUJAH, [הללויה] a term of rejoicing, first introduced into the church-service, by St. Jerome, from the synagogue. It occurs in several of the Psalms, particularly from Ps. cxlv. to cl. It also occurs in Rev. xix. 1, 3, 4, 6. For a considerable time it was only used once a year in the Latin church, viz. at Easter; but in the Greek church it was much more frequent.

HALLER, ALBERT VAN, an eminent physician, born at Bern, on the 16th Oct. 1708. He was the son of an advocate and the youngest of five. He very early shewed a great genius for literature, but it is surprising that it was not crushed in the bud, for his tutor, Abraham Billod, was such a tyrant, that the accidental sight of him, at any after period of life, excited in Haller almost all his former terrors. Yet the progress of Haller's studies was rapid almost beyond belief. When other children were beginning only to read, he was studying Bayle and Moreri; and at nine, he was able to translate Greek, and beginning to study Hebrew. His poetical essays, published in the German language, were read and admired throughout the empire. In his 16th year, he began to study medicine at Tubingen, under Duvernoy and Camerarius; and continued there for two years, when the great reputation of Boerhaave drew him to Leyden. Here he prosecuted his studies with great applause. From Holland, in 1727, he came to England, where he was honoured with the friendship of Douglas, Cheselden, and Sir Hans Sloane, P. R. S. He next went to France: where, under Winslow and Le Dran, he had new opportunities of prosecuting anatomy. But his zeal was greater than popular prejudice, even in the enlightened city of Paris, could admit of. An information being lodged against him for dissecting dead bodies, he was obliged to make a precipitate retreat to Basil, where he became a pupil to the celebrated Bernoulli. Thus improved by the most distinguished teachers of that period, and endued with uncommon natural abilities, he returned to Bern, in his 26th year, where he stood-candidate, first for the office of physician to an hospital, and afterwards for a professorship. But he was disappointed in both; and it was even with difficulty that he obtained the appointment of

keeper of a public library at Bern. This office, though by no means suited to his great abilities, afforded him an opportunity for that extensive reading by which he has been so justly distinguished. The neglect of his merit neither diminished his ardour for medical pursuits, nor detracted from his reputation at home or abroad. Soon after he was nominated a professor in the university of Gottingen, by king George II. The duties of this important office he discharged, with honour to himself and advantage to the public, for 17 years. Impressed with the great diversity of opinions respecting the æconomy of the human body, and sensible that the only means of investigating truth, was by careful experiments, he undertook the arduous task of exploring the phenomena of the human fabric; and there was hardly any function of the body on which his experiments did not reflect either a new or a stronger light. Nor was it long necessary for him, in this arduous undertaking, to labour alone. The example of the preceptor was followed by his pupils, Zinn, Zimmerman, Caldani, and many others; laboured to complete the discoveries of their great master. The mutual exertions of the teacher and his students, not only forwarded the progress of medical science, but placed the philosophy of the human body on a more sure, and an almost entirely new, basis. But the labours of Dr. Haller, during his residence at Gottingen, were not confined to one department of science. To him, the Anatomical Theatre, the School of Midwifery, the Chirurgical Society, and Royal Academy of Sciences at Gottingen, owe their origin. Such distinguished merit could not fail to meet with a suitable reward. K. George II. not only honoured him with every mark of attention himself, but procured him letters of nobility from the emperor. On the death of Dillenius, he had an offer of the professorship of botany at Oxford; the States of Holland invited him to the chair of the younger Albinus, and the K. of Prussia was anxious that he should be the successor of Maupertuis at Berlin. Marshal Keith wrote to him in the name of his sovereign, offering him the chancellorship of the university of Halle. Count Orlov invited him to Russia, in the name of the empress, offering him a distinguished place at St. Petersburg. The king of Sweden conferred on him an unsolicited honour, by raising him to the rank of knight of the polar stars, and the emperor of Germany honoured him with a personal visit; during which he passed some time with him in the most familiar conversation. Thus honoured and esteemed, he had it in his power to have held the highest rank in the republic of letters. Yet, declining all the offers made to him, he continued at Gottingen, anxious to extend the rising fame of that medical school. But after 17 years residence in that university, an ill state of health rendering him less fit for the important office which he held, he obtained permission from the regency of Hanover to return to Bern. His fellow-citizens were now as sensible as others of his superior merit. A pension was settled upon him for life, and he was elected into the most important offices in the state. These occupations, however, did not diminish his ardour for useful improvements. He was the first president, as well as the greatest promoter, of the Oeconomical Society at Bern; and he may be considered as the founder of the Orphan Hospital there. Declining health, however, restrained his exertions: and for many years he was confined entirely to his own house; where, with indefatigable industry, he continued to write till within a few days of his death: which happened in his 70th year, on the 12th Dec. 1777. His *Elementa Physiologiae* and *Bibliotheca Medicinæ*, afford undeniable proofs of his penetrating genius, and solid judgement. But he was not less distinguished as a philosopher than beloved as a man; and he was not more eminent for his improvement in every department of medical science, than for his piety to God, and benevolence to mankind.

HALLERIA, AFRICAN FLY HONEYSUCKLE; in botany, a genus of the angiospermia order, and didynamia class of plants; natural order, Personate. Calyx trifid; corolla quadrifid; filaments longer than the corolla; berry inferior and bilocular. The only species is *H. lucida*, a Cape plant.

HALLEY, Dr. EDMUND, an eminent astronomer, was the only son of a soap-boiler in London, and was born in 1656. He first studied the languages and sciences, but at length devoted himself entirely to astronomy. In 1677, he went to the island of St. Helena to complete the catalogue of fixed stars, by the addition of those which lie near the S. pole; and having delineated a planisphere

phere, in which he laid them all down in their exact places, he returned to England in 1678. In 1680 he took a tour through Europe, accompanied by the celebrated Mr. Nelson. Between Calais and Paris, he had a sight of the famous comet in its return from the sun. He had in November before seen it in its descent; and now hastened to complete his observations upon it, from the royal observatory of France. His design in this part of his tour was to settle a correspondence between the royal astronomers of Greenwich and Paris; and to improve himself under the great Cassini. He went thence to Italy, where he spent great part of 1681; but his affairs calling him home, he returned to England. In 1683; he published his "Theory of the Variation of the Magnetical Compass;" in which he supposes the globe to be a great magnet, with four magnetical poles, or points of attraction: but afterwards thinking that this theory was liable to great exceptions, he procured an application to be made to king William, who appointed him commander of the Paramour Pink, with orders to seek by observations the discovery of the rule of variations, and to lay down the longitudes and latitudes of his majesty's settlements in America. He set out on this attempt on the 24th Nov. 1698; but having crossed the line, his men grew sickly; and his lieutenant mutinying, he returned home in June 1699. Having got the lieutenant tried and cashiered, he sailed a second time in Sept. following, with the same ship, and another of less bulk, of which he had also the command. He now traversed the vast Atlantic from one hemisphere to the other, as far as the ice would permit him; and having made observations at St. Helena, Brazil, Cape Verd, Barbadoes, the Madeiras, the Canaries, the coast of Barbary, and many other latitudes, arrived in Sept. 1700; and published a general chart, in 1701, shewing at one view the variation of the compass in all those places. Capt. Halley had been at home little more than half a year, when he was sent by the king, to observe the course of the tides, with the longitude and latitude of the principal head-lands in the British channel; which having executed with his usual accuracy, he published a large map of the Channel. Soon after, the Emperor of Germany resolving to make a convenient harbour for shipping in the Adriatic, Capt. Halley was sent by queen Anne to view the two ports on the coast of Dalmatia. He embarked on the 22d Nov. 1702; passed over to Holland; and going through Germany to Vienna, he proceeded to Istria; but the Dutch opposing the design, it was laid aside. The emperor made him a present of a rich diamond-ring from his finger, and honoured him with a letter of recommendation; written with his own hand, to queen Anne. Soon after his return, he was sent again on the same business; when passing through Hanover, he supped with the electoral prince, afterwards king George I. and his sister the queen of Prussia. On his arrival at Vienna, he was the same evening presented to the emperor, who sent his engineer to attend him to Istria, where they repaired and added new fortifications to those of Trieste. Mr. Halley returned to England in 1703; was made professor of geometry in the university of Oxford, and received the degree of L. L. D. He was scarcely settled at Oxford, when he began to translate into Latin from the Arabic, "Apollonius de Sectione Rationis;" and to restore Apollonius's books "De Sectione Spatii," from the account given of them by Pappus; and he published the whole work in 1706. Afterwards he had a share in preparing for the press Apollonius's Conics; and ventured to supply the whole 8th book, the original of which is also lost. He likewise added Serenus on the Section of the Cylinder and Cone, printed from the original Greek, with a Latin translation, and published the whole in folio. In 1713, he was made secretary of the Royal Society; in 1720, king's astronomer at the royal observatory at Greenwich; and, in 1729, a member of the Academy of Sciences at Paris. He died at Greenwich in 1742. His principal works are, 1. *Catalogus Stellarum Austrarium*. 2. *Tabula Astronomica*. 3. An Abridgement of the Astronomy of Comets, &c. He also published several works of Sir Isaac Newton; who had a particular friendship for him, and to whom he frequently communicated his discoveries.

HALLEY'S QUADRANT. See QUADRANT.

HALLIARDS, [corrupted from *haul* and *yard*,] the ropes or tackles usually employed to hoist or lower any sail upon its respective mast or stay. See JEARS.

HALMOTÉ, or HALIMOTÉ, the same with Court-Baron, the word implying a meeting of the tenant of the same hall or manor.

HALO, or CORONA, in optics and meteorology, luminous circle, surrounding the sun, moon, planets, or fixed stars. Sometimes these circles are white, and sometimes coloured, like the rainbow. Sometimes one only is visible, and sometimes several concentric halos appear at the same time. Those which have been seen about Sirius and Jupiter were never more than 3°, 4°, or 5°; in diameter; those which surround the moon are, also, sometimes no more than 3° or 5°; but these, as well as those which surround the sun, are of very different magnitudes, viz. of 12° 0', 22° 35', 30° 0', 38° 0', 41° 2', 46° 24', 47° 0', and 90°, or even larger than this. Their diameters also sometimes vary during the time of observation, and the breadths both of the coloured and white circles are very different, viz. of two, four, or seven degrees. Their colours are more diluted than those of the rainbow; and they are in a different order, according to their size. Mr. Huygens observed red next the sun, and a pale blue outwards. Sometimes they are red on the inside and white on the outside. M. Weidler observed one that was yellow on the inside and white on the outside. In France, one was observed in 1683, the middle of which was white; after which followed a border of red, next to it was blue, then green, and the outermost circle was a bright red. In 1728, one was seen of a pale red outwardly, then followed yellow, and then green, terminated by a white. In Holland, M. Muschenbroeck says, 50 may be seen in the day-time, almost every day; but they are difficult to be observed, except the eye be so situated, that not the body of the sun, but only the neighbouring parts of the heavens can be seen. Mr. Middleton says, that this phenomenon is very frequent in North America; for that there is generally one or two about the sun every week, and as many about the moon every month. Halos round the sun are very frequent in Russia. M. Épinus says, that from the 23d April 1758, to the 20th Sept. he himself had observed no less than 26, and that he has sometimes seen twice as many in the same space of time.

HALOS, ARTIFICIAL. Halos may be produced by placing a lighted candle in the midst of steam in cold weather. If glass-windows be breathed upon, and the flame of a candle be placed some feet from it, while the spectator is also at the distance of some feet from another part of a window, the flame will be surrounded with a coloured halo. And if a candle be placed behind a glass receiver, when air is admitted into the vacuum within it, a certain degree of density, the vapour with which it is loaded will make a coloured halo round the flame. This was observed by Otto Guericke. In Dec. 1756, M. Muschenbroeck observed, that when the glass-windows of his room were covered with a thin plate of ice on the inside, the moon appearing through it was surrounded with a large and variously coloured halo; and, opening the window, he found that it arose intirely from that thin plate of ice; for none was seen except through it. Dr. Kotelnikow, having, like Dr. Halley, made very accurate observations to determine the number of possible rainbows, considers the coloured halo which appears about a candle as the same thing with one of these bows which is formed near the body of the sun, but which is not visible on account of his excessive splendor.

HALOS, DESCARTES AND GASSENDI'S HYPOTHESES OF. M. Descartes observes, that the halo never appears when it rains: from which he concludes that this phenomenon is occasioned by the refraction of light in the round particles of ice, which are then floating in the atmosphere; and though these particles are flat when they fall to the ground, he thought they must be protuberant in the middle, before their descent; and according to this protuberancy he imagined that the diameter of the halo would vary. In treating of meteors, Gassendi supposed, that a halo is of the same nature with the rainbow, the rays of light being in both cases twice refracted and once reflected within each drop of rain or vapour, and that all the difference there is between them arises from their different situation with respect to the observer. For, whereas, when the sun is behind the spectator, and consequently the rainbow before him, his eye is in the centre of the circle: when he views the halo, with his face toward the sun, his eye is in the circumference of the circle; so that according to the known principles of geometry, the angle, under which the object appears in this case, must be just half of what it is in the other.

HALOS, EXPERIMENTS AND THEORY OF DECHALES RESPECTING. M. Dechales endeavours to shew that the generation of the halo is similar to that of the rainbow. If, says he, a sphere of glass or crystal, AB, Plate LXXVIII. fig. 12, full of water, be placed in

in the beams of the sun shining from C, there will not only be two circles of coloured light on the side next the sun, and which constitute the two rainbows; but there will also be another on the part opposite to the sun, the rays belonging to which, meeting at E, afterwards diverge, and form the coloured circle G, as will be visible, if the light that is transmitted through the globe be received on a piece of white paper. The colours also will appear to an eye placed in any part of the surface of the cone FEG. Measuring the angle FEH, he found it to be 23 degrees. They were only the extreme rays of this cone that were coloured like those of the rainbow. This experiment he thought sufficiently illustrated the generation of the halo; so that whenever the texture of the clouds is such, as not entirely to intercept the rays of the sun or moon, and yet have some degree of density, there will always be a halo round them, the colours of the rainbow appearing in those drops which are 23° distant from the sun or moon. If the sun be at A, and the spectator in B, fig. 13, the halo will be the circle DEF, DBE being 46° or twice 23. The reason why the colours of the halo are more dilute than those of the rainbow, he says, is owing principally to their being formed not in large drops of rain, but in very small vapour; for if the drops of water were large, the cloud would be so thick, that the rays of the sun could not be regularly transmitted through them; and, on the other hand, he observed, that when the rainbow is formed by very thin vapours, the colours hardly appear. As for those circles of colours which are sometimes seen round candles, it was his opinion that they are owing to nothing but moisture on the eye of the observer; for that he could never produce this appearance by means of vapour only, if he wiped his eyes carefully; and he had observed that such circles are visible to some persons and not to others, and to the same persons at one time and not at another.

HALOS, HUYGENS'S THEORY OF. The most considerable and generally received theory, respecting halos, is that of Mr. Huygens. Sir Isaac Newton mentions it with respect, and Dr. Smith, in his complete System of Optics, does not hint at any other. M. Huygens takes it for granted that at those times there are in the atmosphere certain bodies of the figure of round balls, opaque in the centre, but covered with a transparent shell. By the help of this he endeavours to account for halos. Those bodies which M. Huygens requires, in order to explain these phenomena, are not, however, a mere assumption; for some such, though of a larger size than his purpose requires, have been actually found, consisting of snow within and ice without. They are particularly mentioned by Descartes. These things premised, he addresses himself to the solution, as follows. Let ABCD, fig. 14, represent such a globule with the opaque nucleus EF in the middle of it; and let us suppose the rays coming from G, H, to fall on the side AD. It is manifest they will be refracted inwards from the surface AD; from whence it follows that a great number of them must strike upon the kernel EF. Let GA, and HD, be the rays which, after refraction, touch the sides of the kernel EF, and let them be refracted again at B and C, emerging in the lines BK, and CK, crossing each other in the point K, whose distance from the globule is somewhat less than its semidiameter. Wherefore, if BK and CK be produced towards M and L, fig. 15, it follows that no light coming from the sun through the globule, can proceed to the eye any where placed within the angle LKM, or rather in the cone which that represents; supposing that the obliquity of the incident rays HD and GA is such as shall make the arc BC the greatest possible: for then all the rays exterior to HD and GA, will be refracted nearer to Q, and after emergence cross each other in a point k, nearer the globule than the former; and therefore cannot come at the eye placed within the said cone LKM. Suppose now the eye placed at N, fig. 15, and let NR, NQ, be drawn parallel to LK, and MK; then it is plain none of the globules, the same as ABCD, within the cone RNQ, can come to the eye at N. Thus the globules at O and P have their refracted rays ak, kc, and dk, kb, including the eye in the cone of obscurity. But other globules which lie without the cone QNR, as S and T, do not involve the eye N by their shadow-cones lkd, and fkm; and therefore some of those rays which are more refracted than kd, or kf, will fall upon the eye, and produce a luminous circular ring or corona, including a dark area within, and whose light outwardly decreases as it is more remote from the centre. To verify this hypothesis, M. Huygens advises us to expose to the sun a thin

glass-bubble, filled with water, and having some opaque substance in the centre of it; and he says we shall find, that we shall not be able to see the sun through it, unless at a certain distance from a place opposite to the centre of it: but as soon as we do perceive the light, the image of the sun will immediately appear the brightest, and coloured red, for the same reason as in the rainbow. These halos, he says, often appear about the moon; but the colours are so weak as to appear only white. Such white coronas he had also seen about the sun, when the space within them appeared scarce darker than that without. This he supposes to happen when there are but few of those globules in the atmosphere; for the more plentiful they are, the more lively the colours of the halo appear; at the same time also the area within the corona will be the darker. The apparent diameter of the corona, which is generally about 45° , depends upon the size of the darker kernel; for the larger it is with respect to the whole globule, the larger will be the dark cone behind it. The globules that form these halos, Huygens supposes to have consisted of soft snow, and to have been rounded by continual agitation in the air, and thawed on the outsides by the heat of the sun. In order to make the diameter of the halo 45° he demonstrates that the semidiameter of the globule must be to the semidiameter of the kernel of snow very nearly as 1000 to 480, and that to make a corona of 100° it must be as 1000 to 680.

HALOS, SIR ISAAC NEWTON'S THEORY OF. This great philosopher considered the larger and less variable appearances of this kind as produced according to the common laws of refraction, but that the less and more variable appearances depend upon the same cause with the colours of thin plates. He concludes his explication of the rainbow with the following observation on halos and parhelia. "The light which comes through drops of rain by two refractions, without any reflexion, ought to appear the strongest at the distance of about 26° from the sun, and to decay gradually both ways as the distance from him increases. And the same is to be understood of light transmitted through spherical hail-stones: and if the hail be a little flattened, as it often is, the transmitted light may be so strong, at a little less distance than that of 26° as to form a halo about the sun or moon; which halo, as often as the hail-stones are duly figured, may be coloured, and then it must be red within by the least refrangible rays, and blue without by the most refrangible ones; especially if the hail-stones have opaque globules of snow in their centres to intercept the light within the halo, as Huygens has observed, and make the inside of it more distinctly defined than it would otherwise be. For such hail-stones, though spherical, by terminating the light by the snow, may make a halo red within, and colourless without, and darker within the red than without, as halos use to be. For of those rays which pass close by the snow, the red-making ones will be the least refracted, and to come to the eye in the straightest lines."

HALOS, WEIDLER'S THEORY OF. Mr. Weidler, in his "Commentary on Parhelia," published at Wirtemberg in 1733, observes that it is very improbable that such globules as Mr. Huygens's hypothesis requires, with nuclei of such a precise proportion, should exist; and if there were such bodies, he thinks they would be too small to produce the effects ascribed to them. Besides, he observes that appearances exactly similar to halos are not uncommon, where fluid vapours alone are concerned; as when a candle is placed behind the steam of boiling water in frosty weather, or in the midst of the vapour issuing copiously from a bath, or behind a receiver when the air is so much rarefied as to be incapable of supporting the water it contains. The rays of the sun twice reflected and twice refracted within small drops of water are sufficient, he says, without any opaque kernel, to produce all the appearances of the halos that have the red light towards the sun, as may be proved by experiment. That the diameter of the halos is generally half of that of the rainbow, he accounts for as Gassendi did before him.

HALORAGUS, in botany, a genus of the tetragynia order, and octandria class of plants. Calyx four-cleft, superior; petals four; drupe dry, inclosing a four-celled nut. There are two species, viz. *H. prostrata* and *H. cercodia*.

HALSTEAD, a town of Essex, 47 miles N. E. of London.

HALTER, [*ἅλτης*, Gr. *halter*, Latin,] a peculiar kind of discus. See *DISC*, *DISCUS*, and *HALTERISTÆ*.

HALTER, in the manege, a head-stall for a horse.

HALTER-CAST, is an excoriation of the pastern, occasioned by the halter's being entangled about a horse's foot, upon his endeavouring to rub his neck with his hinder feet. For the cure, anoint the place morning and evening, with equal quantities of lintseed-oil and brandy, well mixed.

HALTEREN, a town of Germany, 20 miles S. W. of Munster.

HALTERISTÆ, in antiquity, a kind of players at Discus. Some take the discus to have been a leaden weight or ball, which the vaulters bore in their hands, to secure and keep themselves the more steady in their leaping. Others say the halter was a lump of lead or stone, with a hole, or handle fixed to it, by which it might be carried.

HALTON, or HAULTON, *i. e.* High-Town, a town of Cheshire, 13 miles N. E. of Chester, and 186 N. W. of London.

HALTWEZEL, or HALTWHISTLE, a well-built town of England, in Northumberland, on the South Tyne, 37 miles W. of Newcastle, and 314 N. W. of London.

HALYMOTE, properly signifies holy or ecclesiastical court. See HALMOTE. It was anciently held on Sunday before St. Thomas's day, and hence called the Haly Mote or Holy Court.

HALYS, in ancient geography, the noblest river of the Hither Asia, through which it has a long course, was the boundary of Cræsus's kingdom on the east. It separated Paphlagonia from Cappadocia; and received its name *απο του αλως*, from salt, because its waters were of a salt taste; from the soil over which they flowed. It is famous for the defeat of Cræsus king of Lydia, who was misled by this ambiguous response of the oracle; *Χραιοος Αλυν διαδας μεγαλην αρχην διαλυσει*; *i. e.* If Cræsus passes over the Halys he shall destroy a great empire. That empire proved to be his own.

HALYWERCFOLE, anciently persons who enjoyed land, by the pious service of repairing some church, or defending a sepulchre. It also signified persons in the diocese of Durham, who held their lands to defend the corpse of St. Cuthbert, and thence claimed the privilege of not being forced to go out of the bishopric.

HAM, [חם, Heb. *i. e.* crafty,] the youngest son of Noah, and father of Cush, Mizraim, Phut, and Canaan; each of whom possessed the countries peopled by them. Ham, it is believed, had all Africa for his inheritance, and peopled it with his posterity. He himself, it is thought, dwelt in Egypt, but M. Basnage is of opinion, that neither Ham nor Mizraim ever were in Egypt, but that their posterity settled in this country, and called it by the name of their ancestor. He also doubts of his having been worshipped as a god, by the name of Jupiter Hammon. Be that as it may, Africa is called the Land of Ham, in Psalm lxxviii. 51, cv. 23, cvi. 22. In Plutarch, Egypt is called Chemia; and there are traces of the name of Ham or Cham, in Pschemmis, and Psitta chemnis, which are cantons of Egypt. See EGYPT.

HAM, [*ham*, Saxon; *hamme*, Dutch,] the hip; the hinder part of the articulation of the thigh with the knee.

HAM, in commerce, &c. the thigh of a hog salted. Westphalia hams are prepared by salting them with saltpetre, pressing them in a press eight or ten days, then steeping them in juniper-water, and drying them by the smoke of juniper-wood. A ham may be salted in imitation of those of Westphalia, by sprinkling a ham of young pork with salt for one day, to fetch out the blood; then wiping it dry, and rubbing it with a mixture of a pound of brown sugar, a quarter of a pound of saltpetre, half a pint of bay-salt, and three pints of common salt, well stirred in an iron pan over the fire, till moderately hot: let it lie three weeks in this salting; turn it often; and dry it and hang it up.

HAM, in names, whether initial or final, is no other than the Saxon *ham*, a house, farm, or village. Gibson's Camden.

* HAM signifies also a narrow meadow.

HAM, or HAMM, a city in the kingdom of Westphalia. Lon. 7. 53. E. Lat. 51. 42. N.

HAM, a town of France, in the department of Somme, and late province of Picardy, 10 miles N. of Noyons, and 43 of Paris.

HAMADRYADES, [from *αμα*, together, and *δρυς*, an oak,] a kind of inferior deities revered among the ancient heathens, and believed to preside over woods and forests, and to be inclosed un-

der the bark of oaks. They were supposed to live and die with the trees they were attached to; as is observed by Servius on Virgil, Eclog. x. ver. 62. This idea among the ancients, of intellectual beings annexed to trees, accounts for their worship of trees.

HAMAH, a town of Asiatic Turkey, in Syria. By some travellers it is corruptly called Amari and Amant. Some mistake it for the ancient Apamea. Linen is manufactured there, and sent to Tripoli to be exported into Europe. Lon. 36. 15. E. Lat. 35. 15. N.

HAMAMELIS, WITCH-HAZEL, a genus of the digynia order, and tetrandria class of plants. Involucre three-leaved; perianthers four-leaved; petals four; nut two-horned, two-celled. There is only one species, viz. *H. virginica*.

HAMAMET, a town of Barbary, on the E. coast of Tunis, 30 miles S. of Tunis.

HAMAMLEEF, a town 12 miles E. of Tunis, noted for its hot-baths, which are famed for curing rheumatisms and many other complaints. The Bey has a very fine bath, which he permits the consuls and others to use.

HAMAN, [חמן, Heb. *i. e.* making an uproar,] the son of Hammedatha, an Agagite, or Amalekite, the prime-minister of Persia and favourite of King Ahasuerus; was one of the most barbarous and vindictive monsters that ever existed, who, to gratify his haughty vengeance against a single individual, planned the massacre of the whole nation of the Jews. His diabolical scheme, repeated disappointments, and deserved death, are recorded in Esther, ch. iii. vi. and vii.

HAMAR, a town of Norway, in Aggerhuys, 52 miles N. E. of Christiana.

HAMAXOBIANS, HAMAXOBI, or HAMAXOBIÆ, [from *μάχη*, a chariot, and *βίος*, life,] a people who had no houses, but lived in carriages. They were an ancient people of Sarmatia Europæa, inhabiting the southern part of Muscovy, and instead of houses had a sort of tents made of leather, fixed on carriages to be ready for travelling.

HAMBURG, or HAMBURGH, a late imperial city of Germany. Its name is derived from the old German word *Hamme*, signifying a wood, and *Burg*, a castle; and stands on the N. side of Elbe, where it is four miles broad, and forms two spacious harbours. It also runs through most part of it in canals. It lies 38 miles S. W. of Lubec, and 58 N. E. of Bremen. Lon. 9. 55. E. Lat. 53. 35. N.

HAME, [*hama*, Sax.] the collar by which a horse draws in a waggon.

HAMEL, JOHN BAPTISTE DU, a learned French philosopher of the 17th century. At eighteen he wrote a treatise, in which he explained in a very simple manner Theodosius's three books of Spherics; to which he added a tract upon trigonometry; extremely perspicuous, and designed as an introduction to astronomy. Natural philosophy, as then taught, was only a collection of vague, knotty, and barren questions; when he undertook to establish it upon right principles, and published his "*Astronomia Physica*." In 1666, Mr. Colbert proposed to Lewis XIV. a scheme for establishing a royal academy of sciences; and appointed Du Hamel secretary. He was also regius professor of philosophy, and published a great number of books. He died at Paris in 1706, aged 83. He wrote Latin with purity and elegance.

HAMELBURG, a town of Franconia, in Fulda, on the Saab, 16 miles S. of Schweinfurt, 24 S. of Fulda.

HAMELIN, or HAMELN, a town in Lower Saxony, 18 miles S. E. of Minden, and 28 S. W. of Hanover.

HAMELLIA, in botany, a genus of the monogynia order, and pentandria class of plants. Corolla quinquefid; berry quinquelocular, inferior, polyspermous. It has four species, natives of the West Indies.

HAMI, a country of Asia, subject to the Chinese, situated N. E. of China, at the extremity of that desert which the Chinese call Chamô, and the Tartars Cobi; 90 leagues distant from the most westerly point of the province of Chensi.

HAMI, the capital of the above kingdom, is surrounded by lofty walls, half a league in circumference.

HAMILTON, a town of Scotland in Lanarkshire, 11 miles S. E. of Glasgow.

HAMLET, a prince of Denmark, whose history has been rendered

dered interesting, by being the subject of one of the noblest tragedies of Shakespeare. Adjoining to a royal palace, which stands about half a mile from Cronburg in Elsinour, is a garden, which, Mr. Coxe informs us, is called Hamlet's Garden, and is said to be the spot where his father was murdered. The house is of modern date, and is situated at the foot of a sandy ridge near the sea. The garden occupies the side of the hill, and is laid out in terraces rising above each other. The original history, from which the poet derived the principal incidents of his play, is founded upon facts, but so deeply buried in remote antiquity that it is difficult to discriminate truth from fable. Saxo-Græmmaticus, who flourished in the 12th century, is the earliest historian of Denmark who relates the adventures of Hamlet. His account is much altered, by Belleforest, a French author, a translation of whose romance was published under the title of "The History of Hamlet;" from which Shakespeare formed the ground-work of his play.

HAMLET, HAMEL, or HAMSEL, was formerly used for part of a village or parish. Spelman makes a difference between villam integram, villam dimidiam, and hamletam; and Stow expounds it to be the seat of a freeholder. Several county towns have hamlets.

HAMMER, [*hamer*, Saxon; *hammer*, Danish,] a well known tool used by mechanics, consisting of an iron-head fixed crosswise upon a handle of wood. There are several sorts of hammers used by blacksmiths; as, 1. The hand-hammer, which is of such weight that it may be wielded with one hand at the anvil. 2. The up-hand sledge-hammer used with both hands, and seldom lifted above the head. 3. The about sledge-hammer, which is the biggest of all, and held by both hands at the farthest end of the handle; and being swung at arms-length over the head, is made to fall upon the work with as heavy a blow as possible. The smallest hammer used by smiths is called a rivetting-hammer, but is seldom used at the forge unless upon small work.

HAMMERING, in coining. A piece of money or a medal is said to be hammered, when the impression is given with a hammer and not with a mill.

HAMMERMEN, in the polity of the royal boroughs of Scotland, the name of an incorporation, which comprehends most of those artificers who make use of hammers; such as goldsmiths, jewellers, watch-makers, coppersmiths, braziers, blacksmiths, tin-plate workers, cutlers, gun-smiths, founders, saddlers, &c.

HAMMOCK, [*hamaca*, Saxon,] swinging-beds for seamen to sleep in. They are suspended between two trees, posts, hooks, or the like, and are much used throughout the West Indies, as well as on board of ships. The Indians hang their hammocks on trees, to secure themselves from wild beasts and insects.

HAMONT, or HELMONT, a town of France, in the department of the Lower Meuse, and late bishopric of Liege, 17 miles W. of Ruremond.

HAMPDEN, JOHN, Esq. of Hamden, a celebrated patriot, descended of an ancient family in Buckinghamshire, was born at London in 1594. He was cousin-german to Oliver Cromwell, his mother being Oliver's aunt. In 1609 he was sent to Magdalen College, Oxford, whence he went to the inns of court, where he made a considerable progress in the law. He was elected a member of the parliament, which began at Westminster, Feb. 5, 1626; and served in all the succeeding parliaments in the reign of Charles I. In 1636 he became universally known, by his refusal to pay shipmoney, as being an illegal tax; upon which he was prosecuted, and his conduct throughout this transaction gained him a great character. When the long parliament began, the eyes of all men were fixed on him as their pater patriæ. On January 3, 1644, the king ordered articles of high treason and other misdemeanours to be prepared against Lord Kimbolton, Mr. Hampden, and four other members of the House of Commons, and went to that house to seize them: but they had retired. Mr. Hampden afterwards made a speech in the house to clear himself of the charge laid against him. In the beginning of the civil war he commanded a regiment of foot, and was of great service to the parliament at the battle of Edge-hill. He received a mortal wound in the shoulder in an engagement with Prince Rupert, on the 18th of June 1643, at Chalgravefield in Oxfordshire; and died on the 24th. He had the art of Socrates, of interrogating, and under the pretence of doubts, insinuating objections, so that he

infused his own opinions into those from whom he appeared to learn them.

HAMPSHIRE, or HANTS, or SOUTHAMPTON, a county of England, bounded on the N. by Berkshire. It extends 55 miles in length from N. to S. 40 in breadth from E. to W. and is about 220 miles in circumference. The air is very pure, especially upon the downs, on which vast flocks of sheep are kept and bred. In the champaign-part of the county, the soil is very fertile, producing all kinds of grain. The rivers are the Avon, Anton, Arle, Test, Stour, and Itchen; besides several smaller streams, all abounding in fish.

HAMPSHIRE, New, one of the United States of North America, bounded on the N. by Lower Canada. It lies between 2° 41' and 4° 29' Lon. E. of Philadelphia; and between 42° 41' and 45° 30' Lat. N.

HAMPTON, a town of Middlesex, on the Thames, 15 miles W. S. W. of London, and two from Richmond and Kingstown. It is chiefly famous for its royal palace, called Hampton Court, which is the finest in Britain.

HAMPTON, a sea-port of Virginia, 18 miles S. E. of York-Town, and 371 S. S. W. of Philadelphia.

HANAPER, or HAMPER, an office in chancery, under the direction of a master, his deputy, and clerks, comptroller, &c. answering, in some measure, to the fiscus among the Romans.

HANAPER, THE CLERK or WARDEN OF THE, receives also all money due for commissions, and writs; and attends the keeper of the seal daily in term time, and at term-time of sealing; and takes into his custody all sealed charters, patents, &c. which he receives into bags, but anciently, it is supposed, into hampers, which gave name to the office.

HANAU, or HANAU MUNZENBERG, a late county of Germany, bounded by the electorate of Mentz, the bishopric of Fulda, the lordships of Reineck, and Solms; the territories of Hesse-Homburgh, Friedburgh, and Frankfort. Its length was 45 miles; its greatest breadth not above 15. It is very fertile in corn, wine, and fruits; and has salt-springs, with mines of copper, silver, and cobalt. The chief rivers are the Mayne, the Kinzig, and the Nidda. The prevailing religion is Calvinism, but Lutherans and Catholics are tolerated. The chief towns are Hanau, Bergen, Stenau, and Glenhausen.

HANAU, the capital of the above county, eight miles east of Frankfort.

HANAZO, a river of Abyssinia.

HANBOROUGH, two villages in Oxfordshire.

HANCES, in architecture, the ends of elliptical arches; and these are the arches of smaller circles than the scheme, or middle-part of the arch.

HANCES, in a ship, falls of the five-rails placed on bannisters on the poop and quarter-deck down to the gangway.

HANCOCK, a county of the United States in the district of Maine, bounded on the E. by Washington county.

HAND, a member of the human body, at the extremity of the arm. See ANATOMY. The mechanism of the hand is excellently fitted for the various uses and occasions we have for it, and the great number of arts and manufactures it is to be employed in. It consists of a compages of nerves, and little bones joined into each other, which give it a great degree of strength, and at the same time an unusual flexibility, to enable it to handle adjacent bodies, lay hold of them, and grasp them, in order either to draw them toward us, or thrust them off. Anaxagoras is said to have maintained that man owes all his wisdom, knowledge, and superiority over other animals, to the use of his hands. But Galen more justly remarks, that man is not the wisest creature, because he has hands; but he had hands given him because he was the wisest creature; for it was not our hands that taught us arts, but our reason. The hands are the organs of reason, &c. In scripture the word hand is variously applied. To pour water on any one's hand, signifies to serve him. To wash the hands was a ceremony used to denote innocence from murder or manslaughter. To kiss the hand was an act of adoration. To fill the hand signified taking possession of the priesthood, and performing fractions. To lean upon any one's hand was a mark of familiarity and superiority. To give the hand signifies to grant peace, swear friendship, promise security, or make alliance. The right-hand was the place of honour and respect. Amongst the Greeks and Romans it was customary

customary for inferiors to walk on the left-hand of superiors, that the right-hand might be ready to afford protection and defence to their left side, which was, on account of the awkwardness of the left hand, more exposed to danger.

HAND, in falconry, is used for the foot of the hawk. To have a clean, strong, slender, glutinous hand, well clawed, are good qualities of a hawk or falcon.

HAND, in the manage, is also used for the fore-foot of a horse: also for a division of the horse into two parts, with respect to the rider's hand. The fore-hand includes the head, neck, and fore-quarters; the hind-hand is all the rest of the horse.

HAND, in painting, sculpture, &c. is figuratively used for the style of a master.

HAND is much used in composition for that which is manageable by the hand, as a handsaw; or borne in the hand, as a hand-barrow.

HANDS are borne in coat-armour, dexter and sinister; that is, right and left, expanded or open; and after other manners. A bloody hand in the centre of the escutcheon is the badge of a baronet of Great Britain.

HAND-BOROW, in law-books, a surety, or manual pledge, of an inferior rank; as head-borow signifies a chief or superior.

HAND-BREADTH, a measure of three inches. By this standard the height of horses is estimated.

HAND-CUFFS, an instrument formed of two circular pieces of iron, each fixed on a hinge on the ends of a very short iron-bar, which being locked over the wrists of a malefactor, prevents his using his hands.

HAND-SPIKES, wooden levers used at sea to traverse the ordnance, or to turn the windlass in weighing up the anchor, &c. They are more commodious than iron-crows, because their length allows a better poize.

HANDEL, GEORGE FREDERIC, a most eminent master and composer of music, born at Halle, in Upper Saxony, 24th Feb. 1684. His father was a physician in that city, and was upwards of sixty years of age when he was born. During his infancy young Handel amused himself with musical instruments, and made considerable progress before he was seven years of age, without instruction. His propensity for music at last became so strong, that his father, who designed him for the law, forbade him to touch a musical instrument. Handel however concealed a little clavi-chord in the garret, to which he constantly stole when the family were asleep: and thus made such advances in his art, as enabled him to play on the harpsichord. He was first taken notice of by the duke of Saxe Weissenfels on the following occasion. His father went to see another son by a former wife, who was valet de chambre to the duke, and took young Handel, being then in his seventh year, along with him. While he was in the duke's court, it was impossible to keep him from harpsichords; and he sometimes got into the organ-loft at church, and played after service was over. On one of these occasions, the duke happening to go out later than usual, found something so uncommon in Handel's manner of playing, that he inquired of his valet who it was; and receiving for answer that it was his brother, he desired to see him. The duke was so much taken with the musical genius shewn by young Handel, that he persuaded his father to let him follow his inclination. He made the boy a present; and told him, that if he minded his studies, no encouragement should be wanting. On his return to Halle, Handel was placed under one Zackaw, the organist of the cathedral, and was even then able to supply his master's place in his absence. At nine years of age he began to compose church-services for voices and instruments, and continued to compose one every week for three years. At fourteen, he far excelled his master, as he himself owned; and he was sent to Berlin, where he had a relation about the court, on whose care his parents could rely. The opera was then flourishing, being encouraged by Frederic I. king of Prussia, and under the direction of Buononcini, Attilio, and other eminent Italian masters. Buononcini, being of a haughty disposition, treated Handel with contempt; but Attilio behaved to him with great kindness, and he profited much by his instructions. His abilities soon recommended him to the king, who frequently made him presents. After this he went to Hamburg, where the opera was little inferior to that of Berlin. Soon after his arrival his father died; and his mother being left in narrow circumstances, he thought it necessary

to procure some scholars, and to accept a place in the orchestra; by which means, instead of being a burden, he became a great relief to her. At this time the first harpsichord in Hamburg was played by one Kefer, who also excelled in composition; but he, having involved himself in debt, was obliged to abscond. Upon this vacancy, the person who had been used to play the second harpsichord claimed the first by right of succession; but was opposed by Handel, who founded his claim upon his superior abilities. After much dispute, it was decided in favour of Handel; but his antagonist, as they were coming out of the orchestra, made a push at Handel's breast with a sword, which must undoubtedly have killed him, had there not fortunately been a music-book in the bosom of his coat. Handel, though yet but in his 15th year, became composer to the house; and the success of *Almeria*, his first opera, was so great, that it ran thirty nights without interruption. Within less than a year after this, he set two others, called *Florinda* and *Norene*, which were received with equal applause. In his 19th year, Handel took a journey to Italy, where he was received with the greatest kindness by the prince of Tuscany, as well as by the grand duke, who was impatient to have something composed by so great a master; and notwithstanding the difference between the style of the Italian music and the German, to which Handel had hitherto been accustomed, he set an opera called *Roderigo*, which pleased so well, that he was rewarded with 100 sequins and a service of plate. After staying about a year in Florence, he went to Venice, and after some time proceeded to Rome, where he became acquainted with cardinal Ottoboni and many other dignitaries, by whom he was frequently attacked on account of his religion; but Handel declared he would live and die in the religion in which he was educated. Ottoboni also contrived to have a trial of skill between him and Dominici Scarlatti. When they came to the organ, Scarlatti himself yielded the superiority to Handel. From Rome Handel went to Naples; after which he paid a second visit to Florence; and at last, having spent six years in Italy, set out for his native country. In his way thither, he was introduced at the court of Hanover by baron Kilmanseck; when the Elector, (afterwards King George I.) offered him a pension of 1500 crowns a-year as an inducement for him to continue there. This generous offer he declined on account of his having promised to visit the court of the Elector Palatine. The elector being made acquainted with this objection, generously ordered him to be told, that his acceptance of the pension should not restrain him from his promise, but that he should be at full liberty to be absent a year or more if he chose it, and to go wherever he thought fit. Soon after, the place of master of the chapel was bestowed upon Handel; and having visited his mother, who was now aged and blind, and his old master Zackaw, and staid some time at the court of the Elector Palatine, he set out for England, where he arrived in 1710. Operas were then a new entertainment in England, and were conducted in a very absurd manner; but Handel soon put them on a better footing; and set a drama called *Rinaldo*, which was performed with uncommon success. Having staid a year in England, he returned to Hanover; but in 1712 he again came over to England; and the peace of Utrecht being concluded a few months afterwards, he composed a grand *Te Deum* and *Jubilate* on the occasion. He now found the nobility very desirous that he should resume the direction of the opera-house in the Hay-Market; and queen Anne having added her authority to their solicitations, and conferred on him a pension of 200l. a-year, he remained in Britain till the death of the queen in 1714, and the accession of King George I. who added a pension of 200l. a-year to that bestowed by queen Anne; which was soon after increased to 400l. on his being appointed to teach the young princesses music. In 1715, Handel composed his opera of *Amadige*; but from that time to 1720 he composed only *Teseo* and *Pastor Fido*, *Buononcini* and *Attilio* being then composers for the operas. About this time a project was formed by the nobility for erecting a kind of Academy at the Hay-Market, to secure to themselves a constant supply of operas to be composed by Handel, and performed under his direction. No less than 50,000l. were subscribed for this scheme, of which the king subscribed 1000l. and it was proposed to continue the undertaking for fourteen years. Handel went over to Dresden, to engage singers, and returned with *Senesino* and *Duristanti*. *Buononcini* and *Attilio* had still a strong party, but not equal to that

of Handel; and therefore in 1720 he obtained leave to perform his opera of *Radamisto*. The house was so crowded, that many fainted; and 40s. were offered by some for a seat in the gallery. The contention, however, still ran very high between Handel's party and that of the two Italian masters; upon which Dean Swift with his usual acrimony wrote the following epigram:

Some say that signior Buononcini
Compar'd to Handel's a mere ninny:
Others do swear that to him Handel
Is hardly fit to hold the candle.
Strange that such high contests should be
'Twixt Tweedle-dum and Tweedle-dee!

The academy being firmly established, Handel conducted it for nine years with great success; but about that time an irreconcilable enmity took place between Handel and Senesino. From the conduct of Handel in this affair, he lost the good opinion of his friends. But in 1742 his popularity returned, and he retained his glory to the last. He died in 1759, and was buried in Westminster Abbey, where there is an elegant monument to his memory. A complete edition of his works was published by Dr. Arnold. His musical powers are best expressed by Arbutnot's reply to Pope, who seriously asked his opinion of him as a musician; "Conceive (said he) the highest you can of his abilities, and they are much beyond any thing you can conceive."

HANGING, the method of inflicting death on criminals by suspending them by the neck.

HANG-TCHEOU-FOU, the metropolis of the province of Tche-kiang in China. It is, according to the Chinese, the paradise of the earth. It is 12 miles in circumference, exclusive of its suburbs; and the number of its inhabitants amounts to more than a million. It is computed that there are 10,000 workmen within its walls employed in manufacturing silk. This city has a garrison of 3000 Chinese, under the command of the viceroy, and 3000 Tartars, commanded by a general of the same nation. It has under its jurisdiction seven cities of the second and third class.

HANIFAH, or **HANFA**, **ABA**, surnamed **Al Nooma**, the most celebrated Doctor of the orthodox Mussulmans. He was the son of Thabet, and was born at Coufah in the 80th year of the Hegira. He founded the sect of the Hanifites, which continues to be the most popular of the four principal sects among the Mussulmans. Like other teachers of new opinions, he suffered persecution during his life, being imprisoned at Bagdad till he died, by the Khalif Almansor, for refusing to subscribe to the doctrine of absolute predestination. But his opinions were afterwards brought into such credit, by Abou Joseph, a sovereign judge under the Khalif Hadi, that to be a Hanifite was reckoned synonymous with being a good Mussulman; and about 335 years after his death, which happened in the 150th year of the Hegira, Schaw Melick, in the 485th year of that era, and of the Christian, 1092, built a magnificent monument to his memory, and a college, which he appropriated solely to the professors of ABA Hanifah's doctrines. The most eminent of his successors were Achmed Ben Ali, Al Giaffas, and Al Razzi.

HANIFITES. See the last article.

HANKS, in naval affairs, are wooden rings fixed upon the stays to confine stay-sails at different distances. They are in place of gromets, being more convenient as well as of a later invention.

HANNIBAL, a famous Carthaginian general, and the son of Hamilcar, who made him swear eternal enmity to the Romans, at the age of eight years. On the death of Asdrubal, he obtained the command of the Carthaginian armies, and in three years subdued Spain. Having taken Saguntum, which was in alliance with the Romans, it occasioned the second Punic war, in which he shewed the most consummate generalship. He is said to have crossed the Alps by softening the rocks with fire and vinegar. On his arrival in Italy he defeated Cornelius Scipio, and obtained several victories over the most experienced Roman generals, particularly at Cannæ, where the Romans lost about 40,000 men, and had Hannibal pushed on for Rome it must have fallen. But by stopping at Capua, where his soldiers gave themselves up to luxury, the Romans recovered from their surprise; and when he appeared before the city, it excited so little concern, that the ground on which he was encamped was put up for sale, and sold at a high price. He soon retired and experienced a defeat near Zama. A

VOL. II.—NO. 101.

peace was then concluded; but Hannibal fearing the Romans, fled to Prusias king of Bithynia, and on hearing that the senate had sent to demand him, he poisoned himself, 182 B. C. (*Watkins.*)

HANNUYE, or **HANUYE**, a town of France in the department of the Dyle, and late province of Austrian Brabant; 20 miles S. E. of Louvain.

HANOVER, lately an electoral state of Germany, of which the king of Great Britain was elector. It was very considerable for the extent of its territories, which were, The duchy of Calenberg, in which are the cities of Hanover, Calenberg, Hamelen, Neustadt, Gottingen; &c. the duchy of Grubenhagen, the county of Diepholt, the county of Illoja, in the bishopric of Hildesheim; the bailiages of Coldingen, Luther, Badenburg, and Westershoven, with the right of protection of the city of Hildesheim; and the county of Danneberg, ceded by the Dukes of Wolfenbuttle to the dukes of Lunenburg, as an equivalent for their pretensions on the city of Brunswick. The whole of this country has lately been incorporated in the kingdom of Westphalia.

HANOVER, the capital of the above state is agreeably situated in a sandy plain on the Lyne, 25 miles W. of Brunswick, and 58 S. E. of Bremen. Lon. 9. 44. E. Lat. 52. 22. N.

HANOVER, a large island in the Pacific Ocean, opposite the N. W. extremity of New Ireland, 30 miles in length. The S. W. part of it is situated in Lon. 178. 27. E. Lat. 2. 49. S.

HANOVER, a county in Jamaica.

HANOVER, a town of the United States, in Grafton county, 115 miles N. W. by W. of Portsmouth.

HANOVER, **NEW**, a county of N. Carolina, in Wilmington district.

HANSE, an ancient name for a society or company of merchants; particularly that of certain cities in Germany, &c. hence called **Hanse-Towns**. The word is obsolete High Dutch or Teutonic; and signifies alliance, confederacy, or association. Some derive it from the German words, *am see*, that is, on the sea; as the first hanse-towns were all situated on the sea-coast: whence they are said to have been first called *am zee stenen*, *i. e.* cities on the sea; and afterwards, by abbreviation, *hansee*, and *hanse*.

The **HANSE-TOWNS**, or The **HANSEATIC SOCIETY** were several maritime cities of Germany, who entered into a league for the mutual protection of their commerce. Bremen and Amsterdam were the two first that formed it; whose trade received such advantage by their fitting out two men of war in each to convoy their ships, that more cities continually entered into the league: even kings and princes made treaties with them, and were often glad of their assistance and protection; by which means they grew so powerful both by sea and land, that they raised armies as well as navies, enjoyed countries in sovereignty, and made peace or war, though always in defence of their trade, as if they had been an united state or commonwealth.—At this time also many cities, though they had no great interest in trade, or intercourse with the ocean, came into their alliance for the preservation of their liberties; so that in 1200, we find no less than 72 cities in the list of the Hanse-Towns; particularly Bremen, Amsterdam, Antwerp, Rotterdam, Dort, Bruges, Ostend, Dunkirk, Middleburgh, Calais, Rouen, Rochelle, Bourdeaux, St. Malo, Bayonne, Bilbao, Lisbon, Seville, Cadiz, Carthage, Barcelona, Marseilles, Leghorn, Naples, Messina, London, Lubec, Rostock, Stralsund, Stetin, Wismar, Königsberg, Dantzic, Elbing, and Marienburg.

HAN-TCHONG, a city of China, in the province of Chen-si, on the Han, 625 miles S. W. of Peking.

HANWAY, **JONAS**, a gentleman eminent for his benevolent designs and useful writings, was born at Portsmouth in Hampshire, on the 12th of August 1712. Being bred a merchant he connected himself as a partner in Mr. Dingley's house, in St. Petersburg; where he arrived on the 10th of June 1743. The trade of the English over the Caspian Sea into Persia at this period had been entrusted to the care of Mr. Elton, who, had injudiciously engaged in the service of Nadir Shah, to build ships on the Caspian after the European manner. This had alarmed the merchants in the Russian trade, who resolved to send one of their body into Persia. On this occasion Mr. Hanway offered his service, which was accepted. He set out on the 10th Sept.; and, after experiencing various dangers in that kingdom during 12 months, returned to St. Petersburg, Jan. 1, 1745, without being able to establish the intended trade by the Caspian; partly through the

8 H

jealousy

jealousy of the Russian court on account of Elton's connections with the Persians, and partly by the Persian revolutions. Though Mr. Hanway's conduct during this expedition seems to have been directed by the strictest integrity, yet some difficulties arose in settling his demands on his employers. These were referred to the determination of impartial arbitrators, who at length decided in his favour. He now settled at St. Petersburg; where he remained five years, and interested himself greatly in the concerns of the merchants who had engaged in the Caspian trade. But having a desire to see his native country, he left St. Petersburg on the 9th of July 1750. On his arrival in London he employed himself some time as a merchant; but afterwards, more beneficially to the world, as an author. In 1753, he published "An Historical Account of the British Trade over the Caspian Sea; with a Journal of Travels from London through Russia into Persia; and back again through Russia, Germany, and Holland: To which are added, the Revolutions of Persia during the present Century, with the particular History of the great Usurper Nadir Kouli;" 4 vols. 4to. On settling in London, he devoted a considerable portion of his time to benevolent purposes, and was the principal institutor of the marine society, and the Magdalen Hospital. For these exertions he was made a commissioner of the navy; and when he resigned his seat at the board, his salary was continued. He died in 1786. He wrote several religious books of considerable merit; the best of which is entitled "Domestic Happiness promoted," 12mo. His publications amounted altogether to between 60 and 70. A list of them is given by his biographer Mr. Pugh.

HAN-YANG, a city of China, in the province of Hon-Quang, at the conflux of the Han and Yang-Tse, 587 miles W. of Pekin.

HAP, or HAPP, in law, signifies to catch or snatch a thing. Thus we meet with, to hap the possession of a deed-poll. Littleton, fol. 8; also, to hap the rent.

HAPPINESS, or FELICITY, absolutely taken, denotes the durable possession of good without any mixture of evil, or the enjoyment of pure pleasure unalloyed with pain; or a state in which all the wishes are satisfied. Relatively taken, happiness denotes the quantity of enjoyment of that which is esteemed good, whether pertaining to the body or the mind. In this sense a man's happiness will be in proportion to the good he enjoys, and it will be real or fancied according as that which he accounts good is so; for a man may esteem that a real good, which is in fact a real evil. Hence it is that many are happy only in the opinion of themselves or others, which indeed is the case with all those who are devoid of the fear and love of God. There can be no solid happiness but in an agreeable relation to, and enjoyment of God, who is perfectly happy in himself and the author of all happiness to his creatures, Gen. xxx. 13, Jer. xii. 1, Mal. iii. 15, Psalm lxxv. 4. Every thing that a man does, and every thing that he possesses, is calculated to make him happy in proportion to his performing or possessing it with the approbation of God: if God disapprove of it, it is his negative happiness or misery. And that every man may attain to happiness is manifest from divine revelation, for there God has declared Himself and his Will, and has shewn us the way to attain and retain his favour, and has promised to give the assurances of his love to those who attend to his revealed Will, and act accordingly; see Psalm lxxxix. 15, 16, James i. 25, Luke i. 77, 79.

HAPSAL, a sea-port of Russia, in Esthonia, 5 miles S. W. of Revel.

HAQUE, in old statutes, a little hand-gun, prohibited to be used for destruction of game, &c. by 33 Hen. VIII. cap. 6, and 2 and 3 Edw. VI. cap. 14.

HARAN, CHARRAN, or CHARRE, a city of Mesopotamia, celebrated for having been the place where Abraham retreated, after he left Ur (Gen. xi. 31, 32); where Terah, his father, died and was buried; whither Jacob retired, when he fled from Esau (id. xxvii. 45, xxviii. 10, &c.) and where Crassus the Roman general was defeated and killed by the Parthians. It was situated between the Euphrates and the Chebar, at a good distance from their junction.

HARBINGER, in the king's household, an officer who has four yeomen under him, who ride a day's journey before the court when it travels, to provide lodgings, &c.

HARBOROUGH, or MARKET HARBOROUGH, a town of Leicestershire, 83 miles N. N. W. of London.

HARBOUR, a place convenient for mooring shipping. The qualities requisite in a good harbour are, that the bottom be entirely free from rocks or shallows; that the opening be of sufficient extent to admit the entrance or departure of large ships without difficulty; that it should have good anchoring-ground, and be easy of access; that it should be well defended from the violence of the wind and sea; that it should have room and convenience to receive the shipping of different nations, and those which are laden with different merchandizes; that it should be furnished with a good light-house, and have variety of proper rings, posts, moorings, &c. in order to remove or secure vessels contained therein; and, finally, that it have plenty of wood, and other materials for firing, besides hemp, iron, mariners, &c.

HARDANGER, GULF OF, a bay in the North Sea, on the coast of Norway. Lon. 6. O. E. Lat. 59. 50. N.

HARDENING, the giving a greater degree of hardness to bodies than they had before. There are several ways of hardening iron and steel, as by hammering them, quenching them in cold water, &c. See CASE-HARDENING, and STEEL.

HARDERWICK, or HARDERWYCK, a town of Batavia, in the department of the Rhine, and late province of Dutch Guelderland, nineteen miles W. of Deventer.

HARDNESS, in physiology, that quality in bodies whereby their parts cohere firmly together, so as not to give way to any external impulse, nor yield inwards, without breaking. In this sense hardness coincides with what on other occasions we call firmness, in opposition to softness and fluidity. From that species of attraction called cohesion, it is easy to account for the different degrees of hardness in bodies: for the hardness will be in proportion to the cohesive force, and nearness of the constituent particles, together with the quantity of surface brought into contact. See ATTRACTION, COHESION, and PHYSICS. But nothing can conduce more to explain the nature of this doctrine, than the following passage of Sir Isaac Newton: "The parts of all homogeneous bodies, (says he,) which fully touch one another, stick together very strongly. And for explaining how this may be, some have invented hooked atoms, which is begging the question; and others tell us, that bodies are glued together by rest, that is, by an occult quality, or rather by nothing; and others, that they stick together by conspiring motions, that is, by relative rest among themselves. I had rather infer from their cohesion, that their particles attract one another by some force, which, in immediate contact, is exceeding strong; at small distances, performs many chemical operations, and reaches not far from the particles with any sensible effect. All bodies seem to be composed of hard particles: even the rays of light seem to be hard bodies; and therefore hardness may be reckoned the property of all uncompounded matter: for all bodies, so far as experience reaches, are either hard, or may be hardened. Now if compound bodies are so hard as we find some of them to be, and yet are very porous, and consist of parts which are only laid together, the simple particles which are void of pores, and were never yet divided, must be much harder. For such hard particles being heaped up together, can scarce ever touch one another in more than a few points, and therefore must be separable by a much less force than is requisite to break a solid particle where parts touch in all the space between them, without any pores or interstices to weaken their cohesion. And how such very hard particles, which are only laid together, and touch only in a few points, can stick together, and that so firmly as they do, without the assistance of something which causes them to be attracted, or pressed towards one another, is very difficult to conceive." Since heat diminishes the cohesion of bodies, it renders them softer, and when so much heat is applied as to destroy the cohesion, the body in consequence of the heat becomes fluid. Mr. Quist and others have constructed tables of the hardness of different substances. The method pursued in constructing these tables was, by observing the order in which they were able to cut or make any impression upon one another. The following table, extracted from M. Magellan's edition of Cronstedt's Mineralogy, was taken from Dr. Quist, Sir T. Bergman, and Mr. Kirwan. The first column shews the hardness, and the second the specific gravity.

HARE, in zoology. See **LEPUS**.

HARESBURY, an ancient borough of Wiltshire, on the Willy, near Warminster, ninety-four miles from London, in old records called Heightsbury, or Heytsbury; and now written Hatchbury.

HARFLEUR, an ancient town of France, in the department of Lower Seine, and late province of Normandy, thirty-six miles N. W. of Rouen.

HARIDI, a serpent, worshipped at Achmin in Upper Egypt.

HARJEDALEN, a province of Sweden, in Nordland, about 100 miles long, and from 40 to 50 broad; abounding in pastures, cattle, woods, mines, lakes, rivers, and fish.

HARIOT, or **HERIOT**, in law, a due belonging to a lord at the death of his tenant, consisting of the best beast, either horse, or cow, or ox, which he had at the time of his death; and in some manors the best goods, piece of plate, &c. are called harlots.

HARISCHON, **AARON**, a learned rabbi, and Karaite, in the fifteenth century; who wrote a Hebrew grammar, printed at Constantinople, in 1581: probably the same with Aaron, the Karaite, a Jewish physician at Constantinople, who, about 1294, wrote a Commentary on the Pentateuch, printed at Jena, in folio, in 1710, and of which there is an original MS. copy in the National Library at Paris.

HARLEBACK, a town of France, in the department of Lys, and late province of Austrian Flanders, four miles N. E. of Courtray.

HARLECH, or **HARLEICH**, a town of North Wales, in Merionethshire, twenty-four miles S. of Caernarvon.

HARLEM, or **HAERLEM**, a large and populous city of Batavia, in the department of Amstel, and late province of Holland, ten miles W. of Amsterdam.

HARLEQUIN, in the Italian comedy, a buffoon, dressed in party-coloured cloaths; answering much the same purpose as a merry andrew in our drolls, on mountebanks, stages, &c.

HARLESTON, a town of Norfolk, seated on the Waveney, sixteen miles S. of Norwich.

HARLING, or **HERLING**, a town in Norfolk, eighty-eight miles N. E. of London.

HARLINGEN, a sea-port town of Batavia, in the department of the Eems, and late province of West Friesland, fourteen miles W. of Lewarden. Lon. 5. 25. E. Lat. 53. 11. N.

HARLOW, a town in Essex, twenty-three miles N. E. of London.

HARMA, [Gr. *Ἀρμα*, a chariot,] an ancient town of Bœotia, said to have been built on the spot, where Amphiarus was swallowed up with his chariot: whence the name.

HARMATTAN, a remarkable periodical wind which blows from the interior parts of Africa towards the Atlantic ocean. Of this wind we have an account in the Philosophical Transactions, vol. 71, furnished by Mr. Norris. On that part of the coast of Africa which lies between Cape Verd in Lat. 15° N. and Cape Lopez in Lat. 1° S. this wind prevails during December, January, and February. The coast between these two capes runs in an oblique direction nearly from W. S. W. to E. S. E. forming a range of upwards of 2100 miles. At the Isles de Los, which are a little to the N. of Sierra Leone, and to the S. of Cape Verd, it blows from the E. S. E. on the Gold Coast from the N. E. and at Cape Lopez, and the river Gabon, from the N. N. E. This wind is by the French and Portuguese, who frequent the Gold Coast, called simply the N. E. wind, the quarter from which it blows. The English adopt the word *Harmattan*, used by the Fantees, a nation on the Gold Coast. It comes on indiscriminately at any hour of the day, at any time of the tide, or at any period of the moon, and continues sometimes only a day or two, sometimes five or six days, and it has been known to last fifteen or sixteen. There are generally three or four returns of it every season. It blows with a moderate force, not quite so strong as the sea-breeze (which every day during the fair season from the W. W. S. W. and S. W.): but somewhat stronger than the land-wind at night from the N. and N. N. W. A fog is one of the peculiarities which always accompanies the harmattan. The gloom occasioned by this fog is so great, as sometimes to make even near objects obscure. Extreme dryness makes another extraordinary property of this wind; no dew falls during its continuance; vegetables are withered, and the grass becomes dry like hay. The natives take this opportunity to clear the land, by setting fire to the trees and plants while in that dry and exhausted state. The dryness is so extreme, that the covers of books, even closely shut up in a trunk, are bent as if exposed to the fire. Household furniture is much damaged; the pannels of wainscots split, and fineered work flies to pieces. Though this wind is fatal to vegetable life, and occasions troublesome effects to the human species, it is nevertheless highly conducive to health; it stops the progress of epidemics, and relieves the patients labouring under fluxes and intermittent fevers. Infection is not easy at that time to be communicated, even by inoculation. It is also remarkable for the cure of ulcers and cutaneous diseases.

HARMONICA. This word, when originally appropriated by Dr. Franklin to that peculiar form or mode of musical glasses, which he himself, after a number of happy experiments, had constituted, was written *Armonica*. It is derived from the Greek word *ἁρμονία*. The radical word is *ἁρμω*, to suit or fit one thing to another. By the word *ἁρμονία* the Greeks expressed aptitudes of various kinds; and from the use which they made of that expression, we have reason to conclude, that it was intended to import the highest degree of refinement and delicacy in those relations which it was meant to signify. Relations or aptitudes of sound, in particular, were understood by it; and in this view, Dr. Franklin could not have selected a name more expressive of its nature and genius, for the instrument we are now to describe; as, perhaps, no musical tone can possibly be finer, nor consequently susceptible of juster concords, than those which it produces. The doctor, in his letter to F. Beccaria, has given a minute and elegant account of the Harmonica. "Perhaps (says he) it may be agreeable to you, as you live in a musical country, to have an account of the new instrument lately added here to the great number that charming science was possessed of before. As it is an instrument that seems peculiarly adapted to Italian music, especially that of the soft and plaintive kind, I will endeavour to give you such a description of it, and of the manner of constructing it, that you or any of your friends may be enabled to imitate it, if you incline so to do, without being at the expence and trouble of the many experiments I have made in endeavouring to bring it to its present perfection. You have doubtless heard the sweet tone that is drawn from a drinking-glass, by pressing a wet finger round its brim. One Mr. Puckeridge, a gentleman from Ireland, was the first who thought of playing tunes formed of these tones. He collected a number of glasses of different sizes; fixed them near each other on a table; and tuned them, by putting into them water, more or less, as each note required. The tones were brought out by pressing his fingers round their brims. He was unfortunately burnt here,

here, with his instrument, in a fire which consumed the house he lived in. Mr. E. Delaval, a most ingenious member of our Royal Society, made one in imitation of it, with a better choice and form of glasses, which was the first I saw or heard. Being charmed with the sweetness of its tones, and the music he produced from it, I wished to see the glasses disposed in a more convenient form, and brought together in a narrower compass, so as to admit of a greater number of tones, and all within reach of hand to a person sitting before the instrument; which I accomplished after various intermediate trials, and less commodious forms, both of glasses and construction in the following manner. The glasses are blown as near as possible in the form of hemispheres, having each an open neck or socket in the middle. The thickness of the glass near the brim is about the tenth of an inch, or hardly quite so much, but thicker as it comes nearer the neck; which in the largest glasses is about an inch deep, and an inch and a half wide within; these dimensions, lessening as the glasses themselves diminish in size, except that the neck of the smallest ought not to be shorter than half an inch. The largest glass is nine inches diameter, and the smallest three inches. Between these are twenty-three different sizes, differing from each other a quarter of an inch in diameter. To make a single instrument there should be at least six glasses blown of each size; and out of this number one may probably pick thirty-seven glasses (which are different for three octaves with all the semitones) that will be each either the note one wants, or a little sharper than that note, and all sitting so well into each other as to taper pretty regularly from the largest to the smallest. It is true there are not thirty-seven sizes; but it often happens that two of the same size differ a note or half a note in tone, by reason of a difference in thickness, and these may be placed in the other without sensibly hurting the regularity of the taper form. The glasses being chosen, and every one marked with a diamond the note you intend it for, they are to be tuned by diminishing the thickness of those that are too sharp. This is done by grinding them round from the neck towards the brim, the breadth of one or two inches as may be required; often trying the glass by a well-tuned harpsichord, comparing the note drawn from your glass by the finger with the note you want, as sounded by that string of the harpsichord. When you come near the matter, be careful to wipe the glass clean and dry before each trial, because the tone is something flatter when the glass is wet than it will be when dry; and grinding a very little between each trial, you will thereby tune to great exactness. The more care is necessary in this, because if you go below your required tone there is no sharpening it again but by grinding somewhat off the brim, which will afterwards require polishing; and thus increase the trouble. The glasses being thus tuned, you are to be provided with a case for them, and a spindle on which they are to be fixed. My case is about three feet long, eleven inches every way wide within at the biggest end, and five inches at the smallest end; for it tapers all the way, to adapt it better to the conical figure of the set of glasses. This case opens in the middle of its height, and the upper part turns up by hinges fixed behind. The spindle is of hard iron, lies horizontally from end to end of the box within, exactly in the middle, and is made to turn on brass-gudgeons at each end. It is round, an inch in diameter at the thickest end, and tapering to a quarter of an inch at the smallest. A square shank comes from its thickest end through the box, on which shank a wheel is fixed by a screw. This wheel serves as a fly to make the motion equable, when the spindle, with the glasses, is turned by the foot like a spinning-wheel. My wheel is of mahogany, eighteen inches diameter, and pretty thick, so as to conceal near its circumference about 25lb. of lead. An ivory pin is fixed in the face of this wheel, about four inches from the axis. Over the neck of this pin is put the loop of the string, that comes up from the moveable step to give it motion. The case stands on a neat frame with four legs. To fix the glasses on the spindle, a cork is first to be fitted in each neck pretty tight, and projecting a little without the neck, that the neck of one may not touch the inside of another when put together, for that would make a jarring. These corks are to be perforated with holes of different diameters, so as to suit that part of the spindle on which they are to be fixed. When a glass is put on, by holding it stiffly between both hands, while another turns the spindle, it may be gradually brought to its place. But care must be taken that the hole be not too small, lest in forcing it up the neck should split; nor too large, lest the glass, not being firmly fixed, should turn or

move on the spindle, so as to touch or jar against its neighbouring glass. The glasses thus are placed one in another; the largest on the biggest end of the spindle, which is to the left hand: the neck of this glass is towards the wheel; and the next goes into it in the same position, only about an inch of its brim appearing beyond the brim of the first; thus proceeding, every glass when fixed shews about an inch of its brim (or three quarters of an inch, or half an inch, as they grow smaller) beyond the brim of the glass that contains it; and it is from these exposed parts of each glass that the tone is drawn, by laying a finger on one of them as the spindle and glasses turn round. My largest glass is G a little below the reach of a common voice, and my highest G, including three complete octaves. To distinguish the glasses more readily to the eye, I have painted the apparent parts of the glasses within-side, every semitone white, and the other notes of the octave with the seven prismatic colours; viz. C, red; D, orange; E, yellow; F, green; G, blue; A, indigo; B, purple; and C, red again; so that the glasses of the same colour (the white excepted) are always octaves to each other. This instrument is played upon by sitting before the middle of the set of glasses, as before the keys of a harpsichord, turning them with the foot, and wetting them now and then with a sponge and clean water. The fingers should be first a little soaked in water, and quite free from all greasiness; a little fine chalk is sometimes useful, to make them catch the glass and bring out the tone more readily. Both hands are used, by which means different parts are played together. Observe, that the tones are best drawn out when the glasses turn from the ends of the fingers, and not when they turn to them. The advantages of this instrument are, that its tones are incomparably sweet beyond those of any other; that they may be swelled and softened at pleasure by stronger or weaker pressures of the finger, and continued to any length; and that the instrument, being once well tuned, never again wants tuning." A farther account of this instrument is inserted in the Annual Register, vol. iv. p. 149. The author proposes to use cork instead of the finger, but this substitute does not seem capable of producing the same mellowness and equality of tone with the finger. Alum-water is also thought preferable to chalk. From what has already been said, it will easily be perceived, that this instrument requires to be tuned with the nicest degree of delicacy which the laws of temperament will possibly admit. See MUSIC, and TEMPERAMENT. The same rules, however, which are observed in tuning a harpsichord, will be equally effectual in tuning the Harmonica; with this only difference, that greater delicacy in adjusting the chords should, if practicable, be attempted. On Plate LXXXV. fig. 3, is represented an instrument of this kind, made by Mr. Dobb of St. Paul's church-yard, London.

HARMONICAL ARITHMETIC, that part of arithmetic which considers musical intervals, expressed by numbers, in order to our finding their mutual relations, compositions, and resolutions.

HARMONICAL COMPOSITION, in a general sense, includes both harmony and melody, *i. e.* of music or songs, both in a single part and in several parts.

HARMONICAL INTERVAL, in music, denotes the difference of two sounds, which is agreeable to the ear, whether in consonance or succession; and are, therefore, the same with concord. See CONCORD and INTERVAL.

HARMONICAL PROPORTION. See PROPORTION.

HARMONICAL SERIES, a series of many numbers in continual harmonical proportion. Thus if there are four or more numbers, of which every three immediate terms are harmonical, the whole will make a harmonical series: such as 30 : 20 : 15 : 12 : 10. Or, if every four terms immediately next each other are harmonical, it is also a continued harmonical series, but of another species, as 3, 4, 6, 9, 18, 36, &c.

HARMONICAL SOUNDS, an appellation given, by Mr. Sauveur, to such sounds as always make a determinate number of vibrations, in the time that one of the fundamentals, to which they are referred, makes one vibration.

HARMONICS, the concomitant or accessory sounds, which, upon the principles resulting from the experiments made on sonorous bodies, attend any given sound, whatever, and render it appreciable. Thus all the aliquot parts of a musical string produce harmonics, or harmonical sounds.

HARMONY, [*ἁρμονία*.] In the ancient treatises on music that

are extant, harmony appears to be that department whose object is the agreeable succession of sounds, merely considered as high or low; in opposition to the two others called *rhythmica* and *metrica*, which have their principle in time and measure. This leaves our ideas concerning that aptitude of sound vague and undetermined; nor can we fix them without studying for that purpose all the rules of the art: and even after we have done so, it will be very difficult to distinguish harmony from melody, unless we add to the last the ideas of rhythmus and measure: without which, in reality, no melody can have a distinguishing character: whereas harmony is characterised by its own nature, independent of all other quantities except the chords or intervals which compose it. It appears by a passage of Nicomachus, and by others, that they likewise gave the name of harmony to the chord of an octave, and to concerts of voices and instruments, which performed in the distance of an octave one from the other, and which is more commonly called antiphone.

HARMONY, according to the moderns, is a succession of chords agreeable to the laws of modulation. For a long time this harmony had no other principle but such rules as were almost arbitrary, or solely founded on the approbation of a practised ear, which decided concerning the agreeable or disagreeable succession of chords, and whose determinations were at last reduced to calculation. But F. Mersenne and M. Saveur having found that every sound, however simple in appearance, was always accompanied with other sounds less sensible, which constitute with itself a perfect chord-major; with this experiment M. Rameau set out, and upon it formed the basis of his harmonic system, which he has extended to many volumes, and which at last M. D'Alembert has taken the trouble of explaining to the public. Signior Tartini, taking his route from an experiment which is newer and more delicate, though not less certain, has reached conclusions like those of Rameau, by pursuing a path whose direction seems quite opposite. According to Rameau the treble is generated by the bass; Signior Tartini makes the bass result from the treble. One deduces harmony from melody, and the other supposes quite the contrary. To determine from which of the two schools the best performances are likely to proceed, no more is necessary than to investigate the end of the composer, and discover whether the air is made for the accompaniments, or the accompaniments for the air. See **CHORD**, **DISCORD**, **ENHARMONIC**, **FUNDAMENTAL BASS**, **MODULATION**, **MUSIC**, &c.

HARMONY, DIRECT, is that in which the bass is fundamental, and in which the upper parts preserve among themselves, and with that fundamental bass, the natural and original order which ought to subsist in each of the chords that compose this harmony.

HARMONY, INVERTED, is that in which the fundamental or generating sound is placed in some of the upper parts, and when some other sound of the chord is transferred to the bass beneath the others.

HARMONY is also sometimes used to denote an agreement, suitableness, union, conformity, &c. thus, in music, we sometimes apply it to a single voice, when sonorous, clear, and soft; to a single instrument, when it yields a very agreeable sound: in matters of literature we use it for a certain agreement between the several parts of the discourse: in architecture harmony denotes an agreeable relation between the parts of a building: in painting they speak of an harmony both in the ordonnance and composition, and in the colours of a picture: in the ordonnance it signifies the union or connection between the figures, with respect to the subject of the piece; in the colours it denotes the union or agreeable mixture of different colours. See **SYMMETRY**, **COLOURING**, &c.

HARMONY OF THE SPHERES, or **CELESTIAL HARMONY**, a sort of music much talked of by many of the ancient philosophers and fathers, supposed to be produced by the sweetly tuned motions of the stars and planets. This harmony they attributed to the various proportionate impressions of the heavenly globes upon one another, acting at proper intervals. It is impossible, according to them, that such prodigious large bodies, moving with so much rapidity, should be silent; on the contrary, the atmosphere continually impelled by them, must yield a set of sounds proportionate to the impression it receives; consequently as they do not all run the same circuit, nor with one and the same velocity, the different tones arising from the diversity of motions, directed by the hand of the Almighty, must form an admirable sympathy, or concert. They therefore supposed that the moon, as being the

lowest of the planets, corresponded to *mi*; Mercury, to *fa*; Venus, to *sol*; the Sun, to *la*; Mars, to *si*; Jupiter, to *ut*; Saturn, to *re*; and the orb of the fixed stars, as being the highest of all, to *mi*, or the octave.

HARMOSTA, or **HARMOSTES**, [*Ἀρμόστης*, from *ἀρμόω*, to adapt,] in antiquity, a magistrate among the Spartans, whereof there were several, whose business was to look to the buildings of citadels, and repairing the forts and fortifications.

HARMOSYNIANS, [*ἁρμόσυνοι*,] in antiquity, magistrates among the Spartans, who, after the death of Lycurgus, were appointed to enforce the observance of that law, which required married women to wear veils in the streets; whereby they were distinguished from single females, who were allowed to go abroad with their faces uncovered.

HARNESS, comprehends the whole equipage and accoutrements of a cavalier heavily armed: as casque, cuirass, &c. Some derive the word from the Greek *ἀρνίον*, a lamb's skin, because they anciently covered themselves therewith.

HARO, a town of Spain, in Old Castile, on the Ebro, 32 miles N.E. of Burgos.

HARO, **HAROL**, or **HAROU**, of **CLAMOUR DE HARO**, in the Norman customs, was a cry or formula of invoking the assistance of justice against the violence of some offender, who, upon hearing the word *haro*, was obliged to desist, on pain of being severely punished for his outrage, and to go with the party before the judge. The word is commonly derived from *ha* and *roul*, as being supposed an invocation of the sovereign power, to assist the weak against the strong; from *Raoul*, first duke of Normandy.

HARP, a musical instrument of the string-kind, of a triangular figure, held upright between the legs of the person who plays upon it. Papias and Du Cange suppose its name derived from the *Arpi*, a people of Italy, who invented it, and from whom, they say, it was borrowed by other nations. Menage, &c. derive the word from the Latin *harpa*, and that from the German *herp* or *harp*. Others trace it from the Latin, *carpo*, because thrummed with the fingers. Dr. Hickes derives it from *harpa* or *hearpa*, which signify the same thing in the Cimbric and Anglo-Saxon. The harp was the favourite musical instrument of the Britons and other northern nations in the middle ages; as is evident from their laws, and various passages in their history. By the laws of Wales a harp was one of the three things that were necessary to constitute a gentleman or a freeman; and none could pretend to that character who had not one of these favourite instruments, or could not play upon it. That the harp is among the most ancient of musical instruments, the frequent mention of it in scripture, and the splendid account transmitted to us of the Theban harp, both as to the beauty of its decorations and extent of scale, are sufficient evidences. The Irish and Welsh practised the harp long before the gammut of Guido was invented, and it is indeed their national instrument. The harp was in no less estimation and universal use among the Saxons and Danes. There is some diversity in the structure of harps. That called the triple harp has three rows of strings and chords, which in all make seventy eight, or four octaves; the second row makes the half-turn, and the third is unison with the first.

HARP, EOLIAN. See **ACOUSTICS**.

HARP, THE BELL, a musical instrument of the string-kind, thus called from the players on it swinging it about as a bell on its basis. It is about three feet long; its strings which are of no determinate number, are of brass or steel wire, fixed at one end, and stretched across the sound board by screws fixed at the other. It takes in four octaves, according to the number of the strings, which are struck only with the thumbs, the right hand playing the treble, and the left hand the base: and in order to draw the sound the clearer, the thumbs are armed with a little wire-pin. This may perhaps be the *lyra*, or *cythara*, of the ancients; but we find no mention made of it under the name it now bears, which must be allowed to be modern.

HARPAGINES, [*ἁρπάγες*,] in antiquity, were hooks of iron, hainging on the top of a pole, which, being secured with chains to the masts of ships, and then let down with great velocity into the enemy's vessels, caught them up into the air.

HARPASA, a town of Caria, on the Harpasus, famous for an immense rocking-stone, which was moveable by the finger, but could not be displaced by any force.

HARPE

HARPE, in mythology, a crooked sword wherewith Mercury cut off Argus's head, and Perseus that of Medusa.

HARPIES. See **HARPY**, and **HARPYIÆ**.

HARPING-IRON, [from *harpago*, Lat.] a bearded dart with a line fastened to the handle, with which whales are struck and caught.

HARPING-IRON. See **HARPOON**.

HARPINGS, the fore-parts of the wales which encompass the bow of a ship, and are fastened to the stem, being thicker than the after-part of the wales, in order to reinforce the ship in this place, where she sustains the greatest shock of resistance in plunging into the sea, or dividing it, under a great pressure of sail.

HARPOCRATES, in mythology, the son of Isis and Osiris; an Egyptian deity, represented with his fingers applied to his mouth, denoting that he is the god of silence.

HARPONELLY, a district of Hindostan, in the Mysore country.

HARPONELLY, the capital of the above district, 65 miles N.N.E. of Bedamore.

HARPOON, [*harpon*, Fr.] a harping-iron. This instrument is a spear or javelin used to strike the whales in the Greenland fishery. It is furnished with a long staff, having at one end a broad and flat triangular head, sharpened at both edges, so as to penetrate the whale with facility: to the head of this weapon is fastened a long cord, called the whale-line, which lies carefully coiled in the boat, in such a manner as to run out without being interrupted or entangled. See **WHALE-FISHERY**.

HARPOON, GUN, a kind of fire-arm for discharging harpoons at whales, and thereby killing them more expeditiously than formerly, when the harpoons were thrown by the hand. Though this method was projected many years ago, it has but lately come into use; and premiums have been annually offered by the society for encouraging arts, &c. to the persons who first struck a fish in this manner. In the Transactions of that society for 1786, we have an account of the first fish struck in this manner in 1784. The gun was of the blunderbuss-construction, loaded with four common tobacco-pipes full of glazed powder; the fish was shot at the distance of ten fathoms, the harpoon going into her back up to the ring; and she was killed in about an hour. In 1785, three whales were killed in this manner; four in 1786, and three in 1787. Since that time the gun-harpoon has come more into use, and will probably soon supersede the other method entirely. In the Philosophical Transactions for 1789, we have accounts of a number of whales killed in this manner. The instrument appears to be extremely useful in calm weather, as the whale, though a timorous creature, will frequently allow a boat to approach it within twenty, fifteen, or even ten, fathoms, all of which distances are within reach of the gun-harpoon, though not within the reach of that thrown by the hand. The greatest inconvenience was in case of rain or snow, by which the lock was apt to get wet. To remedy this, a case of leather was made to fit round the gun, and over the lock, lined with tin, and big enough to fire the gun when it was on. The fish struck with an harpoon discharged in this manner are soon killed, by reason of its penetrating their bodies to the depth of five or six feet, which no man's strength would be able to accomplish. In the volume just quoted, we have an account of one which was shot through the tail. The harpoon broke in the slit, but five fathoms of line went through the tail. The fish was killed in eight hours, which is perhaps the only instance of a fish struck in that part being caught. In another the harpoon carried six feet of line into its body, and the creature died in ten minutes. Others were killed in fifteen minutes or half an hour, and one had a rib broken by the violence of the stroke. See Plate LXXXV. fig. 1.

HARPSICORD, a musical instrument, strung with wires, and played by striking keys. This is the most harmonious of all the musical instruments of the string-kind. It is played on after the manner of the organ, and is furnished with a set, and sometimes with two sets, of keys; the touching or striking of these keys moves a kind of little jacks, which also move a double row of strings of brass or iron, stretched over four bridges on the table of the instrument.

HARPYIÆ, [*ἁρπυιᾶ*] the **HARPIES**, in mythology, were a rapacious impure sort of monsters, with wings and bears like bears, bodies like vultures, faces like women, and feet and hands

hooked like the talons of birds of prey. The ancients believed the harpies to be genii or demons.

HARQUEBUSS, a kind of a gun, of the length of a musket, usually cocked with a wheel. It carries a ball weighing one ounce and seven-eighths. There was also a larger sort, called the great harquebuss, used for the defence of strong places, which carried a ball of about three ounces and a half. They are now little used, except in some old castles and garrisons.

HARRIOT, THOMAS, an eminent algebraist, born at Oxford in 1560, where he took the degree of B. A. in 1579. Being distinguished for his mathematical learning, he was recommended to Sir Walter Raleigh, who, in 1585, sent him with the colony, under Sir Richard Greenville to Virginia. After having remained there about a year, he published a topographical description of it. About 1588, he was introduced by his patron Sir Walter Raleigh to Henry, Earl of Northumberland, who allowed him a pension of 120*l.* per annum. He spent many years in Sion College; where he died in July 1621, of a cancer in his lip, and was buried in the church of St. Christopher, where a handsome monument was erected to his memory. He was one of the first mathematicians of the age in which he lived, and will always be remembered as the inventor of the present improved method of algebraical calculation; which was adopted by Des Cartes, and for a considerable time imposed upon the French nation as his own invention; but the theft was at last detected by Dr. Wallis, in his History of Algebra, where our author's invention is accurately specified. His works are, 1. A Brief and true Report of the New-found land of Virginia; of the Commodities there found, and to be raised, &c. 2. *Artis Analyticæ Praxis ad Equationes Algebraicas nova expedita, et generali Methodo resolvendas, e Posthumis Thomæ Harrioti, &c.* 3. *Ephemeris Chyrometrica*; MS. in the library of Sion College. He left several other MSS. which were inspected by Dr. Zach, astronomer to the duke of Saxe-Gotha, in 1784, at Petworth in Sussex, the seat of the Earl of Eversmont, a descendant of Henry, Earl of Northumberland. Dr. Zach published an account of them in the Astronomical Ephemeris for 1788: from which it appears, that Harriot had made great discoveries in astronomy, particularly that he had observed the spots in the sun so early as Dec. 8, 1610; which was eighteen months earlier than Galileo's first published observations respecting them; and that he had also discovered the satellites of Jupiter, and made drawings of their positions, and calculations of their revolutions, in Jan. 1610, the same month when Galileo discovered them. Dr. Zach adds, that Harriot's observations of the comet of 1607 are still of use.

HARRIS, JAMES, Esq. an English gentleman of very uncommon parts and learning, the son of James Harris, Esq. by a sister of Lord Shaftesbury, author of *The Characteristics*. He was born at Salisbury, in 1709; and educated there. In 1726, he was removed to Wadham College in Oxford. He was member for Christ-church, Hants, in several successive parliaments. In 1763, he was appointed a lord-commissioner of the admiralty, and soon after removed to the board of treasury. In 1774 he was made secretary and comptroller to the queen, which post he held until his death. He died Dec. 21, 1780, in his seventy-second year, after a long illness. He was author of some valuable works: 1. *Three Treatises*: concerning Art; Music, Painting, and Poetry; and *Happiness*, 1745, 8vo. 2. *Hermes*; or, *A Philosophical Enquiry concerning Universal Grammar*. 3. *Philosophical Arrangements*. 4. *Philological Enquiries*; 1782, 2 vols. 8vo. published since his death.

HARRIS, a peninsula of the Hebrides, forming with Lewis one of the Western Islands of Scotland. Harris is twenty miles long, and ten broad.

HARRISBURGH, or **LOUISBURG**, a post-town of Pennsylvania, and the capital of Dauphine county, seated on the Susquehanna, eighty miles W. of Pennsylvania.

HARRISON, JOHN, the celebrated inventor of the famous time-keeper for ascertaining the longitude at sea, and also of the compound, or, as it is commonly called, the gridiron-pendulum; was born at Foulby, near Pontefract in Yorkshire, in 1693. The vigour of his natural abilities, if not strengthened by want of education, which confined his attention to few objects, at least amply compensated for it; as appeared from the astonishing progress he made in that branch of mechanics to which he devoted himself. His father was a carpenter, in which he assisted, and occasionally surveyed

surveyed land, and repaired clocks and watches. He was, from his childhood, attached to any machinery moving by wheels, as appeared while he lay sick of the small-pox about the sixth year of his age, when he had a watch placed open upon his pillow, to amuse himself by contemplating the movement. In 1700, he removed with his father to Barrow in Lincolnshire; where he eagerly improved every incident from which he might collect information; frequently employing great part of his nights in writing or drawing; and he always acknowledged his obligations to a clergyman who lent him a MS. copy of professor Saunderson's Lectures; which he carefully transcribed, with all the diagrams. In 1726, he had constructed two clocks, mostly of wood, in which he applied the escapement and compound pendulum of his own invention: these surpassed every thing then made, scarcely erring a second in a month. In 1728, he came up to London with the drawings of a machine for determining the longitude at sea, in expectation of being enabled to execute one by the Board of Longitude. Upon application to Dr. Halley, he referred him to Mr. George Graham; who advised him to make his machine before he applied to the Board. He returned home to perform this task; and in 1735 came to London with his first machine; with which he was sent to Lisbon the next year for a trial of its properties. In this short voyage he corrected the dead reckoning about a degree and a half; which success procured him both public and private encouragement. About 1739, he completed his second machine, of a construction much more simple than the former, and which answered much better: this, though not sent to sea, recommended him still more to patronage. His third machine in 1749, was still less complicated than the second, and superior in accuracy, erring only three or four seconds in a week. This he conceived to be the ne plus ultra of his attempts: but in an endeavour to improve pocket-watches, the principles he applied surpassed his expectations so much, as to encourage him to make his fourth time-keeper, which is in the form of a pocket-watch, about six inches diameter. With this time-keeper his son made two voyages, the one to Jamaica, and the other to Barbadoes; in both which experiments it corrected the longitude within the nearest limits required by the act of the 12th of Queen Anne; and the inventor, therefore, at different times, though not without great trouble, received the proposed reward of 20,000*l*. These four machines were given up to the Board of Longitude. The three former were now of no use, as all their advantages were comprehended in the last; they were worthy, however, of being carefully preserved as mechanical curiosities, in which might be traced the gradations of ingenuity executed with the most delicate workmanship. They are kept in the Royal Observatory at Greenwich. The fourth machine, emphatically called the time-keeper, has been copied by the ingenious Mr. Kendal; and that duplicate, during a three years circumnavigation of the globe in the southern hemisphere by Captain Cook, answered as well as the original. The latter part of Mr. Harrison's life was employed in making a fifth improved time-keeper on the same principles with the preceding one; which, at the end of a ten weeks trial, in 1772, at the king's Private Observatory at Richmond, erred only four seconds and a half. Within a few years of his death, he had frequent fits of the gout, a disorder that never attacked him before his seventy-seventh year: he died at his house in Red-Lion Square, in 1776, aged eighty-three. His reclusive manner of life, in the unremitting pursuit of his favourite object, was not calculated to qualify him as a man of the world; and the many discouragements he encountered, in soliciting the legal reward of his labours, still less disposed him to accommodate himself to the humours of mankind. In conversing on his profession, he was clear, distinct, and modest; but found a difficulty in explaining his meaning by writing; in which he adhered to a peculiar and uncouth phraseology. This was evident in his "Description concerning such Mechanism as will afford a nice or true Mensuration of Time," &c. 8vo. 1775; in which he obstinately refused to accept of any assistance whatever. This work contains also an account of his new musical scale; or mechanical division of the octave, according to the proportion which the radius and diameter of a circle have respectively to the circumference. He had in his youth been the leader of a distinguished band of church-singers; had a very delicate ear for music; and his experiments on sound, with a most curious monochord of his own improvement, are reported to have been no less accurate than those he was engaged in for the mensuration of time.

HARRISON, in geography, a county of Virginia, bounded on the N. E. by Monongalia, S. by Greenbrier, S. W. by Kanhawa, and N. by Ohio county. It is 120 miles long, and eighty broad; Clarksburg is the capital.

HARRISTOWN, a town of Ireland, in Kildare, Leinster, eighteen miles S. W. of Dublin.

HARRODSBURG, or **HARRODSTOWN**, a town of Kentucky, in Mercer county, twenty-five miles S. W. of Lexington.

HARROGATE, or **HARROWGATE**, a village in the W. Riding of Yorkshire, in the parish of Knaresborough, remarkable for its chalybeate and sulphureous springs. Formerly, the chalybeate-water only was used internally, and the sulphureous spring was exclusively employed as an external remedy. At present, however, considerable quantities of the latter are drunk for various complaints. The sulphureous water is obtained from four springs, that rise apparently from a large bog situated at a small distance from the wells; and which is composed of decayed vegetable matter, forming a black, half-fluid, foetid mass, four or five feet thick, and supported by a bed of clay and gravel. When first drawn, the Harrogate water is transparent, and emits a few air-bubbles. It possesses a strongly foetid sulphureous smell, similar to that of bilge-water; and is of a bitter, nauseous, and strongly saline, taste. After being exposed for several hours to the open air, it becomes turbid, assumes a greenish colour, loses its sulphureous smell, and deposits sulphur at the bottom and sides of the vessel.

HARROW, [*charroue*, Fr. *harcke*, Germ. a rake,] in agriculture, a frame of timbers crossing each other, and set with teeth, drawn over sowed ground to break the clods, and throw the earth over the seed. See **HUSBANDRY**.

HARROWGATE. See **HARROGATE**.

HART, a stag, or male deer, in the sixth year. See **CERVUS**.

HARTS, **HORNS OF**, the horns of the male deer. The scrapings or raspings of these, are medicinal, and used in decoctions, ptisans, &c. The horns of harts yield by distillation a very penetrating volatile spirit called Volatile Alkali, or Ammonia; which is also procured in equal perfection from the horns, bones, &c. of other animals. See **ALKALI**, and **AMMONIA**.

HARTFORD, a populous and hilly country of Connecticut, bounded on the E. by Tolland.

HARTFORD, a flourishing city in the above county. It lies 50 miles W. of Boston.

HARTLEPOOL, a sea-port town in Durham, 10 miles N. of Stockton.

HARTLEY, **DAVID**, M. A. an eminent physician, born in 1704, at Iltingworth, where his father was curate. He received his academical education at Jesus college, Cambridge, of which he was a fellow. He first practised physic at Newmark upon Trent; afterwards at London; and lastly went to Bath, where he died in 1757, aged 53, leaving two sons and a daughter. He published "A View of the Evidence for and against Mrs. Stephens's Medicines as a Solvent for the Stone, containing 155 Cases with some Experiments and Observations;" London, 1739. He is also said to have written against Dr. Warren, of St. Edmundsbury, in defence of inoculation; and some letters of his are to be met with in the Philosophical Transactions. His chief literary production is "Observations on Man, his Frame, his Duty, and his Expectations, in two parts;" London, 1749, 8vo.

HARTLEY, a town of Northumberland, 12 miles N. E. of Newcastle.

HARTOGIA, in botany, a genus of the pentandria order, and monœcia class of plants; natural order, Aggregatæ. Calyx five-cleft; petals four, spreading; drupe ovate, inclosing two seeds. There is but one species, viz. *H. capensis*, native of the Cape of Good Hope.

HART-ROYAL, a species of buckthorn-plantain. See **PLANTAGO**.

HARTSHORN, a drug that comes into use many ways, and under many forms. What is used here are the whole horns of the common male deer, which fall off every year. This species is the fallow-deer; but some tell us, that the medicinal hartshorn should be that of the true hart or stag. The salt of hartshorn is a great sudorific, and the spirit has all the virtues of volatile alkalies: it is used to bring people out of faintings by its pungency, holding it under the nose, and pouring down some drops of it in water.

HARTSHORN,

HARTSHORN, CALCINED, or COAL OF HARTSHORN, a very white earth, procured by calcining the horns of harts, in a long continued and strong fire. — This earth is employed in medicine, as an absorbent, and when levigated, is the basis of Sydenham's white decoction, which is commonly prescribed in dysenteries.

HARTSHORN JELLY is nutritive and strengthening, and is sometimes given in diarrhoeas; but a decoction of burnt hartshorn in water is more frequently used for this purpose, and is called *hartshorn-drink*.

HARTSHORN, SPIRIT OF. See **AMMONIA**.

HARTZGEROD, a town of Upper Saxony, in Anhalt Bernburg, 24 miles S. W. of Bernburg.

HARVEST FLY, in zoology, a large four-winged fly of the cicada-kind, very common in Italy, and erroneously supposed to be a grasshopper. See **CICADA**.

HARVEY, Dr. WILLIAM, an eminent English physician of the 17th century, took his degree of M. D. at Cambridge; was afterwards admitted into the college of physicians in London, and was appointed lecturer of anatomy and chirurgery in that college. In these lectures he opened his discovery relating to the circulation of the blood; which, after a variety of experiments, he communicated to the world in his "*Exercitatio anatomica de Motu Cordis et Sanguinis*." He was physician to king James I. and to king Charles I. and adhered to the royal cause. His discovery has eternized his memory. In 1651, he published his "*Exercitationes de Generatione Animalium*," a very curious work. His papers were destroyed during the civil wars. In 1654, he was chosen president of the college of physicians in his absence; but as he could not discharge the duty of that office, he desired them to choose Dr. Pringle. As he had no children, he settled his paternal estate upon the college. In 1653 he built a library, and a museum; and in 1656 he brought the deeds of his estate, and presented them to the college. He was then present at the first feast, instituted by himself, together with a commemoration-speech in Latin, to be spoken on the 18th of October annually in honour of the benefactors to the college; and he appointed a handsome stipend for the orator, and also for the keeper of the library and museum, which are still called by his name. He died in 1657. This great physician had the happiness, in his lifetime, to find the clamours of ignorance, envy, and prejudice, against his doctrine, totally silenced, and to see it universally established. It is of the utmost importance in medicine; as it is perhaps impossible to define health and sickness in fewer words, than that the one is a free, and the other an obstructed, circulation. Dr. Harvey was not only an excellent physician, but an excellent man; his modesty, candour, and piety, were equal to his knowledge; the farther he penetrated into the wonders of nature, the more he venerated the Author of it.

HARVIE, ALEXANDER, a native of Scotland, who at the imminent risk of his life, first introduced the incle-manufacture into Britain. He went over to Holland about 1732, and in spite of the care which the Dutch took to conceal their methods of manufacturing, brought over from Haerlem two of their incle-ooms, and one of their workmen; by whose assistance he established the first incle-manufactory at Glasgow, which has since been copied at Manchester, &c.

HARUSPICES, or ARUSPICES, pretenders to divination by certain signs or omens among the Romans. The Roman haruspices were at first all taken from Hetruria; afterwards young Romans were sent there to be brought up in the science.

HARUSPICY, the art of divination. It consisted in foretelling future events by attending to various circumstances of the victims. 1. It was an ill omen if the victim needed to be dragged to the altar, if it broke its rope, fled away, avoided the stroke, struggled much after it, made a great bellowing, was long a-dying, or bled but little. 2. Presages were drawn from inspecting the noble parts, as the heart, lungs, spleen, and especially the liver. If all these were found, if the top of the liver was large and well made, and if its fibres were strong, it presaged well. 3. They were also drawn from the manner in which the fire consumed the victim. If the flame brightened immediately, was pure and clear, rose out till the victim was consumed, these were happy signs. 4. The smoke also was considered, whether it whirled about in curls, or spread itself to the right or the left, or gave a smell different from the common one of broiled meat. 5. It was a lucky omen if the incense they burned melted all at once, and gave a most agreeable smell.

HARWICH, a populous and well built town of Essex, 72 miles N. E. of London.

HAS, a district of Arabia in Yemen.

Has, the capital of the above district, 40 miles N. of Mocha.

HASBAIN, or HASBEIN, a country in the kingdom of Westphalia.

HASELOE, an island of Denmark, in the Categate, 12 miles from Zealand. Lon. 11. 45. E. Lat. 56. 11. N.

HASLEMERE, a town of Surry, on the edge of the county, next Hampshire, 43 miles from London.

HASLI, a district of the Helvetic Republic, in the canton of Bern, in a fine valley S. E. of lake Brienz, and watered by the Aar; famous for cheese, which the citizens export to Italy.

HASLINDEN, or HASLIGDON, a town of Lancashire, 14 miles N. of Manchester.

HASP AND STAPLES, in Scots law, the symbol commonly used in burgage-tenements for entering and infetting an heir, by delivering into his hands the hasp and staple of the door.

HASSELQUIST, FREDERIC, M. D. an eminent Swedish naturalist, born at Tournalla, in E. Gothland, in 1722, and educated at Upsal, under the great Linnæus. By the advice of that eminent botanist, with the assistance of the University of Upsal, who granted him a salary for the purpose, he set out upon a voyage to Palestine, in summer 1749, with the view of investigating the natural history of that country, and thereby illustrating eastern philology, and elucidating many passages in the Old Testament. In this enterprise he also received much pecuniary aid, by private subscriptions. By the interest of Counsellor Lagerstroem, he obtained a free passage in a Swedish E. Indiaman, to Smyrna; where he arrived in Dec. 1749, and was most hospitably received by M. A. Rydel, the Swedish consul. In Jan. 1750, he set out for Egypt, and spent nine months at Cairo, whence he transmitted to Linnæus some specimens of his discoveries, which were published with great approbation. A collection of 10,000 dollars was then made to enable him to continue his travels and researches. In spring 1751, he passed through Jaffa to Jerusalem; Jericho, &c. returning through Rhodes and Scio to Smyrna. Thus he completed the object of his mission, but unfortunately fell a sacrifice to the heat of the climate, which in his travels through Arabia, had affected his lungs so severely, that he died at Smyrna, Feb. 9th 1752, aged 30. The Turks, with their usual rapacity having seized his collections, were prevented from selling them by the Swedish consul, who wrote home an account of his death and circumstances; whereupon Q. Louisa Ulrica generously sent 14,000 dollars to redeem them; and the whole collection, consisting of numerous antiques, shells, birds, insects, serpents, Arabian MSS. &c. arrived in good preservation at Stockholm, and was lodged in the cabinets of Ulrichsdale, and Drottningholm; duplicates of many of them being also sent to Linnæus at Upsal, who published an account of his deceased friend's voyage and observations, and named a plant after him. See next article.

HASSELQUISTIA, in botany, a genus of the digynia order, and pentandria class of plants; natural order, Umbellata. Fruits quite smooth; seeds of the radius oval, plane, margined, and convex in the middle; those in the disk hemispherical, bladder-shaped. It has two species.

HASSELT, a town of Batavia, in the department of Yssel, and late province of Overijssel; 10 miles E. of Campen.

HASSELT, a town of France, in the department of Ourte, and late territory of Liege; 16 miles N. N. W. of Liege.

HASTA, or HASTA PURA, among medalists, signifies a kind of spear or javelin, not shod or headed with iron; or rather an ancient sceptre, somewhat longer than ordinary, occasionally given to all the gods.

HASTA, in some countries, is a measure or quantity of ground amounting to thirty paces: thus called according to M. Du Cange, from the hasta or rod wherewith it was measured.

HASTATA FOLIA, HASTATED LEAVES. See **BOTANY**.

HASTINGS, a town of Sussex, 64 miles S. E. of London. It is the chief of the cinque-ports: and was formerly obliged to find 21 ships, within 40 days after the king's summons, well furnished and armed for service, and to maintain the crews a fortnight at its own charge. Hastings is remarkable for a battle fought in its neighbourhood, between Harold II. K. of England and William Duke of Normandy, on the 15th Oct. 1066, in which the former was defeated and killed; and by his death William became King.

of England. Hastings lies 24 miles E. of Lewis, and 40 of Bright-helmstone.

HAT, [*hat*, Saxon; *hatt*, German,] a covering for the head, which is generally made of a mixture of Spanish wool with that of hares, kids, rabbits, beaver, &c. Lately, feathers have been usefully employed in the manufacture of this article. Hats are said to have been first used by men, about A. D. 1400, for country wear, riding, &c. But the hatters have a tradition among them, that the origin of their art, at least of that branch of it called felting, is much more ancient. The tradition is, that while St. Clement, the 4th bishop of Rome, was flying from his persecutors, his feet became blistered; in consequence of which he was induced to put wool between the soles of his feet and the sandals which he wore. The consequence was, that in continuing his journey, the wool, by the sweat and motion of his feet, became as completely felted as if wrought on purpose. When he afterwards settled at Rome, he improved the discovery, and hence the origin of felting and hat-making. The hatters in Ireland, as well as in several catholic countries, still hold a festival on St. Clement's day.

HAT-MAKING. The materials being sorted out and mixed in various proportions, and of different qualities, according to the value of the article intended to be made; they proceed to the first process, called bowing. The material, without any previous preparation, is laid upon a platform of wood, or of wire, somewhat more than four feet square, called a hurdle. In the hurdle, if of wood, are longitudinal chinks for the purpose of suffering the dust and other impurities of the stuff, to pass through; a purpose still more effectually answered by the hurdle of wire. The workman is provided with a bow, a bow-pin, a basket, and several cloths. The bow is a pole of yellow deal-wood, between seven and eight feet long, to which are fixed two bridges, somewhat like that which receives the hair in the bow of the violin. Over these is stretched a catgut, about one-12th of an inch in thickness. The bow-pin is a stick with a knob, and is used for plucking the bow-string. The basket is a square piece of osier-work, consisting of open strait bars with no crossing or interweaving. The cloths are linen. Besides these implements, the workman is also provided with brown paper. The bowing commences by shovelling the material towards the right hand partition with the basket, upon which, the workman holding the bow horizontally in his left hand, and the bow-pin in his right, lightly places the bow-string, and gives it a pluck with the pin. The string, in its return, strikes part of the fur, and causes it to rise, and fly partly across the hurdle in a light open form. By repeated strokes, the whole is thus subjected to the bow; and this beating is repeated, till all the original clots or masses of the filaments are perfectly opened and obliterated. The quantity thus treated at once is called a batt, and never exceeds half the quantity required to make one hat. When the batt is sufficiently bowed, it is ready for hardening; which term denotes the first commencement of felting. The prepared material being evenly disposed on the hurdle, is first pressed down by the convex side of the basket, then covered with a cloth, and pressed successively in its various parts by the hands of the workman. This pressure brings the hairs against each other, and multiplies their points of contact; the agitation of them gives to each hair a progressive motion towards the root; by means of this motion the hairs are twisted together, and the lamellæ of each hair, by fixing themselves to those of other hairs which happen to be directed the contrary way, keep the whole in that compact state which the pressure makes it acquire. In proportion as the mass becomes compact, the pressure of the hands should be increased; not only to make it more close, but also to keep up the progressive motion and twisting of the hairs, which then takes place with greater difficulty: but throughout the whole of this operation, the hairs fix themselves only to each other, and not to the cloth with which they are covered, the fibres of which are smooth, and have no disposition to felting. See **HAIR**. "In a short time the stuff acquires sufficient firmness to bear careful handling. The cloth is then taken off, and a sheet of paper, with its corners doubled in, so as to give it a triangular outline, is laid upon the batt, which last is folded over the paper as it lies, and its edges, meeting one over the other, form a conical cap. The joining is soon made good by pressure with the hands on the cloth. Another batt, ready hardened, next laid on the hurdle, and the cap here mentioned placed upon it, with the joining downwards. This last batt being also folded up, will consequently have its place of junction diametri-

cally opposite to that of the inner felt, which it must therefore greatly tend to strengthen. The principal part of the hat is thus put together, and now requires to be worked with the hands a considerable time upon the hurdle, the cloth being also occasionally sprinkled with clear water. During the whole of this operation, which is called basoning, the article becomes firmer and firmer, and contracts in its dimensions. It may easily be understood, that the chief use of the paper is to prevent the sides from felting together. The hat thus basoned, they remove it to a large kind of receiver or trough, resembling a mill-hopper, going sloping or narrowing down from the edge or rim to the bottom, which is a copper-kettle filled with water and grounds, kept hot for that purpose. On the descent or sloping side, called the plank, the basoned hat, being first dipped in the kettle, is laid; and here they proceed to work it, by rolling and unrolling it again and again, one part after another, first with the hand, and then with a little wooden roller, taking care to dip it from time to time, till at length, by thus fulling and thickening it four or five hours, it is reduced to the extent or dimensions of the hat intended. The hat thus wrought, they proceed to give it the proper form, which is done by laying the conical cap on a wooden block, of the intended size of the crown of the hat, and then tying it round with a packthread: after which, with a piece of iron or copper bent for that purpose, and called a stamper, they gradually beat or drive it down all round, till it has reached the bottom of the block, and thus is the crown formed; what remains at bottom below the string being the brim. The hat being now set to dry, they proceed to singe it, by holding it over a flare of straw or the like; then it is pounced, or rubbed over with pumice, to take off the coarser knap; then rubbed over afresh with seal-skin to lay the knap a little finer; and lastly, carded with a fine card to raise the fine cotton, with which the hat is afterwards to appear. Things thus far advanced, the hat is thus sent, upon its block, and tied about with a packthread as before, to be dyed. The dye being completed, the hat is returned to the hatter, who proceeds to dry it, by hanging it in the top or roof of a stove or oven, at the bottom of which is a charcoal-fire: when dry, it is to be stiffened, which is done with melted glue, or gum, senegal applied thereon by first smearing it, and beating it over with a brush, and then rubbing it with the hand. The next thing is to steam it on the steaming-bason, which is a little hearth or fire-place. When steamed sufficiently, and dried, they put it again on the block, and brush and iron it on a table or bench for the purpose, called the stall-board; this they perform with a sort of irons like those commonly used in ironing linen, and heated like them, which being rubbed over and over each part of the hat with the assistance of the brush, smooths and gives it a gloss, which is the last operation; nothing now remains but to clip the edges even with scissors, and sew a lining to the crown.

HATS, METHOD OF DYEING. According to Dr. Lewis, the best proportion of ingredients for dyeing hats is as follows: 100 lb. of logwood, 12 lb. of gum, and 6 lb. of galls, are boiled in a proper quantity of water for some hours; after which, about 6 lb. of verdigris and 10 of green vitriol are added, and the liquor kept just simmering, or of a heat a little below boiling: 10 or 12 doz. of hats are immediately put in, each on its block, and kept down by cross-bars for about an hour and an half: they are then taken out and aired, and the same number of others put in their room. The two sets of hats are thus dipped and aired alternately, eight times each; the liquor being refreshed each time with more of the ingredients, but in less quantity than at first. This process (says Dr. Lewis) affords a very good black on woollen and silk stuffs as well as on hats, as we may see in the small pieces of both kinds which are sometimes dyed by the hatters.

HATS are also made for women's wear, not only of the above stuffs, but of chips, straw, or cane, by plaiting, and sewing the plaits together; beginning with the centre of the crown, and working round till the whole is finished. They are also wove and made of horse-hair, silk, &c.

HATA, a large river of S. America, in Chili.

HACHEL, or **HITCHEL**, a tool with which flax and hemp are combed into fine hairs: It consists of long iron-pins, or teeth, regularly set in a piece of board. There are several sorts of hatchels, each finer than the other, with which flax and hemp are prepared for spinning.

HATCHES, in a ship, a kind of trap-doors between the main-
mast

mast and fore-mast, through which all goods of bulk are let down into the hold.

HATCHES, COAMINGS OF THE, are the pieces of timber, or planks, which raise up the hatches, when they are made higher than the rest of the deck.

HATCHES also denote flood-gates set in a river, &c. to stop the current of the water, particularly certain dams or mounds made of rubbish, clay, or earth, to prevent the water that issues from the stream-works and tin-washes in Cornwall, from running into the fresh rivers.

HATCHES, in mining, a term used in Cornwall, to express any of the openings of the earth either into mines or in search of them.

HATCH-WAY, the place where the hatches are. Thus, to lay a thing in the hatch-way, is to put it so, that the hatches cannot be come at, or opened.

HATCHET, [*hache, hachette*, Fr. *ascia*, Latin,] a small axe.

HATCHETS have a basil-edge on the left side, and a short handle, being used with one hand. They are used by various artificers, particularly in hewing wood.

HATCHING, the maturing fecundated eggs, whether by the incubation and warmth of the parent bird, or by artificial heat, so as to produce young chickens alive. The art of hatching chickens by means of ovens has long been practised in Egypt, chiefly in a village named Berme, and its environs. About the beginning of autumn the natives scatter themselves all over the country: where each undertakes the management of an oven. These ovens are of different sizes, but, in general, they contain from 40 to 80,000 eggs. The number of ovens is about 386, and they usually keep them working for about six months: as, therefore, each brood takes up in an oven, as under a hen, only 21 days, it is easy in every one of them to hatch eight different broods of chickens. Every Bermean is under the obligation of delivering to the persons who trusts him with an oven, only two-thirds of as many chickens as there have been eggs put under his care; and he is a gainer by this bargain, as more than two-thirds of the eggs usually produce chickens. In calculating the number of chickens thus annually hatched in Egypt, it has been supposed that only two-thirds of the eggs are hatched, and that each brood consists of at least 30,000 chickens. Hence it appears, that the ovens of Egypt give life yearly to at least 92,640,000 of these animals. This useful and advantageous method of hatching eggs was discovered in France by the ingenious Mr. Reaumur; who, by a number of experiments, reduced the art to fixed principles. He found that the heat necessary for this purpose is nearly the same with that marked 32 on his thermometer, or 96 on Fahrenheit's. This degree of heat is nearly that of the skin of the hen, and of all other domestic fowls, and probably of all other kinds of birds. The degree of heat, which brings about the development of the cygnet, the gosling, and the turkey-pout, is the same as that which fits for hatching the canary songster, and in all probability, the smallest humming-bird: the difference is only in the time during which this heat ought to be communicated to the eggs of different birds. It will bring the canary-bird to perfection in 11 or 12 days, while the turkey-pout will require 27 or 28. After many experiments, Mr. Reaumur found, that stoves heated by means of a baker's oven, succeeded better than those made hot by layers of dung: and the furnaces of glass-houses and those of the melters of metals, by means of pipes to convey heat into a room, might, no doubt, be made to answer the same purpose. As to the form of the stoves, no great nicety is required. A chamber over an oven will do very well. Nothing more is necessary but to ascertain the degree of heat, by melting a lump of butter of the size of a walnut, with half as much tallow, and putting it into a phial. This serves to indicate the heat with sufficient exactness: for when it is too great, this mixture will become as liquid as oil; and when the heat is too small, it will remain fixed in a lump: but it will flow like a thick syrup, upon inclining the bottle, if the stove be of a right temper. Great attention therefore should be given to keep the heat always at this degree, by letting in fresh air if it be too great, or shutting the stove more close if it be too small; and that all the eggs in the stove may equally share the irregularities of the heat, it will be necessary to shift them from the sides to the centre; and thus to imitate the hens, who are frequently seen to make use of their bills, to push to the outer parts those eggs that were

nearest to the middle of their nests, and to bring into the middle such as lay nearest the sides. Mr. Reaumur has invented a sort of low boxes, without bottoms, and lined with furs. These, which he calls artificial parents, not only shelter the chickens from the injuries of the air, but afford a kindly warmth, so that they take the benefit of their shelter as readily as they would have done under the wings of a hen. After hatching, it will be necessary to keep the chickens, for some time, in a room artfully heated and furnished with these boxes; but afterwards they may be safely exposed to the air in the court-yard, in which it may not be amiss to place one of these artificial parents to shelter them, if there should be occasion for it. They are generally a whole day after being hatched, before they take any food at all. A few crumbs of bread may then be given them for a day or two, after which they will pick up insects and grass for themselves. But to save the trouble of attending them, capons may be taught to watch them in the same manner as hens do. Mr. Reaumur says he has seen above 200 chickens at once, all led about and defended only by three or four capons. Nay, cocks may be taught to perform the same office; which they, as well as the capons, will continue to do all their lives after.

HATCHING, or HACHING, in designing, &c. the making of lines with a pen, pencil, graver, or the like; and intersecting or going across those lines with others drawn a contrary way, is called counter-hatching. The depths and shadows of draughts are usually formed by hatching. Hatching is of singular use in heraldry, to distinguish the several colours of a shield, without being illuminated: thus, gules or red is hatched by lines drawn from the top to the bottom; azure by lines drawn across the shield; and so of other colours.

HATCHMENT, in heraldry, is the coat of arms of a person dead; usually placed on the front of a house, whereby may be known what rank the deceased person was of when living; the whole distinguished so as to enable the beholder to know whether he was a bachelor, married man, or widower; with the like distinctions for women.

HATFIELD, or BISHOP's HATFIELD, a town of Hertfordshire, 1½ miles N. of London.

HATFIELD, a town in the W. riding of Yorkshire, four miles from Doncaster, with its chase, famous for deer-hunting.

HATFIELD BROAD-OAK, HATFIELD REGIS, or KING's HATFIELD, a town of Essex, seated on a branch of the Lea, 29 miles N. N. E. of London.

HATHERLEY, a town of Devonshire, 28 miles W. N. W. of Exeter.

HATTEMISTS, in ecclesiastical history, a modern Dutch sect, so called from Pontian Van Hattem, a minister in Zealand, towards the close of the 17th century, who being addicted to the sentiments of Spinoza, was degraded from his pastoral office. The Verschorists and Hattemists resemble each other in their religious systems, though they never formed one communion. The founders of these sects deduced from the doctrine of absolute decrees a system of uncontrollable necessity; they denied the difference between moral good and evil, and the corruption of human nature: whence they concluded, that mankind were under no obligation to correct their manners, improve their minds, or obey the divine laws; that the whole of religion consisted not in acting, but in suffering; and that all the precepts of Jesus Christ are reducible to this one, that we bear with cheerfulness and patience the events that happen to us through the divine will, and make it our constant and only study to maintain a permanent tranquillity of mind.

HATTERAS, CAPE, a cape on the coast of N. Carolina. Lon. 75. 54. W. Lat. 35. 8. N.

HATTINGEN, a town of Germany, in the circle of Westphalia, and county of Mark, 16 miles N. E. of Dusseldorp.

HAVANNAH, a city and sea-port town of the island of Cuba, on the N. coast, opposite to Florida. It is famous for its harbour, which is in every respect one of the best in the West Indies, and perhaps in the world. Lat. 23° 11' 52" N. Lon. 82° 8' 36" W. from Greenwich.

HAVANT, a town of Hampshire, 9 miles W. of Chichester.

HAVEL, a river which rises from a lake in Mecklenburg, and runs N. into the Elbe, near Werben, in Brandenburg.

HAVELBERG, a town of Upper Saxony, in Brandenburg, seated on the Havel, 37 miles N. W. of Brandenburg.

HAVEN,

HAVEN, [*haven*, Dutch; *havre*, French,] a port; a harbour; a station for ships. See **HARBOUR**, and **PORT**.

HAVER is a common word in the northern counties for oats; as, *haver* bread for oatmeal bread; perhaps properly *aven*, from *avena*, Lat.

HAVERFORD WEST, a neat, well-built and populous town of S. Wales, in Pembrokeshire; 256 miles from London.

HAVERHILL, a town of New Hampshire, capital of Grafton county, 32 miles above Dartmouth college, and 496 N. E. of Philadelphia.

HAVERILL, a town of England, partly in Essex, and partly in Suffolk, 20 miles S. E. of Cambridge.

HAUL, among seamen, implies to pull a single rope, without the assistance of blocks or other mechanical powers. When a rope is otherwise pulled, as by the application of tackles, or the connection with blocks, &c. the term is changed into *bowing*.

HAUL THE WIND, is to direct the ship's course nearer to that point of the compass from which the wind arises. Thus, supposing a ship to sail S. W. with the wind northerly, and some particular occasion requires to haul the wind more westward; to perform this operation, it is necessary to arrange the sails more obliquely with her keel; to brace the yards more forward, by slackening the starboard and pulling in the larboard braces, and to haul the lower sheets further aft; and, finally, to put the helm a-port, *i. e.* over to the larboard side of the vessel. As soon as her head is turned directly to the westward, and her sails are trimmed accordingly, she is said to have hauled the wind four points; that is to say, from S. W. to W. She may still go two points nearer to the direction of the wind, by disposing her sails according to their greatest obliquity, or, in the sea-phrases, by trimming all sharp; and in this situation she is said to be close-hauled, as sailing W. N. W.

HAULM, **HALM**, or **HAWN**, among farmers, signifies the stem or stalk of corn, pease, beans, &c. from the root to the ear.

HAUNCH, or **HANCH**, that part of the body between the last ribs and the thigh.

HAUNCHES OF A HORSE are too long, if when standing in the stable he limps, with his hind-legs farther back than he ought; and when the top of his tail is not in a perpendicular line to the tip of his hocks, as it always is in horses whose haunches are of a just length.

HAVRE DE GRACE, a sea-port town of France, in the department of Lower Seine and late province of Normandy, on the English Channel, 45 miles W. of Rouen, and 12 N. W. of Paris.

HAURIANT, in heraldry, a term peculiar to fishes; signifying their standing upright, as if refreshing themselves by sucking in the air.

HAUTBOY, a wind-instrument, shaped much like the lute; only it spreads and widens towards the bottom, and is sounded through a reed. The treble is two feet long; the tenor goes a fifth lower when blown open; it has only eight holes; but the bass, which is five feet long, has 11. The name is French, *haut bois*, *q. d.* high wood; and is given to this instrument because the tone of it is higher than that of the violin.

HAUTBOY STRAWBERRY. See **FRAGRARIA**.

HAUTE FEUILLE, JOHN, an ingenious mechanic, born at Orleans in 1647. Though he was an ecclesiastic, and enjoyed several benefices, he applied almost his whole life to mechanics, in which he made a great progress. He had a particular taste for clock-work, and made several discoveries in it that were of singular use. He found out the secret of moderating the vibration of the balance by means of a small steel-spring, which has since been made use of. This discovery he laid before the members of the Academy of Sciences in 1674; and these watches are called pendulum-watches, not that they have real pendulums, but because they nearly approach to the justness of pendulums. M. Huygens perfected this happy invention; but having declared himself the inventor, and obtained from Lewis XIV. a patent for making watches with spiral springs, the abbé Feuille opposed the registering of this privilege, and published a piece on the subject against M. Huygens. He wrote a great number of other pieces, most of which are small pamphlets consisting of a few pages, but very curious; as, 1. The perpetual Pendulum; 4to. 2. New Inventions; 4to. 3. The Art of Breathing under Water, and the Means of preserving a Flame shut up in a small Place. 4. Reflec-

tions on Machines for raising Water. 5. On the different Sentiments of Malebranche and Regis, relating to the Appearance of the Moon when seen in the Horizon. 6. The magnetic Balance. 7. A Placet to the King on the Longitude. 9. A new System on the Flux and Reflux of the Sea. 10. The Means of making sensible Experiments that prove the Motion of the Earth; and many other pieces. He died in 1724.

HAUTE-RIVE, a town of France, in the department of Upper Garonne, and late province of Languedoc, 10 miles S. of Toulouse.

HAW, or **HAUGH**, in farriery, is a spongy excrescence in the inner corner of the eyes of horses, or other cattle, and which, if not timely removed, will occasion total blindness. It arises from gross humours, and is known by the watering of the eye, and the opening of the lower side.

HAWKER, [from *hock*, Germ.] one who sells his wares by proclaiming them in the street.

HAWKERS anciently were fraudulent persons, who went from place to place buying and selling brass, pewter, and other merchandize, which ought to be uttered in open market. In this sense the word is mentioned, 25 Hen. VIII. cap. 6, and 33, cap. 4. The appellation seems to have arisen from their uncertain wandering, like those who, with hawks, seek their game where they can find it. The term is now used as synonymous with pedlar; a person who travels about the country selling wares. Every hawker must take out an annual licence, for which he must pay 4*l.* and if he travel with a horse, ass, or mule, for every one of them 8*l.* If he travel without a licence, or contrary to it, he forfeits for every offence to the informer, and the poor of the parish where discovered, 10*l.* The acts relating to hawkers do not extend to makers of goods or their agents; or to those who sell goods in fairs or markets; to the sellers of fish, fruit, or other victuals; nor to the venders of books and newspapers: 9 and 10 W. cap. 27. 3 and 4 Anne, cap. 4. But hawkers shall not, by virtue of such licence, sell or offer to sale, any tea or spirituous liquors, though with a permit, under the penalty of having the same seized, and imprisonment and prosecution of the offender, 9 Geo. II. cap. 35. Hawkers who were licensed on June 23, 1785, may set up any business in the place where they are resident inhabitants, brought up thereto. Additional duties, are, however, imposed upon hawkers, by acts, 29 Geo. III. c. 26, and 35 Geo. III. c. 91.

HAWKING, the art, or exercise, of taking wild fowl by means of hawks. The method of reclaiming, manning, and bringing up, a hawk to this exercise, is called **FALCONRY**, which see.

HAWKSHEAD, a town of Lancashire, 38 miles N. of Lancaster, and 273 N. N. W. of London.

HAWKWEED. See **CREPIS**, and **HIERACIUM**.

HAWS, a river of N. Wales, in Montgomeryshire.

HAWS, a river of S. Wales, in Radnorshire.

HAWS, or **HAWS-WATER**, a lake of Westmoreland, W. of Penrith, three miles long, and half a mile broad.

HAWSE, or **HAUSE**, implies the situation of the cables before the ship's stem, when she is moored with two anchors out from forward, *viz.* one on the starboard and the other on the larboard bow. Hence it is usual to say, she has a clear hawse, or a foul hawse. It also denotes any small distance a-head of a ship, or between her head and the anchors employed to ride her, as He has anchored in our hawse, The brig fell athwart our hawse, &c. A ship is said to ride with a clear hawse, when the cables are directed to their anchors, without lying athwart the stem; or crossing, or being twisted round each other, by the ship's winding about, according to the change of the wind, tide, or current. A foul hawse, on the contrary, implies that the cables lie across the stem, or bear upon each other, so as to be rubbed and chafed by the motion of the vessel. The hawse accordingly is foul, by having either a cross, an elbow, or a round turn. If the larboard-cable lying across the stem, points out on the starboard-side, while the starboard-cable at the same time grows out on the larboard-side, there is a cross on the hawse. If, after this, the ship, without returning to her former position, continues to wind about the same way, so as to perform an entire revolution, each of the cables will be twisted round the other, and then directed out from the opposite bow, forming what is called a round turn. An elbow is produced when the ship stops in the middle of that revolution, after having had a cross: or, in other words, if she rides with her head north-

ward with a clear hawse, and afterwards turns quite round so as to direct her head northward again, she will have an elbow.

HAWSE-PIECES, the foremost timbers of a ship, whose lower ends rest on the knuckle-timber, or the foremost of the cant-timbers. They are generally parallel to the stem, having their upper ends sometimes terminated by the lower part of the beak-head; and otherwise by the top of the bow, particularly in small ships and merchantmen.

HAWTHORN. See **CRATÆGUS**.

HAWTHORN, AMERICAN. See **VIBURNUM**.

HAY, grass cut and dried for fodder. The time of mowing grass for hay must be regulated according to its growth and ripeness; nothing being more prejudicial to the crop than mowing it too soon, because the sap is not then fully come out of the root, and when made into hay, the grass shrinks away to nothing. It must not, however, be let stand too long till it have shed its seeds. When the tops of the grass look brown, and begin to bend down, and the red honeysuckle flowers begin to wither, it is ripe for mowing. See **HUSBANDRY**.

HAY, in geography, a town of S. Wales in Brecknockshire. Lon. 3. 4. W. Lat. 51. 59. N.

HAYE, a town of France, in the department of Indre and Loire, on the Creuse; 25 miles S. of Tours.

HAYES, CHARLES, Esq. a person of great erudition and modesty. He was born in 1678, and became distinguished in 1704, by "A Treatise on Fluxions," in folio; the only work to which he ever set his name. In 1710, came out a quarto pamphlet of nineteen pages, entitled "A New and Easy Method to find out the Longitude, from observing the Altitudes of the Celestial Bodies;" and in 1723, "The Moon," a Philosophical Dialogue; tending to shew, that the moon is not an opaque body, but has original light of her own. He principally had the management of the late Royal African company. To a skill in the Greek and Latin, as well as the modern languages, he added the knowledge of the Hebrew: and published several pieces relating to the translation and chronology of the scriptures. He died at London, December 28, 1760, in his 82d year. The title of his posthumous works runs thus: *Chronographiæ Asiaticæ et Egyptiacæ Specimen*; in quo, 1. *Origo Chronologiæ lxx. Interpretum Investigatur*. 2. *Conspectus Totius Operis Exhibitur*, 8vo.

HAZAEEL, [חזקאל, Heb. *z. e.* seeing God,] an officer belonging to Benhadad king of Syria, who caused that prince to be put to death, and reigned in his stead. He defeated Joram, Jehu, and Jehoabaz, kings of Israel; and after his death, was succeeded by Benhadad his son, B. C. 889.

HAZARD, a game on dice, without tables, is very properly so called, since it speedily enriches a man or ruins him. It is played only with two dice without tables. See **GAMING**.

HAZEBROUC, a town of France, in the department of the North, 19½ miles W. of Lille.

HAZEL, or **HAZLE**, in botany. See **CORYLUS**. The kernels of the fruit have a mild, farinaceous, oily taste, agreeable to most palates. A kind of chocolate has been prepared from them, and there are instances of their having been formed into bread. The oil expressed from them is little inferior to the oil of almonds; and is used by painters and by chemists for receiving and retaining odours.

HEAD. See **ANATOMY**.

HEADACH, a most troublesome sensation in the head produced by various causes, and attended with different symptoms, according to its different degrees, and the place where it is seated. See **MEDICINE**.

HEAD-BOROUGH, or **HEAD-BOROW**, is the chief of the frank pledge, and had anciently the principal direction of those within his own pledge. This officer is now called a high constable. The head-borow was the chief of ten pledges: the other nine were called hand-borows, or *plegii manuales*. See **CONSTABLE**.

HEAD-FAST, a rope employed to fasten a ship to a wharf, chain, or buoy, or to some other vessel along-side.

HEADFORD, a town of Ireland, 12 miles N. of Galway.

HEADMOULD-SHOT, a disease wherein the sutures are so close locked together, as to compress the internal parts, the meninges, or even the brain. It is supposed to admit of no cure from medicine, unless room could be given by manual operation or a division of the sutures. It is the opposite of the horse-shoe-head.

HEADON, or **HEYDON**, a borough of Yorkshire, in the East Riding, 8 miles E. of Hull.

HEAD-PENCE, an exaction of a certain sum formerly collected by the sheriff of Northumberland from the inhabitants of that county, without any account to be made to the king. It was abolished by stat. 23 Hen. VI. cap. 7.

HEAD-ROPE, that part of the bolt-rope which terminates any of the principal sails on the upper edge, which is accordingly sewed thereto.

HEAD-SAILS, a general name for all those sails which are extended on the fore-mast and bowsprit, and employed to command the fore-part of the ship: such are the fore-sail, fore-top-sail, fore-top-gallant sail, jib, fore-stay-sail, and the sprit-sail with its top-sail. This term is used in opposition to after-sails, viz. all those which are extended on the mizen-mast, and on the stays between the mizen and main-masts.

HEAD-TIN, in metallurgy, is a preparation of tin-ore toward the fitting it for working into metal. When the ore has been pounded and twice washed, that part of it which lies uppermost, or makes the surface of the mass in the tub, is called the head-tin.

HEAD TO WIND; the situation of a ship or boat, when her head is turned to windward.

HEAD-WAY, the motion of advancing at sea. It is generally used when a ship first begins to advance; or when it is doubtful whether she is in a state of rest or motion. It is in both senses opposed to retreating, or moving with the stern foremost.

HEALFANG, **HEALSFANG**, or **HALSFANG**, [from *halp*, neck, and *pangen*, to contain, Sax.] in the ancient English customs, signifies collistrigium, or the punishment of the pillory: *Pana scilicet qua alicui collum stringatur*.

HEALFANG is also taken for a pecuniary punishment or mulct, to commute for standing in the pillory; and is to be paid either to the king or the chief lord. *Qui falsum testimonium dedit, reddat regi vel terræ domino healfang*.

HEALING, in its general sense, includes the whole process of curing a disorder, and restoring health. In this sense medicine is defined the art of healing. In its more restrained sense, as used in surgery, &c. healing denotes the uniting or consolidating the lips of a wound or ulcer. The medicines proper for this intention are called incarnatives, agglutinatives, vulneraries, &c.

HEALING, in architecture, denotes the covering the roof of a building; whether with lead, tiles, slates, Horsham stones, shingles, reeds, or straw.

HEALTH, [from *heel*, Sax.] a right disposition of the body, and of all its parts; consisting in a due temperature, a right conformation, just connection, and ready and free exercise of all the vital functions. Health admits of latitude, as not being the same in all subjects, who may yet be said to enjoy health. That part of medicine which shews the means of preserving health, is termed hygiene. See **MEDICINE**. The Greeks and Romans deified health. See **HYGIEA** and **SALUS**.

HEALTH, [*heel*, Sax.] is a proper disposition of the several constituent parts of the body, by which they are enabled to perform their respective functions without any impediment. The continuance of health depends chiefly on what has been professionally called, the six non-naturals; namely, air, food, exercise, the passions, evacuation, and retention; sleep and waking. Moderation, however, in the strictest sense of the word, is equally essential to the preservation of health, as a pure air, and wholesome food. Cleanliness, too, ought by no means to be neglected; for an unclean person very seldom enjoys good health. Hence, frequent washing of the skin is of the first importance; and we are fully persuaded, that most of the diseases, with which the lower classes of people are affected, especially in crowded neighbourhoods, originate from the filthy state which is but too evident in many of their wretched habitations. With respect to those persons who propose to reside in hot climates, we shall state only a few simple rules, by an attention to which their health may be effectually preserved. 1. Abstain from all excess in spirituous liquors. 2. Avoid with the utmost care the evening dews, or wetting of the feet on the approach of night; as fatal sore throats not unfrequently arise from this source. Should the feet, however, have been wetted by any accident, let the whole body be speedily immersed into cold water. 3. Bathe every morning in the sea, or, if possible,

possible, in sea-water; but, where that cannot be procured, dissolve an ounce of salt in a basin of water, and wash the skin with the solution, after which put on the clothes without drying the skin. This operation strengthens the muscular fibres, and covers the skin with a kind of saline crust, which, in the opinion of Dr. Hales, effectually prevents all febrile infections. With these precautions, he asserts, a person of a sound constitution may enjoy as good a state of health in the hottest as in the most temperate climates.

HEARING, a sensation, whereby, from a due motion impressed on the fibrillæ of the auditory nerve, and communicated thence to the sensory, the mind perceives and gets the idea of sounds. See **ANATOMY** and **ACOUSTICS**.

HEART, [*heort*, Sax. *hertz*, German,] the muscle which by its contraction and dilatation propels the blood through the course of circulation, and is therefore considered as the source of vital motion. See **ANATOMY**.

HEART, EXPERIMENTS TO ASCERTAIN THE FORCE OF THE BLOOD IN THE. Physiologists and Anatomists have from time to time attempted to make estimates of the force of the blood in the heart and arteries; but have differed as widely from each other, as they have from the truth, for want of sufficient data. This set the ingenious Dr. Hales upon making proper experiments, to ascertain the force of the blood in the veins and arteries of several animals. If, according to Dr. Keil's estimate, the left ventricle of a man's heart throws out in each systole an ounce or 1.638 cubic inches of blood, and the area of the orifice of the aorta be = 0.4187, then dividing the former by this, the quotient 3.9 is the length of the cylinder of blood which is formed in passing through the aorta in each systole of the ventricle; and in the 75

pulses of a minute, a cylinder of 292.5 inches in length will pass: this is at the rate of 1462 feet in an hour. But the systole of the heart being performed in one-third of this time, the velocity of the blood in that instant will be thrice as much, viz. at the rate of 4386 feet in an hour, or 73 feet in a minute. And if the ventricle throws out one ounce in a pulse, then in the 75 pulses of a minute, the quantity of blood will be equal to 4.4 pounds 11 ounces, and, in 34 minutes, a quantity equal to a middle-sized man, viz. 158 pounds will pass through the heart. But if, with Dr. Harvey and Dr. Lower, we suppose 2 ounces of blood, that is, 3.276 cubic inches, to be thrown out at each systole of the ventricle, then the velocity of the blood in entering the orifice of the aorta will be double the former, viz. at the rate of 146 feet in a minute, and a quantity of blood equal to the weight of a man's body will pass in half the time, viz. 17 minutes. If we suppose, what is probable, that the blood will rise $7 + \frac{1}{2}$ feet high in a tube fixed to the carotid artery of a man, and that the inward area of the left ventricle of his heart is equal to 15 square inches, these, multiplied into $7 + \frac{1}{2}$ feet, give 1350 cubic inches of blood, which presses on that ventricle, when it first begins to contract a weight equal to 15.5 pounds. What Dr. Hales thus calculated from supposition, with regard to mankind; he actually experimented upon horses, dogs, fallow-does, &c. by fixing tubes in orifices opened in their veins and arteries; by observing the several heights to which the blood rose in these tubes as they lay on the ground; and by measuring the capacities of the ventricles of the heart and orifices of the arteries. And, that the reader may the more readily compare the said estimates together, he has given a table of them, ranged in the following order:

HEART, TABLE OF THE VELOCITY, &c. OF THE BLOOD IN THE, OF DIFFERENT ANIMALS.

The several animals.	Weight of each.	Height of the blood in the tube from the jugular vein.	Height of the blood in tubes fixed to arteries.	Capacity of the left ventricle of the heart.	Area of the orifice of the aorta.	Velocity of the blood in the aorta.	Quantities of blood equal to the weight of the animal, in what time.	How much in a minute.	Weight of the blood sustained in the left ventricle contracting.	N° of pulses in a minute.	Area of transverse section of descending aorta.	Area of the transverse section of ascending aorta.
	Pounds.	Inches.	Feet. Inches.	Cubic inches.	Square inches.	Feet and inches in a minute.	Minutes.	Pounds.	Pounds.		Square inches.	Square inches.

HEARTH-MONEY, or CHIMNEY-MONEY, a duty to the crown on houses. By stat. 14. Char. II. cap. 2, every fire-hearth, and stove of every dwelling or other house, within England and Wales (except such as pay not to church and poor), was chargeable with 2s. per annum, payable at Michaelmas and Lady-day to the king and his heirs and successors, &c. This tax, being much complained of as burdensome to the people, has been since taken off, and others imposed in its stead; among which that on windows has by some been esteemed almost equally grievous.

HEART'S-EASE. See VIOLA.

HEART-SEED. See CARDIOSPERMUM.

HEAT, [*heat, hat*, Saxon; *heete*, Danish,] in physiology, has a double meaning; being put either for that peculiar sensation which is felt on the approach of burning bodies, or for the cause of that sensation; in which last sense it is synonymous with fire, or that substance now called caloric. See CALORIC, CHEMISTRY, COMBUSTION, and ELECTRICITY.

HEAT, INTERNAL, OF THE EARTH. That there is a very considerable degree of heat always felt in digging to great depths in the earth, is agreed upon by all naturalists: but the quantity of this heat hath seldom been measured in any part; nor is it known whether in digging to an equal depth in different parts of the earth, the heat is found always the same. In digging mines, wells, &c. they find that at a little depth below the surface it is cold. A little lower it is colder still, as being beyond any immediate influence of the sun's rays; inasmuch that water will freeze almost at any season of the year: but when we go to the depth of 40 or 50 feet, it begins to grow warm, so that no ice can bear it; and then the deeper we go, still the greater the heat, until at last respiration grows difficult, and the candles go out. This heat of the earth has been variously explained. Some suppose an immense body of fire lodged in the centre of the earth, which they consider as a central sun, and the great principle of the generation, vegetation, nutrition, &c. of fossil and vegetable bodies. But Mr. Boyle, who had been at the bottom of some mines himself, suspects that this degree of heat, at least in some of them, may arise from the peculiar nature of the minerals generated therein. In proof of this, he instances a mineral of a vitriolic kind, dug up in large quantities in many parts of England, which by the bare effusion of common water will grow so hot, that it will almost take fire.

HEAT, NOXIOUS EFFECTS OF IMMODERATE. Great heats are rather the remote, than the immediate cause of epidemical diseases, by relaxing the fibres, and disposing the juices to putrefaction; especially among soldiers and persons exposed the whole day to the sun; for the greatest heats are seldom found to produce epidemical diseases, till the perspiration is stopped by wet clothes, fogs, dews, damps, &c. and then some bilious or putrid distemper is the certain consequence, as fluxes and ardent intermitting fevers. Sometimes, however, heats have been so great as to prove the more immediate cause of particular disorders; as when centinels have been placed without cover or frequent reliefs in scorching heats; or when people imprudently lie down and sleep in the sun. All these circumstances are apt to bring on distempers, varying according to the season of the year. In the beginning of summer, they produce inflammatory fevers; and in autumn, remitting fevers or dysenteries. To prevent, therefore, the effects of immoderate heats, commanders have found it expedient so to order the marches, that the men come to their ground before the heat of the day; and to give strict orders, that none of them sleep out of their tents, which, in fixed encampments, may be covered with boughs to shade them from the sun. It is likewise a rule of great importance to have the soldiers exercised before the cool of the morning is over; as thus not only the sultry heats are avoided, but the blood being cooled, and the fibres braced, the body will be better prepared to bear the heat of the day. Lastly, in very hot weather, it has often been found proper to shorten the centinel's duty, when obliged to stand in the sun.

HEAT OF ANIMALS. Of the natural heat of animals, there are various degrees; some preserving a heat of 100° or more in all the different temperatures of the atmosphere; others keeping only a few degrees warmer than the medium which surrounds them; and in some of the more imperfect animals, the heat is scarcely one degree above that of the air or water in which they live. The phenomenon of animal heat has, from the earliest ages, been the subject of philosophical discussion; and many hypotheses have

been framed to account for it. According to Dr. Crawford, who has made accurate experiments on this subject, the blood which circulates through the lungs absorbs oxygen in the act of respiration, by means of which a portion of the carbon which it contains is acidified and carried off in the elastic state. After this, and perhaps other changes, the fluid passes through the arteries to the extreme vessels, depositing in some manner the elementary parts or principles of animal matter during the act of nutrition, in which state of still further change the blood returns by the veins, and again passes through the course of circulation. From his experiments on the capacities of arterial and venous blood, Dr. Crawford found the capacity of the former for heat to be 1.030, and that of the latter only 0.892, whence he concludes, that though heat must be given out in consequence of the diminished capacity of the combined oxygen absorbed by respiration, yet the increased capacity of the arterial blood will prevent its becoming sensible immediately in the lungs; instead of which, it will be given out at the smaller ramifications where the blood becomes changed in its nature, and in its capacity for heat by its conversion to the venous state. It has also been established by the experiments of the same philosopher, that the process of absorption of oxygen is less in a higher than in a low temperature; the difference between the arterial and venous blood being at the same time less, and consequently the augmentation of temperature in the animal less considerable. This law of the animal economy, assisted by the increased evaporation, and by the slow conducting power of an animal body, and perhaps by the permanency of the enlarged capacity, seems sufficient to account for the power which animals possess of maintaining their natural temperature without any remarkable change in an atmosphere greatly heated, as was shewn in the experiments of Fordyce and Blagden. (See Philos. Trans. 1775.) However this subject will admit of farther consideration and investigation.

HEAT OF THE ATMOSPHERE. The mercury seldom falls under 16° in Fahrenheit's thermometer; but we are apt to reckon it very cold at 24°, and it continues cold to 40° and a little above. However, such colds have been often known as bring it down to 0° the beginning of the scale, or nearly the cold produced by a mixture of snow and salt, often near it, and in some places below it. Thus, the degree of the thermometer has been observed at various times and places as follows:

Places.	Lat.	Year.	Therm.
Pennsylvania	40° 0'	1732	5°
Paris	48 50	1709 & 1710	8
Leyden	52 8½	1729	5
Utrecht	52 5	—	4
London	51 31	1709 & 1710	0
Copenhagen	55 41½	1709	0
Upsal	59 51½	1732	-1
Petersburg	59 56	—	-28
Torneo	65 50½	1736-7	-33
Hudson's Bay	52 24	1775	-37

The middle temperature of our atmosphere is about 48° being nearly a medium of all the seasons. The French make it somewhat higher; reckoning it equal to the cave of their national observatory, or 53°. In cold countries, the air is found agreeable enough to the inhabitants while it is between 40 and 50°. In our climate we are best pleased with the heat of the air from 50 to 60°; while in the hot countries the air is generally at a medium about 70°. With us, the air is not reckoned warm till it arrives at about 64°, and it is very warm and sultry at 80°. It is to be noted, that the foregoing observations are to be understood of the state of the air in the shade; for as to the heat of bodies acted upon by the direct rays of the sun it is much greater: thus, Dr. Martine found dry earth heated to above 120°; but Dr. Hales found a very hot sun-shine heat in 1727 to be about 140°; and Musschenbroeck once observed it so high as 150; but at Montpellier the sun was so very hot, on one day in 1705, as to raise M. Amontons's thermometer to the mark of boiling water itself, which is 212°. The diversity in the heat of different climes and seasons arises from the different angles under which the sun's rays strike upon the surface of the earth. In the Phil. Trans. Abr. vol. 2. p. 165, Dr. Halley has given a computation of this heat, on the principle, that the simple action of the sun's rays, like other impulses or strokes, is more or less

less forcible, according to the sines of the angles of incidence, or to the sines of the sun's altitudes, at different times or places. Hence it follows, that, the time of continuance, or the sun's shining on any place, being taken for a basis, and the sines of the sun's altitudes perpendicularly erected upon it, and a curve-line drawn through the extremities of those perpendiculars, the area thus comprehended will be proportional to the collection of all the heat of the sun's beams in that space of time. Hence it likewise follows, that, at the pole, the collection of all the heat of a tropical day, is proportional to the rectangle or product of the sine of $23\frac{1}{2}$ degrees in 24 hours, or the circumference of a circle, or as $\frac{1}{2}$ into 12 hours, the sine of $23\frac{1}{2}$ degrees being nearly $\frac{1}{2}$ of radius. Or the polar heat will be equal to that of the sun continuing 12 hours above the horizon at 53 degrees height: and the sun is not five hours more elevated than this under the equinoctial. But as it is the nature of heat to remain in the subject, after the luminary is removed, and particularly in the air, under the equinoctial the 12 hours absence of the sun abates but little from the effect of his heat in the day; but under the pole the long absence of the sun for six months has so chilled the air, that it is in a manner frozen; and after the sun has risen upon the pole again, it is long before his beams can make any impression, being obstructed by thick clouds and fogs. From the foregoing principle Dr. Halley computes the following table, exhibiting the heat to every 10th degree of latitude, for the equinoctial and tropical sun, and from which an estimate may easily be made for the intermediate degrees.

Lat.	Sign that the sun is in.		
	γ or Δ	Θ	Ψ
0	20000	18341	18341
10	19696	20290	15834
20	18794	21737	13166
30	17321	22651	10124
40	15321	23048	6944
50	12855	22991	3798
60	10000	22773	1075
70	6840	23543	0
80	3473	24673	0
90	0	25055	0

From the same principles, and table, also he deduced the following corollaries, viz. 1. That the equatoreal heat, when the sun becomes vertical, is as twice the square of the radius. 2. That, at the equator, the heat is as the sine of the sun's declination. 3. That, in the frigid zones, when the sun sets not, the heat is as the circumference of a circle into the sine of the altitude at 6: and consequently that, in the same latitude, these aggregates of heat are as the sines of the sun's declination; and at the same declination of the sun, they are as the sines of the latitudes; and generally they are as the sines of the latitudes into the sines of declination. 4. That the equatoreal day's heat is everywhere the same as the cosine of the latitude. 5. In all places where the sun sets, the difference between the summer and winter heats, when the declinations are contrary, is equal to a circle into the sine of the altitude at 6, in the summer-parallel; and consequently those differences are as the rectangles of the sines of the latitude and declination. 6. The tropical sun has the least force of any at the equator; and at the pole it is greatest of all. Against this theory some object, that the effect of the sun's heat is not in the simple, but in the duplicate ratio of the sines of the angles of incidence; like the law of the impulse of fluids. And indeed, the quantity of the sun's direct rays received at any place, being evidently as the sine of the angle of incidence, or of the sun's altitude, if the heat be also proportional to the force with which a ray strikes, like a mechanical action or impulse of any body, then it will follow that the heat must be in the compound ratio of both, that is, as the square of the sine of the sun's altitude. But this last principle is here only assumed gratis, as we do not know a priori that the heat is proportional to the force of a striking body; and it is only experiment that can determine this point. It is certain, that heat communicated by the sun to bodies on the earth depends also much upon other circumstances beside the direct force of his rays. These must be modified by our atmosphere, and variously reflected and combined by the action of the earth's surface itself, to produce any remarkable effects

of heat. So that if it were not for these additional circumstances, it is probable, the naked heat of the sun would not be very sensible. Dr. Halley himself allowed, that many other circumstances, besides the direct force of the sun's rays, contributed to augment or diminish the effect of this, and the heat resulting from it, in different climates. No calculation, therefore, formed on the preceding theory, can be supposed to correspond exactly with observation and experiment. It has also been objected, that, according to the foregoing theory, the greatest heat in the same place should be at the summer-solstice, and the most extreme cold at the winter-solstice; which is contrary to experience. To this objection it may be replied, that heat is not produced in bodies by the sun instantaneously, nor do the effects of his heat cease immediately when his rays are withdrawn; and therefore those parts which are once heated, retain the heat for some time; which, with the additional heat daily imparted, makes it continue to increase, though the sun declines from us: and this is the reason why July is hotter than June, although the sun has withdrawn from the summer-tropic; as we also find it is generally hotter at 1, 2, or 3, P. M. when the sun has declined towards the west, than at noon, when he is on the meridian. As long as the heating particles, which are constantly received, are more numerous than those which fly away or lose their force, the heat of bodies must continually increase. So, after the sun has left the tropic, the number of particles, which heat our atmosphere and earth, constantly increases, because we receive more in the day than we lose at night, and therefore our heat must also increase. But as the days decrease, and the action of the sun becomes weaker, more particles will fly off in the night than are received in the day, by which means the earth and air will gradually cool. Farther, those places which are well cooled, require time to be heated again; and therefore January is mostly colder than December, although the sun has withdrawn from the winter-tropic, and begun to emit his rays more perpendicularly upon us. But the chief cause of the difference between the heat of summer and winter is, that in summer the rays fall more perpendicularly, and pass through a less dense part of the atmosphere; and therefore with greater force, or at least in greater number in the same place; and besides, by their long continuance, a much greater degree of heat is imparted by day than can fly off by night. For the calculations and opinions of several other philosophers on this head, see Keill's Astron. lect. 8; Ferguson's Astron. ch. 10; Long's Astron. 777; Acad. Scienc. 1719.

HEATH, in botany. See ERICA.

HEATH, BERRY-BEARING. See EMPETRUM.

HEATH, MOUNTAIN. See SAXIFRAGA.

HEATHENS. See PAGANS.

HEAVING, in the sea-language, signifies throwing any thing over-board. Also turning about the capstan, is called heaving at the capstan. Likewise, when a ship being at anchor rises and falls by the force of the waves, she is said to heave and set.

HEAVE THE LOG, See LOG, and NAVIGATION.

HEAVEN, [*heofon*, which seems to be derived from *heofd*, the places over the head, Saxon.] Among Christian divines and philosophers, is considered as a place in some remote part of infinite space, in which the omnipresent Deity affords a nearer and more immediate view of himself, and a more sensible manifestation of his glory, than in the other parts of the universe. This is often called the empyrean heaven, from that splendor with which it is supposed to be invested; and of this place the inspired writers give us the most noble and magnificent descriptions.

HEAVEN, among Pagans, was considered as the residence only of the celestial gods, into which mortals were not admitted after death, unless they were deified. As for the souls of good men, they were consigned to the Elysian fields. See ELYSIUM.

HEAVEN, in astronomy called also aethereal and starry heaven, is that immense region wherein the stars, planets, and comets, are disposed. See ASTRONOMY. This is what Moses calls the firmament, speaking of it as the work of the second day's creation; at least it is thus the word *רקיע* is usually rendered by his interpreters; though somewhat abusively, to countenance their own notion of the heavens being firm or solid. But the word properly signifies no more than expanse or extension; a term very well adapted by the prophet to the impression which the heavens make on our senses; whence, in other parts of scripture, the heaven is compared to a curtain, or a tent stretched out to dwell in. The LXX.

first added to this idea of expansion that of firm or solid; rendering it by *ερεβωλας*, according to the philosophy of those times; in which they have been very injudiciously followed by the modern translators. Des Cartes, Kircher, &c. demonstrated this heaven not to be solid, but fluid; but they still supposed it full, or perfectly dense, without any vacuity, and cantoned out into many vortices. But others have overturned not only the solidity, but the supposed plenitude, of the heavens. Sir Isaac Newton has abundantly shewn the heavens void of almost all resistance, and, consequently, of almost all matter: this he proves from the phenomena of the celestial bodies; from the planets persisting in their motions without any sensible diminution of their velocity; and the comets freely passing in all directions towards all parts of the heavens. Heaven, taken in a general sense, for the whole expanse between our earth and the remotest regions of the fixed stars, may be divided into two very unequal parts, according to the matter found therein; viz. the atmosphere, or aerial heaven, possessed by air; and the æthereal heaven, possessed by a thin, unresisting medium, called æther.

HEAVEN is also used, in astronomy, for an orb, or circular region, of the æthereal heaven. The ancient astronomers supposed as many different heavens as they observed motions therein. These they supposed all to be solid, as thinking they could not otherwise sustain the bodies fixed in them; and spherical, that being the most proper form for motion. Thus they had seven heavens for the seven planets; viz. the heavens of the moon, Mercury, Venus, the Sun, Mars, Jupiter, and Saturn. The 8th was for the fixed stars, which they called the firmament. Ptolemy adds a 9th heaven, which he called the primum mobile. Two crystalline heavens were added by king Alphonsus X. &c. to account for some irregularities in the motions of the other heavens: and lastly, an empyrean heaven was drawn over the whole, for the residence of the Deity; which made the number twelve. But others admitted many more heavens according as their different views and hypotheses required. Eudoxus supposed 23, Calippus 30, Regiomontanus 33, Aristotle 47, and Fracastor no less than 70. The astronomers, however, did not much concern themselves whether the heavens they thus allowed of were real or not; provided they served a purpose in accounting for any of the celestial motions, and agreed with the phenomena.

HEBDOMAD, [*hebdomas*, Latin,] a work; a space of seven days.

HEBDOMADARY, HEBDOMADARIUS, or HEBDOMADIUS, [from *εβδομας*, Gr. seven,] a member of a chapter or convent, whose week it is to officiate in the choir, to rehearse the anthems and prayers, and to perform the usual functions which the superiors perform at solemn feasts, and other extraordinary occasions.

HEBDOMAGENES, [from *επτα*, seven, and *γεννησις*, birth,] a title of Apollo, so named from his being born on the 7th day of the month; whence the 7th days were held sacred to him. See **HEBDEME**.

HEBDOMARIUS, or HEBDOMARY. See the article **HEBDOMADARY**.

HEBDOME, [*εβδομας*, Gr. the seventh day,] a solemnity of the ancient Greeks, in honour of Apollo, in which the Athenians sung hymns to his praise, and carried in their hands branches of laurel. It was observed on the seventh day of every lunar month.

HEBE, in ancient mythology, a goddess, the idea of whom, among the Romans, seems to have been that of eternal youth, or immortality of bliss. She is fabled to have been a daughter of Jupiter and Juno. According to some she was the daughter of Juno only, who conceived her after eating lettuce. She was fair, and always in the bloom of youth, being the goddess of youth, and made by her mother cup-bearer to the gods.

HEBENSTRETIA, in botany, a genus of the angiospermia order and didynamia class of plants; natural order, Aggregata. Calyx emarginated, divided below; corolla unilabiate; the lip rising upwards, and quadrifid; capsule dispermonous; stamina inserted into the margin of the limb of the corolla. It has six species, natives of the Cape.

HEBREW LANGUAGE, ANCIENT, is the language spoken by the ancient Hebrews, and wherein the Old Testament is written. This appears to be the most ancient of all the lan-

guages in the world, at least we know of none older; and some learned men are of opinion, that this is the language in which God spoke to Adam in Paradise. Dr. Sharpe adopts the opinion, that the Hebrew was the original language; not indeed that the Hebrew is the unvaried language of our first parents, but that it was the general language of men at the dispersion; and however it might have been improved and altered from the first speech of our first parents, it was the original of all the languages, or almost all the languages, and dialects, that have since arisen in the world. See **PHILOLOGY**. The books of the Old Testament are the only pieces to be found, in all antiquity, written in pure Hebrew; and the language of many of these is extremely sublime: it appears perfectly regular, and particularly so in its conjugations. Indeed, properly speaking, it has but one conjugation; but this is varied in each seven or eight different ways, which has the effect of so many different conjugations, and affords a great variety of expressions, to represent by a single word, the different modifications of a verb, and many ideas, which in the modern, and in many of the ancient and learned languages, cannot be expressed without a periphrasis. The primitive words, which are called roots, have seldom more than three letters or two syllables. In this language there are 22 letters, five of which are vowels, viz. *Aleph*, *He*, *Jod*, *Ain* or *Oin*, and *Vau*, answering to our *a*, *e*, *i*, *o*, and *u*; but then each vowel is divided into two, a long and a short, the sound of the former being somewhat grave and long, and that of the latter short and acute. And the two last vowels have sounds that differ in other respects, besides quantity and a greater or less elevation. To those 10 or 12 vowels may be added others, called semi-vowels, which connect the consonants, and make the easier transitions from one to another. The number of accents in this language is indeed prodigious: of these there are near 40, the use of some of which, notwithstanding all the inquiries of the learned, are not yet perfectly known. We know, in general, that they serve to distinguish the sentences, like the points called commas, semicolons, &c. in our language; to determine the quantity of the syllables; and to mark the tone with which they are to be spoken or sung. It is no wonder, then, that there are more accents in the Hebrew than in other languages, since they perform the office of three different things, which in other languages are called by different names. As we have no Hebrew but what is contained in the Scripture, that language to us wants many words; not only because, in those primitive times, the languages were not so copious as at present; but also on this account, that the inspired writers had no occasion to mention many of the terms that might be in the language. The Chaldee, Syriac, Ethiopic, &c. languages, are by some held to be only dialects of the Hebrew; as the French, Italian, Spanish, &c. are dialects of the Latin. It has been supposed by many very learned men, that the Hebrew letters were often used hieroglyphically, and that each had its several distinct sense understood as a hieroglyphic. Neuman, who seems to have taken vast pains to find out this secret meaning of these letters, gives the following explication: *aleph*, he says, is a character denoting motion, readiness, and activity; *beth* signifies, 1. Matter, body, substance, thing; 2. Place, space, or capacity; and, 3. In, within, or contained: *gimel* stands for flexion, bending or obliquity of any kind: *daleth* signifies any protrusion made from without, or any protrusion of any kind: *he* stands for presence, or demonstrative essence of any thing: *vau* stands for copulation or growing together of things: *daain* expresses vehement protrusion and violent compression, such as is occasioned by at once violently discharging and constringing a thing together; it also signifies sometimes the straitening of any figure into a narrow point at the end: *cheth* expresses association, society, or any kind of composition or combination of things together: *teth* stands for the withdrawing, drawing back, or recess, of any thing: *jod* signifies extension and length, whether in matter or in time: *caph* expresses a turning, curvedness, or concavity: *lamed* stands for an addition, access, impulse, or adversation, and sometimes for pressure: *mem* expresses amplitude, or the amplifying of any thing in whatever sense; in regard to continue qualities, it signifies the adding of length, breadth, and circumference; and in distinct qualities it signifies multitude: *nun* signifies the propagation of one thing from another, or of the same thing from one person to another: *samech* expresses cincture and coarctation: *guain* stands for observation, objection, or obviation: *pe* stands for a crookedness or an angle of

of any figure: **tsade** expresses contiguity and close succession: **koph** expresses a circuit or ambit: **resh** expresses the egress of any thing, as also the exterior part of a thing, and the extremity or end of any thing: **shin** signifies the number three, or the third degree, or the utmost perfection of any thing: **tau** expresses a sequel, continuation, succession, of any thing. According to this explication, as the several particular letters of the Hebrew alphabet separately signify the ideas of motion, matter, space, and several modifications of matter, space, and motion, it follows, that a language, the words of which are composed of such expressive characters, must necessarily be of all languages the most perfect and expressive, as the words formed of such letters, according to their determinate separate signification, must convey the idea of all the matters contained in the sense of the several characters, and be at once a name and a definition, or succinct description of the subject, and all things material as well as spiritual, all objects in the natural and moral world, must be known as soon as their names are known, and their separate letters considered. Urim and Thummim are thus easily explained, and found, perhaps the most apposite and expressive words that were ever formed. See that article.

HEBREW LANGUAGE, RABBINICAL, or the MODERN HEBREW, is the language used by the rabbins in their writings. The basis or body hereof is the Hebrew and Chaldee, with divers alterations in the words of these two languages, the meanings whereof they have considerably enlarged and extended. Abundance of things they have borrowed from the Arabic: the rest is chiefly composed of words and expressions from the Greek; some from the Latin: and others from the other modern tongues; particularly that spoken in the place where each rabbin lived or wrote. The rabbinical Hebrew must be allowed to be a very copious language. M. Simon, in his Hist. Crit. du Vieux Testam. liv. iii. ch. 27, observes, that there is scarce any art or science but the rabbins have treated thereof in it. They have translated most of the ancient philosophers, mathematicians, astronomers, and physicians; and have written themselves on most subjects: they do not want even orators and poets. This language, notwithstanding it is so crowded with foreign words, has many beauties in the works of those who have written well in it.

HEBREW BIBLE. See BIBLE.

HEBREWS, or EPISTLE TO THE HEBREWS, a canonical book of the New Testament. Though St. Paul did not prefix his name to this epistle, the concurrent testimony of the best authors, ancient and modern, afford such evidence of his being the author of it, that the objections to the contrary are of little or no weight. His mentioning himself in it, as lately a prisoner in Italy, and his promise to visit the Hebrews, together with Timothy, who had been released from imprisonment, both denote the writer, and the time of his writing this epistle, that it was just after the deliverance of St. Paul from his first trial at Rome. The Hebrews, to whom this epistle was written, were the believing Jews of Palestine, and its design was to convince them, and, by their means, all the Jewish converts, wheresoever dispersed, of the insufficiency and abolishment of the ceremonial and ritual law. In order to which he undertakes to shew, first, the superior excellency of Christ's person above that of Moses: secondly, the superiority of Christ's priesthood above the Levitical: thirdly, the mere figurative nature, and utter insufficiency of the legal ceremonies and sacrifices: and, fourthly, that to forsake the Mosaic law, was not, as the Jews boldly asserted, to apostatize from God, but was their indispensable duty and obligation. These particulars are intermixed with proper inferences and exhortations, all tending to shew the Jewish Christians the unreasonableness, folly, and danger, of relapsing into Judaism.

HEBRIDES, ÆBUDÆ, or WESTERN ISLANDS, the general name of some islands, lying to the N. W. of Scotland, of which kingdom they constitute a part. They are situated between 55° and 59° lat. N. are supposed to be about 300 in number, and to contain 48,000 inhabitants. The principal are Skye, Mull, Ilay, Arran, St. Kilda, N. and S. Uist, Cannay, Staffa, Jura, Lewis, and Harris. See these articles.

HEBRIDES, New, a cluster of islands in the Pacific Ocean, so named by Captain Cook, who explored the whole cluster, and, besides ascertaining the extent and situation of these islands, added the knowledge of several others. They extend 375 miles, from N. N. W. to S. S. E. The natives are civil and hospitable; of a

slender make, and dark colour, and have mostly frizzled hair. The productions are cocoa-nuts, bread-fruit, plantains, sugar-canes, yams, &c. The whole cluster consists of the following islands; some of which have received names from the different European navigators, others retain the names which they bear among the natives: viz. Tierra del Espiritu Santo, Mallicollo, St. Bartholomew, Isle of Lepers, Aurora, Whitsuntide, Ambrym, Immer, Apce, Three Hills, Sandwich, Montagu, Hinchinbrook, Shepherd, Erromanga, Erromon, Anaton, and Tanna. They are situated between 160° 40' and 170° 21' Lon. E. and between 14° 25' and 20° 4' Lat. S.

HEBRON, in ancient geography, a city seated in the hilly country of the tribe of Judah to the south. Its more ancient name was Kirjath-Arba, or Cariath-Arba. In antiquity it vied with the more ancient cities of Egypt, being seven years prior to Zoan, translated Tanis by the LXX. Josephus makes it not only older than Tanis, but even than Memphis. Hebron is twenty-one miles S. of Bethlehem, and twenty-four S. W. of Jerusalem.

HEBRUS, in ancient geography, the largest river of Thrace, which rises from mount Scombrus, and falls by two mouths into the Ægean Sea.

HEBUDÆ, HEBUDES, or ÆBUDÆ, in ancient geography, islands on the W. of Scotland, now called the Western Isles, and Hebrides.

HECATEA, [*Ἑκάτα*], in antiquity, statues erected to the goddess Hecate, who, the Athenians believed, was the overseer of their families, and the protectress of their children.

HECATE, in the mythology, a name of Diana. She was called Luna in heaven, Diana on earth, and Hecate or Proserpine in hell; whence her name of Diva Triformis, Tergemina, Triceps. She was supposed to preside over enchantments. She was generally represented like a woman, with the head of a horse, a dog, or a boar; and sometimes she appeared with three different bodies, and three faces, with one neck.

HECATE, in fabulous history, a queen of Taurica Chersonesus, daughter of Peres and Asteria, who poisoned her father.

HECATESIA, [*Ἑκατεσία*], in antiquity, an annual solemnity observed by the Stratonicensians, in honour of Hecate.

HECATOMB, in antiquity, was a sacrifice of 100 beasts of the same kind, at 100 altars, and by 100 priests or sacrificers. The Greek word, *ἑκατόμῃ*, properly signifies a magnificent sacrifice. Others derive it from the Greek *ἑκατόν*, a hundred, and *βῆς*, a bullock; others from *ἑκατόν* and *πῆς*, a foot; on which principle they hold, that the hecatomb might consist of only twenty-five four-footed beasts; and that it did not matter what kind of beasts were chosen for victims, provided there were but 100 feet. Pythagoras is said to have sacrificed a hecatomb to the Muses of 100 oxen, in gratitude for discovering the demonstration of the forty-seventh proposition of Euclid. Strabo relates that there were 100 cities in Laconia, and that each city used to sacrifice a bullock every year for the common safety of the country; whence the institution of hecatombs. Others refer the origin of hecatombs to a plague, wherewith the 100 cities of Peloponnesus were afflicted; for the removal whereof, they jointly contributed to do so splendid a sacrifice.

HECATOMBAEON, [*Ἑκατομβαιών*], in chronology, the first month of the Athenian year. It consisted of thirty days, and began on the first new moon after the summer-solstice; answering to the latter part of June and beginning of July. The Boeotians called it Hippodromus, and the Macedonians Loüs, (*Λοῦς*, or *Λοῦς*). See MONTH. The word is derived from the Greek *ἑκατόμῃ*, a hecatomb, because of the great number of hecatombs sacrificed in it.

HECATOMPOLIS, a surname of Crete, from its 100 cities.

HECKLE See FLAX-DRESSING, and HATCHEL.

HECLA, a volcano of Iceland, and one of the most furious in the world. See ICELAND. It was visited in 1772 by Dr. Van Troil, a Swedish gentleman, along with Mr. (now Sir Joseph) Banks, Dr. Solander, and Dr. James Lind of Edinburgh. On their first landing they found a tract of land sixty or seventy miles in extent entirely ruined by lava, which appeared to have been in the highest state of liquefaction. Having undertaken a journey to the top of the mountain, they travelled from 300 to 360 English miles over an uninterrupted tract of lava; and had at length the pleasure of being the first who had arrived at the summit of the mountain. Hecla, according to their accounts, is situated in the

S. part of the island, about four miles from the sea-coast; and is divided into three parts at the top, the middle-point being the highest. From an exact observation with Ramsden's barometer, it is 5000 feet above the level of the sea. They were obliged to quit their horses at the first opening from which the fire had burst. They describe this as a place with lofty glazed walls and high-glazed cliffs, unlike any thing which they had ever seen before. A little higher up they found a large quantity of grit and stones; and still farther on another opening, which, though not deep, descended lower than that of the highest point. Here they imagined they plainly discerned the effects of boiling water; and not far from thence the mountain was covered with snow, excepting some spots. The reason of this difference they perceived to be the hot vapour ascending from the mountain. As they ascended higher they found the spots become larger: and about 200 yards below the summit, a hole about a yard and an half in diameter was observed, from whence issued so hot a steam, that they could not measure the degree of heat with the thermometer. The mountain seems to be made up, not of lava, but of sand, grit, and ashes; which are thrown up with the stones partly discoloured, and partly melted by the fire. Several sorts of pumice-stones were found on it, among which was one with some sulphur. Sometimes the pumice was so much burnt, that it was as light as tow. Its form and colour were sometimes very fine, but at the same time so soft, that it was difficult to remove it from one place to another. The common lava was found in both large and small pieces; as well as a quantity of black jasper burned at the extremities, and resembling trees and branches.

HECTIC-FEVER. See **MEDICINE.**

HECTOR, the son of Priam and Hecuba, and the father of Astyanax, celebrated for the valour with which he defended the city of Troy against the Greeks. He was killed by Achilles, who dragged his body, fastened to his chariot, thrice round the walls of Troy, and afterwards restored it to Priam for a large ransom.

HECUBA, in fabulous history, the wife of Priam, the last king of Troy, and the mother of nineteen of his fifty-three children. She was the daughter of Dymas, according to Homer, or of Cisseus, according to Virgil. When with child of Paris she dreamed that she brought forth a firebrand.

HE DAMORA, a town of Sweden, in Westmania, on the Dahl, fifty-five miles N.W. of Upsal. Lon. 17. 7. E. Lat. 60. 14. N.

HERERA, *IVY*; in botany, a genus of the monogynia order, and pentandria class of plants; natural order, *Hederaceæ*. Petals five, oblong; berry pentaspermous, girt by the calyx. There are six species.

HERERACEÆ, [from *hedera*, ivy,] the forty-sixth order in Linnæus's fragments of a natural method. See **BOTANY.**

HEDGE, [*hegge*, Sax.] in agriculture, a fence made round grounds with prickly bushes, or woven twigs. Hedges are either planted to make fences round inclosures, or to divide the several parts of a garden. When they are designed as outward fences, they are planted either with hawthorn, crabs, or black-thorn: but those hedges which are planted in gardens, either to surround wilderness-quarters, or to screen the other parts of a garden from sight, are planted according to the fancy of the owner. Some prefer evergreens, in which case the holly is best; next the yew, then the laurel, laurustinus, phyllyrea, &c. Others prefer the beech, the horn-beam, and the elm. Before planting, it is proper to consider the nature of the land, what sort of plants will thrive best in it; and what is the soil from whence they are to be taken. The sets ought to be about the thickness of one's little finger, and cut within about four or five inches of the ground; they ought to be fresh taken up, straight, smooth, and well-rooted. Those plants that are raised in the nursery are to be preferred. In planting outside-hedges, the turf is to be laid, with the grassy side downwards, on that side of the ditch on which the bank is designed to be made; and some of the best mould should be laid upon it to bed the quick, which is set upon it at a foot asunder. When the first row of hawthorn, or quick is set, it must be covered with mould; and when the bank is a foot high, another row of sets may be laid against the spaces of the former, and covered like the others. The bank is then to be topped with the bottom of the ditch, and a dry or dead hedge laid, to shade and defend the under plantation. Stakes should then be driven into the loose earth, so low as to

reach the firm ground: these are to be placed at about two feet and a half distant: to render the edge yet stronger, edder it, that is, bind the top of the stakes with small long poles, and when the eddering is finished, drive the stakes anew. The quick must be kept constantly weeded, and secured from being cropped by cattle; and in February it will be proper to cut it within an inch of the ground, which will cause it to strike root afresh, and help it much in the growth. The crab is frequently planted for edges. Plants raised from the kernels of the small wild-crabs are to be preferred to those raised from the kernels of all sorts of apples without distinction; because the plants of the true small crab never shoot so strong as those of the apples, and may therefore be better kept within the proper compass of a hedge. The black-thorn, or sloe, is often planted for hedges. The best method is, to raise the plants from the stones of the fruit, which should be sown about the middle of January, if the weather permit, in the place where the hedge is intended. When they are kept longer out of the ground, it will be proper to mix them with sand, and keep them in a cool place. The same fence will do for it when sown, as when planted. The holly is sometimes planted for hedges; but where it is exposed, it is very difficult to prevent its being destroyed: otherwise, it is by far the most beautiful plant; and, being an evergreen, affords much better shelter for cattle in winter than any other sort of hedge. See **HUSBANDRY.**

HEDGE-PUMITORY. See **FUMARIA.**

HEDGE-ROG. See **ERINACEUS.**

HEDGE-HYSSOP. See **GRATIOLA.**

HEDGE-MUSTARD. See **ERVISMUM.**

HEDGE-SPARROW. See **MOTACILLA.**

HEDJAS, or **HEDSJAS**, a province of Arabia, bounded on the E. by Nejed; on the S. by Yemen; on the W. by the Arabian Gulph; and on the N. by the desert of Sinai.

HEDWIGIA, a genus of the octandria monogynia class and order. Calyx four-toothed; corolla four-cleft; style none; capsule trilocular; seed a nut. There is one species, a tree of St. Domingo.

HEDYCARYA, a genus of the icosandria order, and diœcia class of plants. Calyx of the male cleft in eight or ten parts; no corolla; antheræ in the bottom of the calyx, four-furrowed, bearded at top. Calyx and corolla of the female as in the male; germs pedicellate; the nuts pedicellate and monospermous. There is one species, a tree of Guiana.

HEDYCREA, a genus of the class and order pentandria monogynia. Calyx one-leaved, hemispherical, five-toothed; corolla none; drupe oval, one-celled; nectary ovate, covered with filices; one-celled; shell hard. There is one species, a tree of Guiana.

HEDYOSMUM, a genus of the class and order monœcia polyandria. The male is an ament with anthers: no corolla, perianth, or filaments; female calyx three-toothed; corolla none; style one, three-cornered; berry three-cornered, one-seeded. There are two species, shrubs of Jamaica.

HEDYOTIS, a genus of the monogynia order, and tetrandria class of plants; natural order, *Stellatæ*. Corolla monopetalous, funnel-shaped; capsule bilocular, polyspermous, inferior. There are eight species, herbs of Ceylon, &c.

HEDYPTIS, a genus of the class and order syngenesia polygamia æqualis. The calyx calyced, with short scales; seeds crowned with the calyces; receptacle naked, hollow-dotted.

HEDYSARUM, **FRENCH HONEY-SUCKLE**; in botany, a genus of the decandria order, and diadelphia class of plants; natural order, *Papilionacæ*. The carina of the corolla is transversely obtuse: the seed-vessel a legumen with monospermous joints. There are ninety species, see **PLATE LXV.**

HEEL. See **ANATOMY.**

HEEL, in the sea-language. If a ship leans on one side, whether she be aground or afloat, then it is said she heels a-starboard or a-port; or that she heels offwards, or to the shore; that is, inclines more to one side than to another.

HEEL OF A HORSE, the lower hinder part of the foot comprehended between the quarters, and opposite to the toe. The heel of a horse should be high and large, and one side of it should not rise higher than the other upon the pastern. See **FARRIERY.**

HEEL OF A HORSEMAN. This being the part that is armed with the spur, the word is used for the spur itself; "This horse understands the heel well." To ride a horse from one heel to another,

other, is to make him go sideways, sometimes to one heel and sometimes to another.

HEGIRA, [formed of *הגירה*, *hagirah*, flight; of *הגר*, to fly,] in chronology, a celebrated epocha among Mohammedans. The event which gave rise to this epocha was the flight of Mohammed from Mecca, with his new proselytes, to avoid the persecution of the Coraischites; who, being then most powerful in the city, could not bear that Mohammed should abolish idolatry, and establish his new religion. This flight happened in the fourteenth year after Mohammed had commenced prophet: he retired to Medina, which he made the place of his residence. To render this epocha more creditable, the Mohammedans affect to use the word *hegira* in a peculiar sense for an act of religion, whereby a man forsakes his country, and gives way to the violence of persecutors and enemies of the faith: they add, that the Coraischites, being then the strongest party in the city, obliged their prophet to fly, as not being able to endure his abolishing of idolatry. This flight was not the first of Mohammed's, but it was the most famous. It happened in the fourteenth year from his assuming the character of prophet and apostle, and promulgating his new religion. The orientals do not agree with us as to the time of the *hegira*. Among the Mohammedans, Amasi fixes it to A. D. 630, and from the death of Moses 2347; and Ben Casseni to A. M. 5804: according to the Greek computation among the Christians, Said Ebn Batrik refers the *hegira* to A. D. 614, and A. M. 6113. Khondemir relates, that it was Omar, the second caliph, that first established the *hegira* as an epocha, and appointed the years to be numbered from it: at the time he made this decree, there were already seven years elapsed. This establishment was made in imitation of the Christians, who, in those times, reckoned their years from the persecution of Dioclesian. But there is another *hegira*, and that earlier too, though of less eminence. Mohammed, in the fourteenth year of his mission, was obliged to relinquish Medina: the Coraischites had all along opposed him very vigorously, as an innovator and disturber of the public peace; and many of his disciples, not enduring to be reputed followers of an impostor, desired leave of him to abandon the city, for fear of being obliged to renounce their religion. This retreat makes the first *hegira*. These two *hegiras* the Mohammedans, in their language, call *hegira-taa*. The years of the *hegira* consist only of 354 days. To reduce these years to the Julian calendar, *i. e.* to find what Julian year a given year of the *hegira* answers to, reduce the year of the *hegira* given into days, by multiplying by 354, divide the product by 365, and from the quotient subtract the intercalations, *i. e.* as many days as there are four years in the quotient; and lastly, to the remainder add 622. For a table of the years of the *hegira* connected with the years of the Christian era, see the article **EPOCH**.

HEIDEGGER, JOHN HENRY, professor of divinity at Zurich, was born in 1633. He published, 1. *Exercitationes Selectæ de Historia sacra Patriarcharum*, 2 vols. 4to. 2. *De Ratione Studiorum Opuscula Aurea*, 12mo. 3. *Tumulus Tridentini Concilii*, 4to. 4. *Historia Papatus*, 4to.

HEIDELBERG, a populous town of Germany, capital of the Lower Palatinate, with a celebrated university. It is noted for its great tun, which holds 800 hogsheads, generally kept full of good Rhenish wine. The town stands on the Neckar, forty-four miles S. S. E. of Mentz.

HEIDENHEIM, a town of Germany, in Suabia. Lon. 10. 19. E. Lat. 48. 37. N.

HEIGHTS, METHODS OF MEASURING. See **BAROMETER**, **MENSURATION**, and **TRIGONOMETRY**.

HEILA, a town of Royal Prussia, in Cassubia, twelve miles N. of Dantzic.

HEILBRONN, an imperial town of Germany, in Suabia, twenty miles N. of Stuttgart, and twenty-six E. of Heidelberg.

HEILEGEN HAVE, a sea-port town of Germany, in Lower Saxony, on the Baltic. Lon. 11. 15. E. Lat. 57. 30. N.

HEILGELAND, an island in the North Sea, belonging to Denmark, nine miles in circumference, with a light-house; thirty-three miles N. W. of the mouth of the Elbe. Lon. 7. 57. E. Lat. 54. 22. N.

HEINECCIUS, JOHN GOTTLIEB, one of the greatest civilians of the eighteenth century, born at Eisenberg, in Altenberg, in 1681. After having studied at Gossar and Leipsic, he became professor of philosophy at Hall in 1710; and in 1721, he was

made professor of civil law, with the title of Counsellor of the Court. His great reputation made the states of Friesland invite him to Franeker in 1724; but in 1727, the king of Prussia prevailed on him to accept of a professorship of law at Frankfort on the Oder, where he distinguished himself till 1733. Becoming again professor at Hall, he remained there till his death, in 1741, though invited to Marburg, Denmark, and Holland. He wrote many works, all of them much esteemed. The principal are, 1. *Antiquitatum Romanarum Jurisprudentiam Illustrantium Syntagma*. This excellent abridgement gave rise to his reputation in foreign countries. 2. *Elementa Juris Civilis*. 3. *Fundamenta Styli Cætoris*; a most useful work for forming a Latin style. 4. *Elementa Philosophiæ Rationalis et Moralis*. 5. *Historia Juris Civilis Romanæ ac Germanicæ*. 6. *Elementa Juris Naturæ et Gentium*, &c.

HEINECKEN, or **HEINETKEN**, CHRISTIAN, an extraordinary child, the prodigy of the North, born at Lubeck in 1721. He spoke his maternal tongue fluently at ten months. At one year old, he knew the principal events of the Pentateuch; in two months more, he was master of the entire history of the Old and New Testaments; at two years and an half, he answered the principal questions in geography, and in ancient and modern history; and he spoke Latin and French with great facility before his fourth year. His constitution was so delicate, that he was not weaned till a few months before his death. M. Martini of Lubeck published a pamphlet in 1730, in which he endeavoured to give natural reasons for the extraordinary capacity of this child, who died in his fifth year.

HEIR, [*heres*, Lat.] in law, signifies the person who succeeds another by descent to lands, tenements, and hereditaments, being an estate of inheritance, or an estate in fee; because nothing passes by right of inheritance but in fee. See **CONSANGUINITY**, **DESCENT**, **INHERITANCE**, **SUCCESSION**, and **LAW**. If land be given to a man for ever, or to him and his assigns for ever, this vests in him but an estate for life. This very great nicety about the insertion of the word *heirs* in all feoffments and grants, in order to vest a fee, is plainly a relic of the feudal strictness, by which it was required, that the form of the donation should be punctually pursued; or that, as Craig expresses it, in the words of Baldus, "*donationes sint stricti juris, ne quis plus, donasse præsumatur quam in donatione expresserit*." And therefore, as the personal abilities of the donee were originally supposed to be the only inducements to the gift, the donee's estate in the land extended only to his own person, and subsisted no longer than his life; unless the donor, by an express provision in the grant, gave it a longer continuance, and extended it also to his heirs. But this rule is now softened by many exceptions. For, 1. It does not tend to devise by will; in which, as they were introduced at the time when the feudal rigour was apace wearing out, a more liberal construction is allowed: and therefore by a devise to a man for ever, or to one and his assigns for ever, or to one in fee-simple, the devisee hath an estate of inheritance; for the intention of the deviser is sufficiently plain from the words of perpetuity annexed, though he hath omitted the legal words of inheritance. But if the devise be to a man and his assigns, without annexing words of perpetuity, there the devisee shall take only an estate for life; for it does not appear that the deviser intended any more. 2. Neither does this rule extend to fines or recoveries, considered as a species of conveyance; for thereby an estate in fee passes by act and operation of law without the word *heirs*; as it does also, for particular reasons, by certain other methods of conveyance, which have relation to a former grant or estate, wherein the word *heirs* was expressed. 3. In creations of nobility by writ, the peer so created hath an inheritance in his title, without expressing the word *heirs*; for they are implied in the creation, unless it be otherwise specially provided; but in creations by patent, which are stricti juris, the word *heirs* must be inserted, otherwise there is no inheritance. 4. In grants of lands to sole corporations and their successors, the word successors supplies the place of heirs; for as heirs take from the ancestor, so doth the successor from the predecessor. Nay, in a grant to a bishop, or other sole spiritual corporation, in frank almoign, the word frank almoign supplies the place of successors (as the word successors supplies the place of heirs), *ex vi termini*; and in all these cases a fee simple vests in such sole corporation. But, in a grant of lands to a corporation aggregate, the word successors is not necessary,

cessary, though usually inserted; for albeit such simple grant be strictly only an estate for life, yet as that corporation never dies, such estate for life is perpetual, or equivalent to a fee simple, and therefore the law allows it to be one. Lastly, in the case of the king, a fee simple will vest in him, without the word heirs or successors in the grant; partly from prerogative royal, and partly from a reason similar to the last, because the king, in judgement of the law, never dies. But the general rule is, that the word heirs is necessary to create an estate of inheritance.

HEIR APPARENT, is a person so called in the lifetime of his ancestors, at whose death he is heir at law.

HEIR PRESUMPTIVE is one who, if the ancestor should die immediately, would, in the present circumstance of things, be his heir; but whose right of inheritance may be defeated by the contingency of some nearer heir being born.

HEIRESS, is a female heir to a person having an estate of inheritance of lands. If there are more than one, they are called co-heiresses, or rather, in legal expression, co-heirs. The offence of stealing an heiress is founded on the statute 3 Hen. VII. c. 2, which enacts, that if a man shall, for lucre, take any woman, being maid, widow, or wife, and having substance either in goods or lands, or being heir-apparent to her ancestor, contrary to her will, and afterwards she be married to such misdoer, or by his consent to another, or defiled; he, his procurers and abettors, and such as knowingly receive such women, shall be deemed principal felons; and by 39 Eliz. c. 9, the benefit of clergy is taken away from principals, procurers, and accessaries before. And it is not material whether a woman so taken contrary to her will, be at last married or defiled with her own consent or not, if she were under the force at the time.

HEIR-LOOMS, are such goods and personal chattels as, contrary to the nature of chattels, shall go by special custom to the heir, along with the inheritance, and not the executor of the last proprietor. Heir-loom comprehends divers implements; as tables, presses, cupboards, and bedsteads.

HEIRSHIP MOVEABLES, in Scotch law, the best of certain kinds of moveables, which the heir of line is intitled to take, besides the heritable estate.

HEISKER, an island of Scotland, 6 miles N. of North Uist.

HEISTERIA, in botany, a genus of the monogynia order, and decandria class of plants; natural order Holoraceæ. Calyx five cleft; petals, five; drupe having a large, coloured calyx. One species, coccinea, a native of Martinico.

HELEN, or **HELENA**, in fabulous history, the daughter of Tyndarus, or according to the poets, of Jupiter and Leda, was married to Menelaus, king of Sparta, but was stolen from him by Theseus, B. C. 1235. She was restored soon after; but carried off again by Paris, which occasioned the famous Trojan war.

HELENA, St. an island in the Atlantic Ocean, belonging to the English East India company. Its greatest length is about eight miles, and its circumference about twenty. It has some high mountains, particularly one called Diana's Peak, which is covered with woods to the very top. Some of the hills bear evident marks of a volcanic origin; and some have huge rocks of lava, and a kind of half-vitrified flags. The island is laid out entirely in gardens and pasturage. Peaches are the only European fruits that thrive here. Cabbages and other greens are devoured by caterpillars; and corn is destroyed by rats. Furze has been of singular advantage to the inhabitants of St. Helena. Before the introduction of that plant, the ground was parched by the intense heat, and all kinds of herbage were shrivelled up. But the furze-bushes, which throve as it were in spite of the sun, preserved a degree of moisture in the ground, which made the grass spring up vigorously, and the country became covered with a rich and beautiful sod. The furze is now used for fuel. The number of inhabitants does not exceed two thousand, including five hundred soldiers, and six hundred slaves. By the India ships, which they supply with refreshments, they are provided with all sorts of necessities; and the company annually order one or two of their ships to touch there in their way to India, to supply them with European goods and provisions. Many of their slaves are employed in catching fish, which are very plentiful; and, by the help of these, together with their poultry, cattle, roots, and salt provisions, they subsist very happily through the year. St. Helena was first discovered by the Portuguese in 1502, on St. Helen's day; whence its name. St. Helena lies

1200 miles W. of Africa, and 1800 E. of South America. Lon. 5. 49. W. Lat. 15. 55. S.

HELENA, St. an island of South Carolina.

HELENium, **BASTARD SUN-FLOWER**; a genus of the polygamia superflua order, and syngenesia class of plants; natural order, Compositæ. Receptacle naked in the middle; under the radius paleaceous; pappus consists of five short awns; calyx simple, multipartite; florets of the radius semitrid. The species are two, natives of America.

HELENUS, in fabulous history, a celebrated soothsayer, son of Priam and Hecuba. He was greatly respected by all the Trojans.

HELEPOLIS, in the ancient art of war, a machine for battering down the walls of a place, the invention of which is ascribed to Demetrius Poliorcetes. Diodorus Siculus says, that each side of the Helepolis was 405 cubits in breadth, and 90 in height; that it had nine stages, and was carried on four strong solid wheels, eight cubits in diameter; that it was armed with large battering rams, and had two roofs capable of supporting them; that in the lower stages there were different sorts of engines for casting stones; and in the middle they had large catapultas for discharging arrows, and smaller ones in those above, with a number of expert men for working all these machines.

HELIACAL, [*heliacque*, Fr, from *ἥλιος*,] in astronomy, is applied to the rising and setting of the stars. A star is said to rise heliacally, when after having been in conjunction with the sun, and on that account invisible, it comes to be at such a distance from him as to be seen in the morning before sun-rising; the sun by his apparent motion, receding from the star towards the east. The heliacal setting is when the sun approaches so near a star as to hide it with his beams, which prevent the fainter light of the star from being perceived; so that the terms apparition and occultation would be more proper than rising and setting.

HELIADES, in mythology, the daughters of Apollo and Clymene, who were so affected with the death of their brother Phæthon, that the gods, in compassion, transformed them into poplars on the banks of the Eridanus. Their names were Phæthusa, Lampetia, and Phœbe.

HELLEA, in Grecian antiquity, the greatest and most frequented court in Athens for the trial of civil affairs. See **HELIASTÆ**.

HELIANTHUS, the **GREAT SUNFLOWER**; a genus of the polygamia frustranea order, and syngenesia class of plants; natural order, Compositæ. Receptacle paleaceous, plane; pappus diphylous; calyx imbricated; scales standing a little out at the tops. There are twelve species, most of which are now common in our gardens, though all of them are natives of America. They are all very hardy, and prosper in almost any soil or situation. They may be propagated either by seeds, or by parting their roots.

HELIASÆ, or **HELIASTES**, in antiquity, the judges of the court Heliæa. They were so called, according to Ulpian, from *ἥλιος*, to assemble in a great number; or, according to others, from *ἥλιος*, the sun, because they held their assemblies in an open place, and from sun-rise to sun-set. They composed the most numerous and important of the Athenian tribunals. Their province was to explain obscure laws, and to give authority to those which had been violated. The Thesmothetæ convoked the assembly of the Heliastæ, which sometimes amounted to a thousand, sometimes to one thousand five hundred, judges. Mr. Blanchard is of opinion, that, to make this number, the Thesmothetæ sometimes summoned those of each tribe who had last quitted the public offices which they had exercised in another court. The assemblies of the Heliastæ were not frequent, as they would have interrupted the jurisdiction of the stated tribunals and the common course of affairs. The Thesmothetæ paid to each member of this assembly, for his attendance, three oboli. Hence Aristophanes terms them the brothers of triobolus. They were fined if they came too late, and if the orators had begun to speak, they were not admitted. They were paid out of the public treasury, and their pay was called *misthos heliasticus*. The judges were bound to the right performance of their duty by a strict and solemn oath.

HELICOID PARABOLA, or the **PARABOLIC SPIRAL**, is a curve arising from the supposition that the common or Apollonian parabola is bent or twisted, till the axis come into the periphery

riphery of a circle, the ordinates still retaining their places and perpendicular positions with respect to the circle, all these lines still remaining in the same plane. Thus the axis of a parabola being bent into the circumference BCDM (Plate XCV. fig. 13), and the ordinates CF, DG, &c. still perpendicular to it, then the parabola itself, passing through the extremities of the ordinates, is twisted into the curve BFG, &c. called the helicoid, or parabolic spiral. Hence all the ordinates CF, DG, &c. tend to the centre of the circle, being perpendicular to the circumference. Also, the equation of the curve remains the same as when it was a parabola, viz. putting x = any circular absciss BC, and y = CF, the corresponding ordinate, then is $px = y^2$, where p is the parameter of the parabola.

HELICON, in ancient geography, a mountain in the neighbourhood of Parnassus and Cytheron, sacred to Apollo and the Muses. It is situated in Livadia, and now called Zagura or Zaguya.

HELICONIA, in botany, a genus of the monogynia order, and pentandria class of plants. Spatha universal and partial; no calyx; corolla, three-petaled; nectarium, two-leaved; capsule, three-grained. It has three species, natives of the West Indies.

HELICONIAN, or **HELICONIDES**, epithets of the Muses, from Mount Helicon.

HELICTERES, the **SCREW-TREE**; a genus of the decandria order, and gynandria class of plants; natural order, Columniferae. Calyx monophyllous, oblique; petals, five; nectarium consists of five petal-like leaflets; capsules intorted or twisted inwards. There are nine species, all natives of warm climates. They are shrubby plants, rising from five to fourteen feet in height, adorned with flowers of a yellow colour.

HELIER, St. the capital of the island of Jersey, in the bay of St. Aubin. See **JERSEY**. Lon. 2. 10. W. Lat. 49. 11. N.

HELIER, St. a little island near the above town, on the side of Jersey; so named from St. Helier, a hermit, who lived in this island many centuries ago, and was slain by the Pagan Normans at their coming here.

HELIOCARPUS, in botany, a genus of the digynia order, and dodecandria class of plants; natural order, Columniferae. Calyx tetraphyllous; petals, four; styles, simple; capsule, bilocular, compressed, and radiated lengthwise on each side. One species, a native of America.

HELIOCENTRIC, [*heliocentrique*, Fr. $\eta\lambda\iota\omicron\varsigma$, and $\chi\epsilon\iota\tau\rho\omicron\nu$.] The heliocentric place of a planet is said to be such as it would appear to us from the sun, if our eye were fixed in its centre. See **ASTRONOMY**.

HELIOCENTRIC LATITUDE OF A PLANET, the inclination of a line drawn between the centre of the sun and the centre of a planet to the plane of the ecliptic. See **ASTRONOMY**.

HELIOCOMETES, a phenomenon sometimes observed about sun-setting; being a large luminous tail or column of light proceeding from the body of the sun, and dragging after it, like the tail of a comet; whence the name.

HELIOID PARABOLA, or the **PARABOLIC SPIRAL**, in mathematics, a curve which arises from the supposition of the axis of the common Apollonian parabola's being bent round into the periphery of a circle, and is a line then passing through the extremities of the ordinates, which do now converge towards the centre of the said circle.

HELIOMETER, [from $\eta\lambda\iota\omicron\varsigma$, the sun, and $\mu\epsilon\lambda\epsilon\tau\omega$, to measure,] an instrument called also astrometer, invented by M. Bouguer in 1747, for measuring with particular exactness the diameters of the stars, and especially those of the sun and moon. This instrument is a kind of telescope, consisting of two object-glasses of equal focus-distance placed the one by the side of the other, so that the same eye-glass serves for both. The tube is of a conic form, larger at the upper end, which receives the two object-glasses, than at the lower, which is furnished with an eye-glass and micrometer. By the construction of this instrument two distinct images of an object are formed in the focus of the eye glass, whose distance, depending upon that of the two object-glasses from one another, may be measured with great accuracy: nor is it necessary that the whole disk of the sun or moon come within the field of view; since, if the images of only a small part of the disk be formed by each object-glass, the whole diameter may be easily computed by their position with respect to one another: for if the object be large, the images will approach, or perhaps lie even

over one another; and the object-glasses being moveable, the two images may always be brought to touch one another, and the diameter may be computed from the known distance of the centres of the two glasses. Besides, as this instrument has a common micrometer in the focus of the eye-glass, when the two images of the sun or moon are made in part to cover one another, that part which is common to both the images may be measured with great exactness, as being viewed upon a ground that is only one-half less luminous than itself; whereas, in general, the heavenly bodies are viewed, upon a dark ground, and on that account are imagined to be larger than they really are. By a small addition to this instrument, provided it be of a moderate length, M. Bouguer thought it very possible to measure angles of three or four degrees, which is of particular consequence in taking the distance of stars from the moon. With this instrument M. Bouguer, by repeated observation, found, that the sun's vertical diameter, though somewhat diminished by the astronomical refraction, is longer than the horizontal diameter; and, in ascertaining this phenomenon, he also found, that the upper and lower edges of the sun's disk are not so equally defined as the other parts; on this account his image appears somewhat extended in the vertical direction. This is owing to the decomposition of light, which is known to consist of rays differently refrangible in its passage through our atmosphere. Thus the blue and violet-coloured rays, which proceed from the upper part of the sun's disk at the same time with those of other colours, are somewhat more refracted than the others, and therefore seem to us to have proceeded from a higher point; whereas, on the contrary, the red rays proceeding from the lower edge of the disk, being less refracted than the others, seem to proceed from a lower point; so that the vertical diameter is extended, or appears longer, than the horizontal diameter. Mr. Servington Savery discovered a similar method of improving the micrometer, which was communicated to the Royal Society in 1743. See **MICROMETER**.

HELIOPHILA, in botany, a genus of the siliquosa order, and tetradynamia class of plants; natural order, Siliquosae. Nectaria two, recurved towards the vesicular base of the calyx. It has ten species, natives of the Cape.

HELIOPHOBI, [from $\eta\lambda\iota\omicron\varsigma$, the sun, and $\phi\omicron\sigma\epsilon\omega$, to terrify,] a name given to the white negroes or albinos, from their aversion to the light of the sun.

HELIOPOLIS, an ancient city of Egypt, so called by Herodotus and Diodorus Siculus; by Moses On, and by Jeremiah Bethshemesh. It lies S. E. of the Delta, and E. of Memphis; and was long famous for its temple of the sun.

HELIOPELIS, a city of Coelosyria, near the springs of the Orontes; so called from the worship of the sun: now named Balbec. See **BALBEC**.

HELIOSCOPE, [$\eta\lambda\iota\omicron\varsigma$ and $\sigma\kappa\omicron\pi\omega$,] a sort of telescope fitted so as to look on the body of the sun, without offence to the eyes. Mr. Huygens only used a plain glass, blacked at the flame of a candle on one side, and placed between the eye-glass and the eye; which answers the design very well.

HELIOTATA, in optics, an instrument invented by the late learned Dr. S. Gravesende; who gave it this name from its fixing, as it were, the rays of the sun in a horizontal direction across the dark chamber all the while it is in use. See **OPTICS**.

HELIOTROPE, among the ancients, an instrument or machine for shewing when the sun arrived at the tropics and the equinoctial line. This name was also used for a sun-dial.

HELIOTROPE, in lithology, a precious stone of the flint genus, of a green colour, streaked with red veins. Pliny says it is thus called, because, when cast into a vessel of water, the sun's rays falling thereon seem to be of a blood-colour; and that, when out of the water, it gives a faint reflection of the figure of the sun; and is proper to observe eclipses of the sun, as a helioscope. It occurs massive in angular and rolled pieces; specific gravity about 2.7. It is found in the East Indies, as also in Ethiopia, Germany, Bohemia, &c. Some have ascribed to it the property of rendering people invisible, like Gyges's ring.

HELIOTROPIUM, [$\eta\lambda\iota\omicron\varsigma$ and $\tau\rho\omicron\pi\omega$,] **TURNSOLE**: a genus of the polygynia order, and pentandria class of plants; natural order, Asperitoliæ. Corolla salver-shaped, quinquefid, with less dents interjected alternately; throat closed up by small arches formed in the corolla itself. There are twenty-four species, all natives of warm countries.

HELIX, [ἑλῆξ,] literally signifies a wreath or winding; of ἑλίσσω, to environ.

HELIX, in anatomy, is the whole circuit or extent of the auricle or border of the ear outwards; whence the inner protuberance surrounded thereby, and answering thereto, is called antihelix. See **ANATOMY**.

HELIX, in architecture. Some authors make a difference between the helix and the spiral. A staircase, according to Daviler, is in a helix, or is helical, when the stairs or steps wind round a cylindrical newel; whereas the spiral winds round a cone, and is continually approaching nearer and nearer its axis. The word is also applied to the caulicules or little volutes under the flowers of the Corinthian capital; called also *urilla*. See **ARCHITECTURE**.

HELIX, the **SNAIL**, in zoology, a genus in the class *vermes*, and order *testacea*. Animal a *limax*; shell consists of one spiral, brittle, and almost diaphanous valve; aperture narrow, roundish. There are upwards of 300 species, principally distinguished by the figure of their shells. They are of various sizes, from that of a small apple to less than half a pea. Some of them live on land, frequenting woods and gardens, or inhabiting clefts of rocks and dry sand-banks. Others are aquatic, inhabiting ponds, deep rivers, and the ocean. They are separated into divisions; A. whorls, with a carinate acute margin; B. umbilicate, the whorls rounded; C. rounded imperforate; D. tapering; E. ovate, imperforate. See Plate LXVII.

H. HORTENSIS, **GARDEN-SNAIL**, has its shells imperforate, globular, pale, with broad interrupted brown bands: this species inhabits gardens and orchards in most parts of Europe, with a viscid slimy juice, which it readily gives out by boiling in milk or water, so as to render them thick and glutinous. The decoctions in milk are apparently very nutritious and demulcent, and have been recommended in a thin acrimonious state of the humours, in consumptive cases and emaciations. The eyes of snails are lodged in their horns, one at the end of each horn, which they can retract at pleasure. The manner of examining these eyes, which are four in number, is this: when the horns are out, cut off nimbly the extremity of one of them; and placing it before the microscope you may discover the black spot at the end to be really a semiglobular eye. The dissection of this animal is very curious; for the microscope not only discovers the heart beating just against the round hole near the neck, which seems the place of respiration, but also the liver, spleen, stomach, and intestines, with the veins, arteries, mouth, and teeth, are plainly observable. Snails are all hermaphrodites, having both sexes united in each individual. They lay their eggs with great care in the earth, and the young ones are hatched with shells completely formed. Cutting off a snail's head, a little stone appears, which is supposed to be a great diuretic, and good in all nephritic disorders. Immediately under this stone the heart is seen beating; and the auricles are evidently distinguishable, are membranous, and of a white colour; as are also the vessels which proceed from them. The snail, though a small animal, is not free from the plague of supporting other smaller animals on its body; and as in other animals we find these secondary ones either living only on their surface, as lice, &c. or only in the intestines, as worms, it is very remarkable that this creature infests the snail in both these manners; being found sometimes on the surface of its body, and sometimes within its intestines. There is a part of the common garden-snail, and of other of the like kinds, commonly called the collar. This surrounds the neck of the snail, and is considerably thick, and is the only part that is visible when the animal is retired quietly into its shell. In this state of the animal these insects which infest it are usually seen in considerable numbers marching about very nimbly on this part: besides, the snail, every time it has occasion to open its anus, gives them a place by which to enter into its intestines, and they often seize the opportunity. Snails are great destroyers of fruit in gardens, especially the better sorts of wall-fruit. Lime and ashes sprinkled on the ground where they most resort will drive them away, and destroy the young brood of them: it is a common practice to pull off the fruit they have bitten; but this should never be done, for they will eat no other till they have wholly eat up this if it be left for them.

H. JANTHINA, with a violet-coloured shell. This is remarkable for the extreme thinness of texture, which breaks with the least pressure, and seems therefore entirely calculated to keep the

open sea, or at least to shun rocky shores. It inhabits the seas of Europe, especially the Mediterranean; those of Asia and Africa; and also the ocean. The living animal, when touched, exudes a juice which stains the hands of a violet-colour.

H. FORMATIA, a snail with five spires remarkably ventricose, slightly umbilicated, fasciated with a lighter and deeper brown: this is found in the woods of the southern counties of England; it is said to have been introduced into this country by Sir Kenelm Digby, for medicinal purposes. These are confined to the southern counties, attempts having been made, but without success, to bring them into Northamptonshire. This snail is used in many parts of Europe as food, particularly at Rome during the weeks of Lent: here they are fattened, and grow to a very large size. It is oviparous, very tenacious of life, and, towards winter, covers its aperture with a calcareous lid.

HELL, [*helle*, Sax. a covered place, or a cavern; perhaps from *ελλος*, a lake, or from the Heb. *הול*, he was tormented,] signified formerly the place of separate spirits, but is now used for the place of divine punishment after death, in contradistinction to heaven. As all religions have supposed a future state of existence after this life, so all have their hell or place of torment, in which the wicked are supposed to be punished. The hell of the ancient heathens was divided into two mansions; the one called Elysium, on the right hand, pleasant and delightful, appointed for the souls of good men; the other called Tartarus, on the left, a region of misery and torment, appointed for the wicked. The latter only was hell, in the present restrained sense of the word. The philosophers were of opinion, that the infernal regions were at an equal distance from all the parts of the earth; nevertheless it was the opinion of some, that there were certain passages which led thither, as the river Lethe near the Syrtis, and the Acherusian cave in Epirus. At Hermione it was thought, that there was a very short way to hell; for which reason the people of that country never put the fare into the mouths of the dead to pay their passage. The Jews placed hell in the centre of the earth, and believed it to be situated under waters and mountains. The Mohammedans believe the eternity of rewards and punishments in another life. In the Koran it is said, that hell has seven gates, the first for the Mussulmans, the second for the Christians, the third for the Jews, the fourth for the Sabians, the fifth for the Magians, the sixth for the Pagans, and the seventh for hypocrites of all religions. Among Christians, there are two controverted questions in regard to hell; the one concerning the locality, the other the duration of its torments. 1. The locality of hell, and the reality of its fire, began first to be controverted by Origen. That father, interpreting the scripture-account metaphorically, makes hell to consist, not in external punishments, but in a consciousness or sense of guilt, and a remembrance of past pleasures. Among the moderns, Mr. Whiston advanced a new hypothesis. The comets, he thinks, are so many hells appointed in their orbits alternately to carry the damned into the confines of the sun, there to be scorched by its violent heat, and then to return with them beyond the orb of Saturn, there to starve them in those cold and dismal regions. Another modern author supposes the sun to be the local hell. 2. As to the duration of the torments, Origen is again at the head of those who deny that they are eternal; it being that father's opinion, that not only men, but devils, after a due course of punishment suitable to their respective crimes, shall be pardoned, and restored to heaven. The chief principle upon which Origen built his opinion, was the nature of punishment, which he took to be emendatory, applied only as physic for the recovery of the patient's health. The chief objection to the eternity of hell-torments, among modern writers, is the disproportion between temporary crimes and eternal punishments. Those who maintain the affirmative, ground their opinions on scripture-accounts, which represent the pains of hell under the figure of a worm which never dies, and a fire which is not quenched; as also upon the words, "These shall go away into everlasting punishment, but the righteous into life eternal." But, say their opponents, the character given by the Almighty of himself should decide the point: "His mercy is over all his works." Eternal punishment excludes every idea of mercy; and even of justice, for finite crimes can never merit infinite punishment. But here is certainly a mistake or two. Eternal punishment does not exclude every idea of mercy; for the very beings who suffer have rejected the infinite mercy of God to the ruin

ruin of their own souls. Neither does it exclude the idea of justice, for though it be true that finite crimes can never merit infinite punishment, yet it does not follow that because punishments are eternal they are therefore infinite. We are told that a finite creature is incapable of committing an infinite crime, the same argument will prove that he is incapable of infinite punishment, but it by no means proves him incapable of suffering eternal punishment. However, a man may seek to extenuate or lessen the idea of his crimes, it must be acknowledged that the very least breach of God's law is a crime inconceivably great, what then must be the magnitude of the total of the crimes of those, who have lived in the continual breach of all his laws, and to this have added the crimes of repeatedly rejecting infinite mercy: now it is granted that justice demands an adequate punishment, which must therefore be inconceivably great beyond all the comprehensions of the mind; what then hinders it to be eternal, as the clear revelation of God concerning it declares?

HELL, VALLEY OF, a valley of Suabia, in the Black Forest, through which, for many leagues, there is scarcely room for fifty men to march in front, the mountains rise so high on each side.

HELLAS, in ancient geography, an appellation comprising, according to the ancient Greeks and Romans, Achaia and Peloponnesus, but afterwards restrained to Achaia.

HELLE, in fabulous history, a daughter of Athamas king of Thebes by Nephele. She fled from her father's house with her brother Phryxus, to avoid the cruelty of her step-mother, Ino. According to some she was carried through the air on a ram with a golden fleece, which her mother had received from Neptune, and in her passage became giddy, and fell into that part of the sea, which from her received the name of Hellespont. Others say that she was carried on a cloud, or rather upon a ship, from which she fell into the sea and was drowned. See **PHRYXUS**.

HELLEBORE, WHITE. See **VERATRUM**.

HELLEBORUS, HELLEBORE: a genus of the polygynia order, and pentandria class of plants; natural order, Multisiliqua. Calyx none; petals five or more; nectaria bilabiate, tubular; capsules polyspermous, and a little erect. It has seven species.

H. NIGER, BLACK HELLEBORE, or CHRISTMAS-ROSE, has roots composed of many thick fleshy spreading fibres, crowned by a large cluster of lobed leaves, consisting each of seven or eight obtuse fleshy lobes, united to one foot-stalk; and between the leaves several thick fleshy flower-stalks three or four inches high, surmounted by large beautiful white flowers of five roundish petals, and numerous filaments, appearing in winter, about or soon after Christmas. It may be propagated either by seeds or parting the roots. It prospers in open borders, or may be planted in pots to move when in bloom, in order to adorn any particular place; but it always flowers fairest and most abundantly in the front of a warm sunny border. The plants may be removed, and the roots divided for propagation, in September, October, or November. On chewing the root for a few minutes, the tongue seems benumbed, and affected with a kind of paralytic stupor, as when burnt by eating any thing too hot. The fibres are more acrimonious than the head of the root from whence they issue. Black hellebore-root, taken from fifteen to thirty grains, proves a strong cathartic; and, as such, has been celebrated for the cure of maniacal and other disorders proceeding from what the ancients called the atra bilis; in which cases, medicines of this kind are doubtless occasionally of use, though they are by no means possessed of any specific power. It does not however appear, that our black hellebore acts with so much violence as that of the ancients; whence many have supposed it to be a different species of plant: and indeed the descriptions which the ancients have left us of their hellebore, do not agree with those of any of the sorts usually taken notice of by modern botanists.

H. NIGER ORIENTALIS is a species discovered in the eastern countries, which Tournefort distinguishes thus; amplissimum folio, caule praalto, flore purpureo, and supposes to be the true ancient hellebore, from its growing in plenty about mount Olympus, and in the island of Anticyra, celebrated of old for the production of this antimaniacal drug: he relates, that a scruple of this sort, given for a dose, occasioned convulsions.

HELLENISM, [*ἑλληνισμός*], a Greek idiom, used only when

speaking of the authors who, writing in a different language, express themselves in a phraseology peculiar to the Greek.

HELLENISTIC LANGUAGE, that used by the Grecian Jews who lived in Egypt and other parts where the Greek tongue prevailed. In this language it is said the Septuagint was written, and also the books of the New Testament, and that it was thus denominated to shew that it was Greek filled with Hebraisms and Syriasms.

HELLENISTS, or HELLENISTÆ, a term occurring in the Greek text of the New Testament, and which in the English version is rendered Grecians. The critics are divided as to the signification of the word. Eusebius, in his Scholia on Acts vi. 1, observes, that it is not to be understood as signifying those of the religion of the Greeks, but those who spoke Greek, *τῶν ἑλλήνων φηγομένων*. The authors of the Vulgate version, indeed, render it like ours, Græci; but Messieurs Du Port-Royal more accurately, Juifs Grecs, Greek or Grecian Jews; the Jews who spoke Greek being here treated of, and hereby distinguished from the Jews called Hebrews, that is, who spoke the Hebrew tongue of that time. These Hellenists, or Grecian Jews, were those who lived in Egypt and other parts where the Greek tongue prevailed. It is to them we owe the Greek version of the Old Testament, commonly called the Septuagint, or that of the LXX. Salmasius and Vossius, however, are of a different opinion, with regard to the Hellenists. The latter will only have them to be those who adhered to the Grecian interests. Scaliger is represented, in the Scaligerana, as asserting the Hellenists to be the Jews who lived in Greece and other places, and who read the Greek Bible in their synagogues, and used the Greek language in sacris; and thus they were opposed to the Hebrew Jews, who performed their public worship in the Hebrew tongue. In this sense St. Paul speaks of himself as a Hebrew of the Hebrews, (Phil. iii. 5,) *i. e.* a Hebrew both by nation and language. The Hellenists are thus properly distinguished from the Hellenes or Greeks, mentioned John xii. 20, who were Greeks by birth and nation, and yet proselytes to the Jewish religion.

HELLENODICE, [*ἑλληνοδικαί*], in antiquity, the directors of the Olympian games. At first there was only one, afterwards the number increased to two and three, and at length to nine. They assembled in a place called *ἑλληνοδικαίον*, in the Elean forum, where they were obliged to reside ten months before the celebration of the games, to take care that such as offered themselves to contend, performed their *προσγυμνασματα*, or preparatory exercises, and to be instructed in all the laws of the games by certain men called *νομοφύλακες*, *i. e.* keepers of the laws.

HELLESPONT, a narrow strait between Asia and Europe, near the Propontis, so named from Helle. It is now called the Dardanelles.

HELM, in ship-building, a long and flat piece of timber, or an assemblage of several pieces, suspended along the hind part of a ship's stern-post, where it turns upon hinges to the right or left, serving to direct the course of the vessel, as the tail of a fish guides the body. The helm is usually composed of three parts, *viz.* the rudder, the tiller, and the wheel, except in small vessels, where the wheel is unnecessary. As to the form of the rudder, it becomes gradually broader in proportion to its distance from the top, or to its depth under the water. The back, or inner part of it, which joins to the stern-post, is diminished into the form of a wedge throughout its whole length, so as that the rudder may be more easily turned from one side to the other, where it makes an obtuse angle with the keel. It is supported upon hinges; of which those that are bolted round the stern-post to the after extremity of the ship, are called googings, and are furnished with a large hole in the after-part of the stern-post. The other parts of the hinges, which are bolted to the back of the rudder, are called pintles, being strong cylindrical pins, which enter into the googings, and rest upon them. The length and thickness of the rudder is nearly equal to that of the stern-post. The rudder is turned upon its hinges by means of a long bar of timber, called the tiller, which is fixed horizontally in its upper end within the vessel. The movements of the tiller to the right and left, accordingly, direct the efforts of the rudder to the government of the ship's course as she advances; which, in the sea-language, is called steering. The operations of the tiller are guided and assisted by a sort of tackle, communicating with the ship's side, called the

the tiller-rope, which is usually composed of untarred rope-yarns for traversing more readily through the blocks or pulleys.

HELM, MANAGEMENT OF THE. To facilitate the management of the helm, the tiller-rope, in all large vessels, is wound about a wheel, which acts upon it with the powers of a crane or wind-flass. The rope employed in this service being conveyed from the fore-end of the tiller, to a single block on each side of the ship, is farther communicated to the wheel, by two blocks suspended near the mizen-mast, and two holes immediately above, leading up to the wheel, which is fixed upon an axis on the quarter-deck, almost perpendicularly over the fore-end of the tiller. Five turns of the tiller-rope are usually wound about the barrel of the wheel; and when the helm is amidship, the middle-turn is nailed to the top of the barrel, with a mark by which the helmsman readily discovers the situation of the helm, as the wheel turns it from the star-board to the larboard side. The spokes of the wheel generally reach about eight inches beyond the rim or circumference, serving as handles to the person who steers the vessel. As the effect of a lever increases in proportion to the length of its arm, it is evident that the power of the helmsman to turn the wheel will be increased according to the length of the spokes beyond the circumference of the barrel. When the helm, instead of lying in a right line with the keel, is turned to one side or the other, as in BD, Plate LXXXV. fig. 2, it receives an immediate shock from the water, which glides along the ship's bottom in running aft from A to B; and this fluid pushes it towards the opposite side, whilst it is retained in this position: so that the stern, to which the rudder is confined, receives the same impression, and accordingly turns from B to *b* about some point *c*, whilst the head of the ship passes from A to *a*. It must be observed, that the current of water falls upon the rudder obliquely, and only strikes it with that part of its motion which acts according to the sine of incidence, pushing it in the direction NP, with a force which not only depends on the velocity of the ship's course, by which this current of water is produced, but also upon the extent of the sine of incidence. This force is by consequence composed of the square of the velocity with which the ship advances, and the square of the sine of incidence, which will necessarily be greater or smaller according to circumstances; so that if the vessel runs three or four times more swiftly, the absolute shock of the water upon the rudder will be 9 or 16 times stronger under the same incidence: and, if the incidence is increased, it will yet be augmented in a greater proportion, because the square of the sine of incidence is more enlarged. This impression, or power of the helm, is always very feeble, when compared with the weight of the vessel; but as it operates with the force of a long lever, its efforts to turn the ship are extremely advantageous. For the helm being applied to a great distance from the centre of gravity G, or from the point about which the vessel turns horizontally, if the direction PN of the impression of the water upon the rudder be prolonged, it is evident that it will pass perpendicularly to R, widely distant from the centre of gravity G: thus the absolute effort of the water is very powerful. It is not therefore surprising, that this machine impresses the ship with a considerable circular movement, by pushing the stern from B to *b*, and the head from A to *a*; and even much farther whilst she sails with rapidity, because the effect of the helm always keeps pace with the velocity with which the vessel advances. Amongst the several angles that the rudder makes with the keel, there is always one position more favourable than any of the others, as it more readily produces the desired effect of turning the ship, in order to change her course. To ascertain this, it must be considered, that if the obliquity of the rudder with the keel be greater than the obtuse angle ABD, so as to diminish that angle, the action of the water upon the rudder will increase, and at the same time oppose the course of the ship in a greater degree; because the angle of incidence will be more open, so as to present a greater surface to the shock of the water, by opposing its passage more perpendicularly. But at that time the direction NP, of the effort of the helm upon the ship, will pass with a smaller distance from the centre of gravity G towards R, and less approach the perpendicular NL, according to which it is absolutely necessary that the power applied should act with a greater effect to turn the vessel. Thus it is evident, that if the obtuse angle ABD is too much inclosed, the greatest impulse of the water will not counterbalance

the loss sustained by the distance of the direction NP from NL, or by the great obliquity which is given to the same direction NP of the absolute effort of the helm with the keel AB. If, on the contrary, the angle ABD is too much opened, the direction NP of the force of the action of the helm will become more advantageous to turn the vessel, because it will approach nearer the perpendicular NL; so that the line prolonged from NP will increase the line GR, by removing R to a greater distance from the centre of gravity G: but then the helm will receive the impression of the water too obliquely, for the angle of incidence will be more acute; so that it will only present a small portion of its breadth to the shock of the water, and by consequence will only receive a feeble effort. By this principle it is easy to conceive, that the greatest distance GR from the centre of gravity G, is not sufficient to repair the diminution of force occasioned by the too great obliquity of the shock of the water. Hence we may conclude, that when the water either strikes the helm too directly, or too obliquely, it loses a great deal of the effect it ought to produce. Between the two extremes there is therefore a mean position, which is the most favourable to its operations. The diagonal NP of the rectangle IL represents the absolute direction of the effort of the water upon the helm. NI expresses the portion of this effort which is opposed to the ship's head-way, or which pushes her astern, in a direction parallel to the keel. It is easily perceived, that this part NI of the whole power of the helm contributes but little to turn the vessel; for, if IN is prolonged, it appears that its direction approaches to a very small distance GV from the centre of gravity G; and that the arm of the lever BN = GV, to which the force is applied, is not in the whole more than equal to half the breadth of the rudder: but the relative force NL, which acts perpendicular to the keel, is extremely different. If the first NI is almost useless, and even pernicious, by retarding the velocity; the second NL is capable of a very great effect, because it operates at a considerable distance from the centre of gravity G of the ship, and acts upon the arm of a lever GE, which is very long. Thus it appears, that between the effects NL and NI, which result from the absolute effort NP, there is one which always opposes the ship's course, and contributes little to her motion of turning; whilst the other produces only this movement of rotation, without operating to retard her velocity. Geometricians have determined the most advantageous angle made by the helm with the line prolonged from the keel, and fixed it at $54^{\circ} 44'$, presuming that the ship is as narrow at her floating line, or at the line described by the surface of the water round her bottom, as at the keel. But as this supposition is absolutely false, inasmuch as all vessels augment their breadth from the keel upward to the extreme breadth, where the floating-line or the highest water-line is terminated; it follows, that this angle is too large by a certain number of degrees. For the rudder is impressed by the water, at the height of the floating-line, more directly than at the keel, because the fluid exactly follows the horizontal outlines of the bottom; so that a particular position of the helm might be supposed necessary for each different incidence which it encounters from the keel upwards. But as a middle position may be between all these points, it will be sufficient to consider the angle formed by the sides of the ship, and her axis, or the middle-line of her length, at the surface of the water, in order to determine afterwards the mean point, and the mean angle of incidence. It is evident that the angle $54^{\circ} 44'$ is too open, and very unfavourable to the ship's head-way, because the water acts upon the rudder there with too great a sine of incidence, as being equal to that of the angle which it makes with the line prolonged from the keel below; but above, the shock of the water is almost perpendicular to the rudder, because of the breadth of the bottom, as we have already remarked. If then the rudder is only opposed to the fluid, by making an angle of 45° with the line prolonged from the keel, the impression, by becoming weaker, will be less opposed to the ship's head-way, and the direction NP of the absolute effort of the water upon the helm drawing nearer to the lateral perpendicular, will be placed more advantageously, for the reasons above mentioned. On the other hand, experience daily testifies, that a ship steers well when the rudder makes the angle DBE equal to 35° only. It has been already remarked, that the effect of moving the wheel to govern the helm increases in proportion to the length of the spokes; and

so great is the power of the wheel, that if the helmsman employs a force upon its spokes equivalent to 30lb. it will produce an effect of 90 or 120lb. upon the tiller. On the contrary, the action of the water is collected into the middle of the breadth of the rudder, which is very narrow in comparison with the length of the tiller; so the effort of the water is very little removed from the fulcrum B upon which it turns; whereas the tiller forms the arm of a lever 10 or 15 times longer, which also increases the power of the helmsman in the same proportion that the tiller bears to the lever upon which the impulse of the water is directed. This force then is by consequence 10 or 15 times stronger; and the effort of 30 pounds, which at first gave the helmsman a power equal to 90 or 120lb. becomes accumulated to one of 900 or 1800lb. upon the rudder. This disadvantage then arises from the shortness of the lever upon which the action of the water is impressed, and the great comparative length of the tiller, or lever, by which the rudder is governed; together with the additional power of the wheel that directs the movements of the tiller, and still farther accumulates the power of the helmsman over it. Such a demonstration ought to remove the surprise with which the prodigious effect of the helm is sometimes considered, from an inattention to its mechanism: for we need only to observe the pressure of the water, which acts at a great distance from the centre of gravity G, about which the ship is supposed to turn, and we shall easily perceive the difference there is between the effort of the water against the helmsman, and the effect of the same impulse against the vessel. With regard to the person who steers, the water acts only with the arm of a very short lever NB, of which B is the fulcrum: on the contrary, with regard to the ship, the force of the water is impressed in the direction NP, which passes to a great distance from G, and acts upon a very long lever EG, which renders the action of the rudder extremely powerful in turning the vessel; so that, in a large ship, the rudder receives a shock from the water of 2700 or 2800lb. which is frequently the case when she sails at the rate of three or four leagues by the hour; and this force being applied in E, perhaps 100 or 110 feet distant from the centre of gravity G, will operate upon the ship to turn her about, with 270,000 or 308,000lb; whilst, in the latter case, the helmsman acts with an effort which exceeds not 30lb. upon the spokes of the wheel. From what has been said, it is plain that the more a ship increases her velocity with regard to the sea, the more powerful will be the effect of the rudder; because its acts against the water with a force, which increases as the square of the swiftness of the fluid, whether the ship advances or retreats; or, in other words, whether she has head-way or stern-way; with this distinction, that in these two circumstances the effects will be contrary. For if the vessel retreats, or moves astern, the helm will be impressed from I to N; and instead of being pushed, according to NP, it will receive the effort of the water from N towards R; so that the stern will be transported to the same movement, and the head turned in a contrary direction. When the helm operates by itself, the centre of rotation of the ship, and her movement, are determined by estimating the force of this machine; that is to say, by multiplying the surface of the rudder by the square of the ship's velocity.

HELM, TERMS USED RESPECTING THE. In the sea-language, bear up the helm, signifies, let the ship go more at large before the wind: helm a mid-ship, or right the helm, is, keep it even with the middle of the ship: port the helm, put it over the left side of the ship; and starboard the helm, put it on the right side of the ship.

HELMET, armour for the head, it was anciently worn by horsemen both in war and in tournaments. It covered both the head and face, only leaving an aperture in the front secured by bars, which was called the visor. In achievements, it is placed above the escutcheon for the principal ornament, and is the true mark of chivalry and nobility. Helmets vary according to the different degrees of those who bear them. They are also used as a bearing in coats of arms. See **HERALDRY**.

HELMINTHOLITHUS, in natural history, a name given by Linnæus to petrified bodies resembling worms. Of these he reckons four genera: 1. Petrified lithophyta, found in the mountains of Sweden. 2. Petrified shells. 3. Petrified zoophytes. 4. Petrified reptiles.

HELMONT, JOHN BAPTIST VAN, a celebrated Flemish gen-

tleman, born at Brussels in 1577. He acquired such skill in natural philosophy, physic, and chemistry, that he was accounted a magician, and thrown into the inquisition: but having with difficulty justified himself, as soon as he was released he retired to Holland; where he died in 1644. He published, 1. *De Magnetica Corporum Curatione*. 2. *Febrium Doctrina Inaudita*. 3. *Ortus Medicinæ*. 4. *Paradoxa de Aquis Spadanis*; and other works, printed together in one vol. folio.

HELMONT, a small town of Batavia, in the department of Dommel and Scheldt, and late province of Dutch Brabant.

HELMSDALE, a river of Scotland, in Sutherland, called in the Celtic, Abhin liigh, or Avonuille, which rises from several lakes in the parish of Kildonan, and falls into the German Ocean.

HEMSLEY, a town of Yorkshire, on the Rye, twenty-two miles N. of York.

HELMSTADT, or **HALMSTADT**, a strong maritime town of Sweden, and capital of the province of Halland, on the Baltic. Lon. 12. 48. E. Lat. 56. 38. N.

HELONIAS, in botany, a genus of the trigynia order, and hexandria class of plants; natural order, Coronariæ. Corolla hexapetalous; no calyx; capsule trilocular. It has two species, American herbs.

HELOS, in ancient geography, a maritime town of Laconia, between Trinasus and Acridæ, in the district of Helotea. In Pausanias's time it was in ruins.

HELSINGFORS, a sea-port of Sweden, in the province of Nyland, on the N. coast of the Gulf of Finland, 140 miles E.S.E. of Abo.

HELSINGIA, or **HELSINGLAND**, a province of Sweden, bounded on the N. by Jemterland and Medelpadia; on the E. by the Bothnic Gulf; on the S. by Gestricia, and S.W. and W. by Dalecarlia. It is full of mountains and forests. The principal towns are Hudwicksvald, Alta, and Dilsbo. The rivers and lakes abound with fish. It is 120 miles long and 90 broad.

HELSINGIC CHARACTER, a peculiar character found on stones in Helsingia, resembling the Runic.

HELSTON, a populous borough of Cornwall, twelve miles E. of Penzance.

HELVETIA, or **CIVITAS HELVETIÆ**, in ancient geography, the country of the Helvetii, was divided into four Pagi or Cantons, situated to the S. and W. of the Rhine, by which they were divided from the Germans; and extending towards Gaul, from which they were separated by mount Jura on the W. and by the Rhodanus and Lacus Lemanus on the S. and therefore called a Gallic nation. It was formerly a part of Celtic Gaul, but by Augustus assigned to Gallia Belgica: lately called Switzerland, and now the Helvetic Republic.

HELVETIC REPUBLIC, one of the modern democratic States of Europe, formed by the French out of the late cantons of Switzerland.

HELVETII, a people of Gallia Belgica, near the country of the Allobroges and the Provincia Romana; famed for bravery and a turn for war; and not destitute of learning.

HELVOETSLUYS, a sea-port town of Batavia, in the department of Delft, island of Voorn, and late province of S. Holland. It is twelve miles W. of Dort, and fifteen S.W. of Rotterdam.

HEMEROBAPTISTS, a sect among the ancient Jews, thus called from their washing and bathing daily in all seasons; and performing this custom with the greatest solemnity, as a religious rite necessary to salvation, from *hama*, day, and *Sanctus*, I baptize.

HEMEROBIUS, in zoology, a genus of insects of the neuroptera order. Mouth furnished with two teeth; palpi are four; wings deflected, not plaited; antennæ bristly, longer than the breast. It has about forty species, principally distinguished by their colours. They are named hemerobii from the shortness of their lives, which, however, continue several days. In the state of larva they are great devourers of plant-lice, for which it has had the name of the lion of the plant-lice. They are also cannibals, and devour each other after their transformation. The eggs are borne on small gummy pedicles, spun by the insects from their abdomen. These eggs are deposited upon leaves, and set in the form of bunches. They have been taken for parasitic plants. In fifteen or sixteen days the larva attains to its full growth. With its spinning-wheel at its tail, it makes itself a small, round, white, silky,

silky cod, of a close texture. In summer, at the end of three weeks, the hemerobius issues forth with its wings; but when the cod has not been spun till autumn, the chrysalis remains in it the whole winter, and does not undergo its final metamorphosis till the next spring. The flight of this insect is heavy: some species have an excrementitious smell. See Plate LXXXVI. This genus is divided into two sections. A those having a membranaceous, annulate, cylindrical, lip. B having a vaulted, horny, lip.

HEMEROCALLIS, DAY-LILY, or LILY-ASPHODEL: a genus of the monogynia order, and hexandria class of plants; natural order, Coronaria. Corolla bell-shaped; the tube cylindric; stamina declining. There are five species.

HEMERODROMI, [from *ἡμερα*, day, and *δρομη*, course, &c.] among the ancients, were guards, appointed for the security of cities and other places.

HEMEROTROPHIS, [from *ἡμερα*, Gr. a day, and *τροφη*, food,] in antiquity, a measure of capacity, the same with the *choenix*; so called from its holding one day's food.

HEMI, [from *ἡμις*, Gr. half,] a word used in the composition of various terms, signifying the same with semi or demi, half.

HEMICYCLE, [of *ἡμις*, half, and *κύκλος*, circle,] a semicircle, is particularly applied, in architecture, to vaults in the cradle-form; and arches or sweeps of vaults, constituting a perfect semicircle.

HEMICYCLE, or **HEMICYCLIUM**, was also a part of the orchestra in the ancient theatre.

HEMICYCLE, or **HEMICYCLIUM**, was also used for a sort of sundial, the cusp whereof looked to the north.

HEMIMERIS, in botany, a genus of the angiospermia order, and didynamia class of plants. Essential character: calyx five-parted; corolla wheel-form; upper lip cloyen, with a nectareous bag at the base. There are three species.

HEMINA, in Roman antiquity, a liquid measure, which, according to Arbuthnot, was equal to half a wine-pint English measure; its contents being 2.818 solid inches.

HEMIOBOLON, a weight often mentioned by the ancient writers in medicines, signifying the half of the obolus, or the twelfth part of a drachm, i. e. five grains.

HEMIONITES, ENGLISH MULE-FERN, [from *hemisnus*, a mule,] in botany, a genus of the cryptogamia filices, or ferns. Capsules digested into lines, meeting together, either intersecting each other, or branched. There are eight species; natives of both the Indies.

HEMIPLEGY, [*ἡμις*, half, and *πλησσω*, to strike, or seize,] a palsy, or any nervous affection relating thereunto, that seizes one side at a time; some partial disorder of the nervous system. See MEDICINE.

HEMIPTERA, [from *ἡμις*, half, and *πτερον*, wing,] in the Linnæan system, the second order of insects, comprehending the following genera, viz. the blatta, mantis, gryllus, fulgora, cicada, notonecta, nepa, cimex, aphid, chermes, coccus, thrips, macrocephalus, and pneumora. See those articles, and ENTOMOLOGY.

HEMISPHERE, [*ἡμισφαίριον*,] in astronomy, is particularly used for one-half of the mundane sphere. The equator divides the sphere into two equal parts, called the northern and southern hemispheres. The horizon also divides the sphere into the upper and the lower hemispheres.

HEMISPHERE, is also used for a map, or projection, of half the terrestrial globe, or half the celestial sphere, on a plane. Hemispheres are frequently called planispheres.

HEMISPHERE, in geometry, the half of a globe or sphere, when it is supposed to be cut through its centre in the plane of one of its great circles. See GEOMETRY.

HEMISTIC, [*ἡμιστίχον*, *hemistiche*, Fr.] half a verse. It denotes also a verse not completed. Of this there are frequent examples in Virgil's *Æneid*; but whether they were left unfinished by design or not, is disputed among the learned: such are,

Ferro accincta vocat. *Æn.* II. v. 614.

And, Italian non sponte sequor. *Æn.* IV. 361.

In reading common English verses, a short pause is required at the end of each hemistich or half-verse.

HEMITONE, in the ancient music, was what we now call a half-note or semitone.

HEMITRITEUS, [from *ἡμις*, half, and *τρίτιος*, tertian,] in medicine, a kind of fever, denoting the same as semi-tertian, returning twice every day.

HEMLOCK. See CICUTA and CONIUM.

HEMODES, in ancient geography, seven islands of Denmark, now called Zealand, Fynen, Langeland, Muen, Falster, Lalandt, and Femeren.

HEMOIPTOTON. See ORATORY.

HEMORRHAGY. See HÆMORRHAGIA.

HEMORRHOIDS, [*ἡμορροΐδες*; *hemorrhoids*, Fr.] the piles; the emerods. See MEDICINE.

HEMP, [*hanep*, Sax. *hampe*, Dutch; *cannabis*.] See CANNABIS. It does not appear that the ancients were acquainted with the use of hemp, in respect of the thread it affords. Pliny, who speaks of the plant in his natural history, lib. xx. cap. 23, says not a word of this; but extols the virtues of its stem, leaves, and root. In effect, what some writers on the Roman antiquities remark, viz. that the hemp necessary for the use of war was all stored up in two cities of the western empire, viz. at Ravenna and Vienne, under the direction of two procurators, called procuratores linisicii, must be understood of linum or flax. The common hemp, or cannabis sativa, is a valuable plant, which grows wild in the East Indies, and is cultivated to a very considerable extent in Britain, particularly in the counties of Sussex and Suffolk. It thrives most favourably on a sandy, moist, loam, or on old meadows, and low bottoms; near rivers, and is propagated from seed, which is sown in the proportion of eleven pecks, or two bushels, per acre, broadcast; though a much smaller quantity will suffice, if it be drilled. The proper time of sowing hemp, is from the middle to the end of April, or even a month later; but the best crops are generally produced from the earlier seeds. This useful plant requires no weeding: the male, or fimbler-hemp, is usually fit for pulling in the middle of July, or about nine weeks after it is sown. The female, termed karle, or seed-hemp, is seldom ripe till September, when it is pulled, tied into bundles, and set to dry: at the end of ten days they are loosened, and the heads or tops are held upon a hurdle by one person, while another, with a small threshing-flail, beats out the seed. The hemp is then prepared for the manufacturer, either by grassing, that is, lying on stubble or pasture-ground, in order to be gradually dew-ripened; or, by water-ratting, for which process clay-pits are preferred to running-water. In these, the hemp is immersed in bundles, laid both directly, and across, for four or five days, according to the fineness of the weather. The next operation is that of reeding, namely, the separation of the bark from the reed, or woody part, which is effected either by pulling out the reed with the hand, or by drying, and breaking it by machinery, like flax. The hemp is then cleared of its mucilaginous matter, by pouring water through it, and squeezing out the liquid after every affusion, till it be completely divested of those particles. The next operation is that of breaking it, which, in the county of Suffolk, is performed with the aid of certain machinery worked by the hand; when the hemp is beaten in mills; combed or dressed by drawing it through heckles, similar to the combs of wool-manufacturers; and spun into thread, whence it is made into twine, cordage, cloth, netting, &c. Beside the strong cloth, and other articles made from it, hemp is of considerable utility for other purposes. The refuse, called hemp-sheaves, affords an excellent fuel; and the seeds yield by expression a pure oil, which is peculiarly adapted for burning in chambers, as it is perfectly limpid, and possesses no smell. Another valuable property of hemp is, that it effectually expels vermin from plantations of cabbages; for, if it be sown on the borders of fields, &c. planted with that vegetable, no caterpillars will infest it. When fresh, hemp has a strong, narcotic, smell: the water in which it has been soaked, is said to be in a high degree poisonous, and to produce fatal effects, immediately after drinking it. The seeds have an unctuous, sweetish, taste; they may be triturated with water, or boiled in milk as an emulsion, which is occasionally taken as a domestic remedy in coughs, heat of urine, and similar complaints. The important uses of hemp, and the superiority of that produced in this country, have justly rendered it an object of attention to government. Accordingly, in the year 1783 a bounty of 3d. per stone was granted on all hemp raised in Britain, in order to encourage its growth; and, with the same patriotic view, heavy duties are imposed on that article, when imported from foreign countries. On the other hand, its exportation both from Britain and Ireland, is duty-free.

HEMP-AGRIMONY. See EUPATORIUM.

HEMP-AGRIMONY, BASTARD. See AGERATUM.

HEMPSTED,

HEMPSTED, a town of Hertfordshire, eighteen miles S. W. of Hertford, and twenty-three N. W. of London.

HEN. See PHASIANUS.

HEN, GUINEA. See NUMIDA.

HENBANE. See HYOSCIAMUS.

HENDECAGON, [*ἑνδεκάγων*, and *γωνία*,] a figure of eleven sides or angles.

HENDECASYLLABON, in grammar, a word consisting of eleven syllables, from the Greek words *ἑνδεκά*, eleven, and *συλλαβή*, a syllable.

HENDIADIS, [*ἑνδιὰς*, Gr.] a figure in rhetoric, when two substantive-nouns are used for a substantive and adjective.

HEN-MOUL SOIL, in agriculture, a term used by the husbandmen in Northamptonshire, and other counties, to express a black, hollow, spongy, and mouldering earth, usually found at the bottoms of hills.

HENNEAMIMERIS, in poetry, a verse of nine half-feet.

HENNEBERG, a mountainous country in Franconia.

HENNEBERG, a town in the above country, thirty-four miles N. W. of Bamberg.

HENNEBON, a town of France, in the department of Morbihan, and late province of Bretagne; 22 miles N. W. of Vannes, and 260 W. by S. of Paris.

HENOTICUM, [*ἑνωτικόν*, *q. d.* reconciliative; of *ἑνω*, I unite,] in church-history, a famous edict of the emperor Zeno, published A. D. 482, and intended to re-unite the Eutychians with the Catholics.

HENRICHEMONT, a town of France, in the department of Cher, and late province of Berry, twelve miles and a half N. N. E. of Bourges.

HENRY, the name of eight emperors of Germany, and one of Constantinople; of eight kings of England, four of France, four of Spain, one of Portugal, and one of Scotland. Our limits will not permit us to give an account of each of these, we therefore refer the reader to the histories of the countries where these monarchs reigned.

HENRY, MATTHEW, an eminent dissenting minister, born in 1662. He continued under his father's care till he was eighteen years of age; in which time he became well skilled in the learned languages, especially in the Hebrew, which his father had rendered familiar to him from his childhood; and from first to last the study of the Scriptures was his most delightful employment. He completed his education in Mr. Doolittle's academy at Islington, and was afterwards entered in Gray's-Inn for the study of the law. But at length, resolving to devote his life to divinity, in 1686 he retired into the country, and was chosen pastor of a congregation at Chester, where he lived about twenty-five years, greatly esteemed and beloved by his people. He had several calls to London, which he constantly declined; but was at last prevailed upon to accept an unanimous invitation from a congregation at Hackney. He wrote, 1. Expositions of the Bible, in 5 vols. folio. 2. The Life of Mr. Philip Henry. 3. Directions, for daily Communion with God. 4. A Method for Prayer. 5. Four Discourses against Vice and Immorality. 6. The Communicant's Companion. 7. Family Hymns. 8. A Scriptural Catechism. And, 9. A Discourse concerning the Nature of Schism. He died of an apoplexy at Nantwich, in 1714; and was interred at Trinity church in Chester.

HENRY, ROBERT, D. D. a Scotch divine, was born at St. Ninian's in 1718, and educated at Edinburgh. In 1748 he was ordained as a Presbyterian minister at Carlisle. He afterwards removed to Berwick, and in 1768 to Edinburgh, where he became minister of the New Gray-friars church. In 1776 he was chosen one of the ministers at the Old church, and died in 1790. Dr. Henry is known as the author of a valuable history of Great Britain, to the reign of Henry VII. which has gone through several editions. This work arranges, under separate heads, the civil and military history of Great Britain; the history of religion; the history of our constitution, government, laws, and courts of justice; the history of learning, of learned men, and of the chief seminaries of learning; the history of arts; the history of commerce, of shipping, of money or coin, and of the price of commodities; and the history of manners, virtues, vices, customs, language, dress, diet, and amusements. Under these seven heads, which extend the province of an historian greatly beyond its usual limits, every

thing curious or interesting in the history of any country may be comprehended.

HENTING, in agriculture, a term used by the farmers for a particular method of sowing before the plough; the corn, being cast into a straight line just where the plough is to come, is by this means presently ploughed in. By this way of sowing they think they save a great deal of seed and other charges, a dexterous boy being as capable of sowing this way out of his hat as the most skilful seedsman. Henting is also a term used by the ploughmen, and others, to signify the two furrows that are turned from one another at the bottom, in the ploughing of a ridge. The word seems to be a corruption of ending, because those furrows made an end of ploughing the ridges. The tops of the ridges they call veerings.

HEPAR, the LIVER. See ANATOMY.

HEPAR SULPHURIS, or LIVER OF SULPHUR, a combination of alkali and sulphur. It is now denominated sulphuret. See SULPHURET.

HEPATICE ARTERIE. See ANATOMY.

HEPATIC GAS, the gas which is now called sulphuretted hydrogen gas. See GAS.

HEPATITIS, in medicine, an inflammation of the liver. See MEDICINE.

HEPATOSCOPIA, [from *ἥπαρ*, liver, and *σκοπεω*, I consider,] in antiquity, a species of divination, wherein predictions were made by inspecting the livers of animals. The word was also used for divination by entrails.

HEPHÆSTIA, in antiquity, an Athenian festival in honour of Vulcan, the chief ceremony of which was a race with torches.

HEPHÆSTUS, [*Ἡφαίστος*, from *ἥφα*, I have kindled, and *ἑστια*, a fire,] the Greek name of Vulcan.

HEPHTHEMIMERIS, [of *ἑπτα*, seven, *ἡμισυς*, and *μέτρον*, part,] in the Greek and Latin poetry, a sort of verses consisting of three feet and a syllable; that is, of seven half-feet: called also trimetri catalectici. Such are most of the verses in Anacreon:

Θεῶν	λιν	ἄτρει	δὲς
Θεῶν	δε Κεῖ	μον α	δὲν, &c.

And that of Aristophanes, in his *Plutus*:

Ἐπεσθε μάλιστα χοῖροι.

HEPHTHEMIMERIS, or HEPHTHEMIMERES, is also a cæsura after the third foot; that is, on the seventh half-foot. It is a rule, that this syllable, though it be short in itself, must be made long on account of the cæsura, or to make it an hephthemimeris. As in that verse of Virgil.

“Et furis agitatus amor, et conscia virtus.”

HEPS, or HIPS, HEP-TREE. See ROSA.

HEPTACAPSULAR [*ἑπτά*, Gr. and *capsula*, Lat.] having seven cavities or cells.

HEPTACHORD, in ancient poetry, signified verses that were sung or played on seven chords, *i. e.* on seven different notes. In this sense it was applied to the lyre when it had but seven strings. One of the intervals is also called an heptachord, as containing the same number of degrees between the extremes.

HEPTAGON, [*heptagone*, Fr. *ἑπτάγων*, and *γωνία*,] a figure with seven sides or angles.

HEPTAGON, in fortification, a place that has seven bastions for its defence. See GEOMETRY and MENSURATION.

HEPTAGONAL NUMBERS, are a kind of polygonal numbers in which the difference of the terms of the corresponding arithmetical progression is 5. Thus,

Arithmeticals, 1, 6, 11, 16, 21, 26, &c.

Heptagonals, 1, 7, 18, 34, 55, 81, &c.

where the heptagonals are formed by adding continually the terms of the arithmeticals, above them, whose common difference is 5. One property, among many others, of these heptagonal numbers is, that if any one of them be multiplied by 40, and to the product 9 be added, the sum will be a square number.

Thus	1 × 40	+ 9	=	49	= 7 ²
and	7 × 40	+ 9	=	289	= 17 ²
and	18 × 40	+ 9	=	729	= 27 ²
and	34 × 40	+ 9	=	1369	= 37 ² , &c.

Where it is remarkable that the series of squares so formed is 7², 17², 27², 37², &c. the common difference of whose root is 10, the

double of the common difference of the arithmetical series from which the heptagonals are formed. See POLYGONALS.

HEPTANDRIA, [from *ἑπτα*, seven, and *ανδρ*, a man,] in botany, the seventh class in Linnæus's sexual method, consisting of plants with hermaphrodite flowers, which have seven stamina or male organs. See BOTANY.

HEPTANGULAR, in geometry, having seven angles.

HEPTARCHY, [*heptarchie*, Fr. *ἑπτα* and *αρχη*,] a government composed of seven persons, or a country governed by seven persons, or divided into seven kingdoms. The Saxon heptarchy included all England, which was cantoned out into seven independent kingdoms, peopled and governed by different clans and colonies, viz. those of Kent, the South Saxons, West Saxons, East Saxons, Northumberland, the East Angles, and Mercia.

HERACLEA, an ancient city of European Turkey in Romania, 45 miles W.S.W. of Constantinople.

HERACLEONITES, a sect of heretics, the followers of Heracleon, who refined upon the Gnostic system, and maintained that the world was not the immediate production of the Son of God, but that he was only the occasional cause of its being created by the Demiurgus. The Heracleonites denied the authority of the Old Testament, maintaining that they were mere random-sounds in the air; and that St. John the Baptist was the only true voice that directed to the Messiah.

HERACLEUM, **COW-PARSNIP**; a genus of the digynia order, and pentandria class of plants; natural order Umbellatæ. Fruit elliptical, emarginated, compressed, striated, with a thin border; corolla difform, inflexed, emarginated; involucre dropping off. It has six species.

HERACLIDÆ, the descendants of Hercules, greatly celebrated in ancient history. Hercules, at his death, left his son Hyllus all the rights and demands which he had upon Peloponnesus, and ordered him to marry Iole, the daughter of Eurystheus, as soon as he came of age. The posterity of Hercules were not more kindly treated by Eurystheus than their father had been, and they were obliged to retire for protection to the court of Ceyx, king of Trachinia. Eurystheus pursued them thither; and Ceyx, afraid of his resentment, begged the Heraclidæ to depart from his dominions. From Trachinia they came to Athens, where king Theseus, who had accompanied their father in some of his expeditions, received them with great humanity, and assisted them against Eurystheus. Eurystheus was killed by Hyllus himself; his children perished with him, and all the cities of Peloponnesus became the indisputed property of the Heraclidæ. Their triumph, however, was short; their numbers were lessened by a pestilence; and the oracle informed them, that they had taken possession of Peloponnesus before the gods permitted their return. Upon this they abandoned Peloponnesus, and came to settle at Attica, where Hyllus married Iole. Soon after he consulted the oracle, anxious to recover the Peloponnesus; and the ambiguity of the answer determined him to make a second attempt. He challenged to single combat Atreus, the successor of Eurystheus on the throne of Mycenæ; and it was mutually agreed that the undisturbed possession of Peloponnesus should be ceded to the victor. Echemus accepted the challenge for Atreus; Hyllus was killed, and the Heraclidæ departed from Peloponnesus a second time, about twenty years before the Trojan war. Cleodæus, the son of Hyllus, made a third attempt, and was equally unsuccessful; and his son Aristomachus, some time after, met with the same unfavourable reception, and perished in the field of battle. Aristodemus, Temenus, and Chresphontes, the three sons of Aristomachus, encouraged by the more express word of an oracle, and desirous to revenge the death of their progenitors, assembled a numerous force, and with a fleet invaded all Peloponnesus. Their expedition was attended with much success; and after some decisive battles they became masters of all the peninsula. The recovery of

Peloponnesus by the Heraclidæ forms an interesting epoch in ancient history, which is universally believed to have happened eighty years after the Trojan war, B. C. 1104. This conquest was totally achieved about a hundred and twenty years after the first attempt of Hyllus, who was killed about twenty years before the Trojan war. As it occasioned many changes and revolutions in the affairs of Greece, the return of the Heraclidæ is the epocha of the beginning of profane history: all the time that preceded it is reputed fabulous. Accordingly, Ephorus, Cumeus, Callisthenes, and Theopompus, begin their histories from this era.

HERACLIDES, a Greek philosopher of Pontus, the disciple of Speusippus, and afterwards of Aristotle, flourished about B. C. 336. His vanity prompted him to desire one of his friends to put a serpent into his bed just as he was dead, in order to raise a belief that he was ascended to the heavens among the gods; but the cheat was discovered. All his works are lost.

HERACLITUS, a famous Ephesian philosopher, who flourished about the sixty-ninth Olympiad, in the time of Darius Hystaspes. He is said to have continually bewailed and wept for the wicked lives of men; contrary to Democritus, who made the follies of mankind a subject of laughter. He retired to the temple of Diana, and played at dice with the boys there; saying to the Ephesians who gathered round him, "Worst of men, what do you wonder at? Is it not better to do thus than to govern you?" Darius invited him to come and live with him, but he refused. At last, out of hatred to mankind, he retired to the mountains, where he contracted a dropsy, by living on herbs, which killed him at sixty years of age. His writings gained him great reputation. Laertius mentions a Treatise upon Nature, divided into three books, concerning the universe: the second on politics: the third on theology. This book he deposited in the temple of Diana; and it is said that he affected to write obscurely, lest it should be read by the vulgar, and become contemptible. The fundamental doctrine of his philosophy was, that fire is the principle of all things.

HERALD, [from the Saxon word *Herehault*, a champion of an army,] a term formerly applied to him who, in the army, had the special charge to denounce war, to challenge to battle and combat, to proclaim peace, and to execute martial messages. But the business of heralds, now, is as follows, viz. to marshal, order, and conduct, all royal cavalcades, ceremonies at coronations, royal marriages, installations, creations of dukes, marquises, earls, viscounts, barons, baronets, and dubbing of knights; embassies, funeral-processions, declarations of war, proclamations of peace, &c.: to record and blazon the arms of the nobility and gentry; and to regulate any abuses therein through the British dominions, under the authority of the Earl Marshal, to whom they are subservient. The office of Windsor, Chester, Richmond, Somerset, York, and Lancaster heralds, is to be assistants to the kings at arms, in the different branches of their office; and they are superior to each other, according to creation, in the above order. Heraldry was anciently held in much greater esteem than they are at present; and were created and christened by the king, who, pouring a goldcup of wine on their head, gave them the herald-name: but this is now done by the Earl Marshal. They could not arrive at the dignity of herald without being seven years pursuivant; nor quit the office of herald, but to be made king at arms. Richard III. was the first who formed them, in this kingdom, into a college; and afterwards great privileges were granted them by Edward VI. and Philip and Mary. The origin of heralds is very ancient. Stentor is represented by Homer as herald of the Greeks, who had a voice louder than fifty men together. The Greeks called them *μηνυτεις*, and *μηνυφουδαιες*; and the Romans, *feciales*. The Romans had a college of heralds, appointed to decide whether a war were unjust; and to prevent its coming to open hostilities, till all means had been attempted for deciding the difference in a pacific way.

HERALDRY.

HERALDRY, [*herauldrie*, Fr. from *herehault*, Sax.] is a science which teaches how to blazon, or explain in proper terms, all that belongs to arms; and how to marshal, or dispose regularly, divers arms on a field. It also teaches whatever relates to the marshalling of solemn cavalcades, processions, and other public cere-

monies at coronations, installations, creations of peers, nuptials, christenings of princes, funerals; &c. Arms, or coats of arms, are hereditary marks of honour, made up of fixed and determined colours and figures, granted by sovereign princes, as a reward for military valour, or some signal public service; and serve to denote the

the descent and alliance of the bearer, or to distinguish states, cities, societies, &c. civil, ecclesiastical, and military. Sir John Ferne is of opinion, that we borrowed arms from the Egyptians; meaning from their hieroglyphics. Sir William Dugdale mentions, that arms, as marks of honours were first used by great commanders in war, necessity requiring that their persons should be notified to their friends and followers. The learned Alexander Nisbet, in his excellent System of Heraldry, says, that arms owe their rise and beginning to the light of nature, and that signs and marks of honour were made use of in the first ages of the world, and by all nations, however simple and illiterate, to distinguish the noble from the ignoble. We find in Homer, Virgil, and Ovid, that their heroes had divers figures on their shields, whereby their persons were distinctly known. Alexander the Great, desirous to honour those of his captains and soldiers who had done any glorious action, and also to excite an emulation among the rest, granted them certain badges to be borne on their armour, pennons, and banners; ordering, at the same time, that no person or potentate, through his empire, should attempt or presume to give or tolerate the bearing of those signs upon the armour of any man, but it should be a power reserved to himself; which prerogative has been claimed ever since by all other kings and sovereign princes within their dominions. On this subject, all that can be said with any certainty is, that in all ages, men have made use of figures of living creatures, or symbolical signs, to denote the bravery and courage either of their chief or nation, to render themselves more terrible to their enemies, and even to distinguish themselves or families, as names do individuals. The famous C. Agrippa, in his treatise of the vanity of sciences, cap. 81, has collected many instances of these marks of distinction, anciently borne by kingdoms and states that were any way civilized, viz. the Egyptians bore an ox; the Athenians an owl; the Goths a bear; the Romans an eagle; the Franks a lion; and the Saxons a horse. As to hereditary arms of families, William Cambden, Sir Henry Spelman, and other judicious heralds, agree, that they did not begin till towards the end of the eleventh century. These marks of honour are called arms, from their being principally and first worn by military men at war and tournaments, who had them engraved, embossed, or depicted, on shields, targets, banners, or other martial instruments. They are also called Coats of Arms, from the custom of the ancients embroidering them on the coats they wore over their arms as heralds do to this day. Arms are distinguished by different names, to denote the causes of their bearing: such as, arms of Dominion, of Pretension, of Concession, of Community, of Patronage, of Family, of Alliance, of Succession.

ARMS OF DOMINION, or SOVEREIGNTY, are those which emperors, kings, and sovereign states, constantly bear; being, as it were, annexed to the territories, kingdoms, and provinces, they possess. Thus the three lions are the arms of England, the fleur-de-lis those of the late monarchy of France, &c.

ARMS OF PRETENSION are those of such kingdoms, provinces, or territories, to which a prince or lord has some claim, and which he adds to his own, although the said kingdoms or territories be possessed by a foreign prince or other lord.

ARMS OF CONCESSION, or augmentation of honour, are either entire arms, or else one or more figures, given by princes as a reward for some great service. We read in history, that Robert Bruce, King of Scotland, allowed the Earl of Winton's ancestor to bear, in his coat-armour, a crown supported by a sword, to shew that he, and the clan Seaton, of which he was the head, supported his tottering crown.

ARMS OF COMMUNITY are those of bishoprics, cities, universities, academies, societies, companies, and other bodies corporate.

ARMS OF PATRONAGE are such as governors of provinces, lords of manors, patrons of benefices, &c. add to their family-arms, as a token of their superiority, rights, and jurisdiction. These arms have introduced into heraldry, castles, gates, wheels, ploughs, rakes, harrows, &c.

ARMS OF FAMILY, or PATERNAL ARMS, are those that belong to one particular family, that distinguish it from others, and which no person is suffered to assume without committing a crime, which sovereigns have a right to restrain and punish.

ARMS OF ALLIANCE are those which families or private persons take up and join to their own, to denote the alliances they have contracted by marriage. This sort of arms is either impaled, or

borne in an escutcheon of pretence, by those who have married heiresses.

ARMS OF SUCCESSION are such as are taken up by those who inherit certain estates, manors, &c. either by will, entail, or donation, and which they either impale or quarter with their own arms; which multiplies the titles of some families out of necessity, and not through ostentation, as many imagine. These are the eight classes under which the various sorts of arms are generally ranged; but there is a sort which blazoners call assumptive arms, being such as are taken up by the caprice or fancy of upstarts, though of ever so mean extraction, who, being advanced to a degree of fortune, assume them without a legal title. This, indeed, is a great abuse of heraldry; and common only in Britain, for on the continent no such practice takes place. The essential and integral parts of arms are these: 1. The **ESCUTCHEON**: 2. The **TINCTURES**: 3. The **CHARGES**: 4. The **ORNAMENTS**.

OF THE SHIELD OR ESCUTCHEON.

The Shield or Escutcheon is the field or ground whereon are represented the figures that make up a coat of arms: for these marks of distinction were put on bucklers or shields before they were placed on banners, standards, flags, and coat-armour; and wherever they may be fixed, they are still on a plane or superficies whose form resembles a shield. Shields, escutcheons, or scutcheons, are of different forms, according to different times and nations. Amongst ancient shields, some were almost like a horse-shoe such as is represented in the figure of Escutcheons, Plate LXXXVI. others triangular, somewhat rounded at the bottom. That of knights banneret was square, like a banner. As to modern escutcheons, those of the Italians, particularly of ecclesiastics, are generally oval. The English, French, Germans, and other nations, have their escutcheons formed different ways, according to the carver's or painter's fancy: see the various examples in the plates. But the escutcheons of maids, widows, and of such as are born ladies, and are married to private gentlemen, is in the form of a lozenge. Amorists distinguish several parts or points in escutcheons, in order to determine exactly the position of the bearings they are charged with; they are here denoted by the first nine letters of the alphabet ranged in the following manner:

- A — the dexter chief.
- B — the precise middle chief.
- C — the sinister chief.
- D — the honour point.
- E — the fess point.
- F — the nombril point.
- G — the dexter base.
- H — the precise middle-base.
- I — the sinister base.

The knowledge of these points is of great importance, for they are frequently occupied with several things of different kinds. The dexter side of the escutcheon is opposite to the left hand, and the sinister side to the right of the hand of the person that looks on it.

OF TINCTURES.

By tinctures is meant, that variable hue of arms which is common both to shields and their bearings. The seven tinctures chiefly used are differently expressed as follows.

The Proper Colours.	By tinctures for Commoners.	By Precious Stones for Peers.	By Planets for Princes, Kings, and Emperors.
Yellow	Or	Topaz	Sol
White	Argent	Pearl	Luna
Red	Gules	Ruby	Mars
Blue	Azure	Sapphire	Jupiter
Purple	Purpure	Amethyst	Mercury
Black	Sable	Diamond	Saturn
Green	Vert	Emerald	Venus

When natural bodies, such as animals, plants, celestial bodies, &c. are

&c. are introduced into coats of arms, they frequently retain their natural colours, which is expressed in this science by the word proper. Besides the colours abovementioned, the English writers on heraldry admit two others, viz.

Orange,
Blood-colour, } termed { Tenny.
Sanguine.

But these two are rarely to be found in British bearings. These tinctures are represented in engravings and drawings (the invention of the ingenious Silvester Petra Sancta, an Italian author of the last century) by dots and lines, as in Plate LXXXVI. Or is expressed by dots. Argent needs no mark, and is therefore plain. Azure, by horizontal lines. Gules, by perpendicular lines. Vert, by diagonal lines from the dexter chief to the sinister base points. Purpure, by diagonal lines from the sinister chief to the dexter base points. Sable, by perpendicular and horizontal lines crossing each other. Tenny, by diagonal lines from the sinister chief to the dexter base points, traversed by horizontal lines. Sanguine, by lines crossing each other diagonally from dexter to sinister, and from sinister to dexter. The English heralds give different names to the roundlet, according to its colour. Thus, if it be Or, it is called a Bezant; Argent, a Plate; Azure, a Hurt; Gules, a Torteaux; Vert, a Pomey; Purpure, a Golpe; Sable, a Pellet; Tenny, an Orange; and Sanguine, Guze.

OF FURS.

Furs represent the hairy skin of certain beasts, prepared for the doublings or linings of robes and garments of state; and as shields were anciently covered with furred skins; they are therefore used in heraldry, and are,

1. *Ermine*; which is a field-argent, powdered with black spots, their tails terminating in three hairs.
2. *Ermines*; or *Counter-ermine*, where the field is sable, and the powdering white.
3. *Erminoise*; the field Or, the powdering Sable.
4. *Vair*, which is expressed by blue and white skins, cut into the forms of little bells, ranged in rows opposite to each other, the base of the white ones being always next to that of the blue ones. Vair is usually of six rows; if there be more or fewer, the number ought to be expressed; and if the colours are different from those above mentioned, they must likewise be expressed.
5. *Pean*; the field is Sable, the powdering Or.
6. *Potent*, anciently called *Vairy-cuppy*, as when the field is filled with crutches or potents counter-placed. Vair and Potent may be any two colours. See Plate LXXXVI.

OF THE LINES USED IN THE PARTING OF FIELDS.

Escutcheons are either of one tincture, or more than one. Those that are of one only, that is, when some metal, colour, or fur, is spread all over the surface or field, such a tincture is said to be predominant: but in such as have on them more than one, as most have, the field is divided by lines; which according to their divers forms, receive various names. Lines may be either straight or crooked. Straight lines are carried evenly through the escutcheon: and are of four different kinds; viz. a perpendicular line |; a horizontal, —; a diagonal dexter, /; a diagonal sinister, \. Crooked lines are those which are carried unevenly through the escutcheon with rising and falling, the figures and names of which are as in Plate LXXXVI. viz. 1. The engrailed. 2. The invected. 3. The wavy. 4. The nebule. 5. The embattled or crenelle. 6. The raguly. 7. The indented. 8. The dancette. 9. The dove-tail. The principal reason why lines are thus used in heraldry, is to difference bearings which would be otherwise the same; for an escutcheon charged with a chief engrailed differs from one charged with a chief wavy, as much as if the one bore a cross and the other a saltier. As the forementioned lines serve to divide the field, if the division consists of two equal parts made by the perpendicular line, it is called parted per pale; by the horizontal line, parted per fess; by the diagonal dexter, parted per bend; by the diagonal sinister, parted per bend sinister; examples of which will be given in the sequel of this treatise. If a field be divided into four equal parts by any of these lines, it is said to be quartered; which may be done two ways, viz. Quartered or parted per cross; which is made by a perpendicular and horizontal line, which, crossing each other at the centre of the field, divide it

into four equal parts called quarters. Quartered or parted per saltier; which is made by two diagonal lines, dexter and sinister, that cross one another in the centre of the field, and likewise divide it into four equal parts. The escutcheon is sometimes divided into a greater number of parts, in order to place in it the arms of the several families to which one is allied; and in this case it is called a genealogical achievement. These divisions may consist of six, eight, 12, and 16, quarters, [as the royal arms,] and even sometimes of 20, 32, 64, and upwards; there being examples of such divisions frequently exhibited at pompous funerals. But Sir William Dugdale very justly objects to so many arms being clustered together in one shield or banner, on account of the difficulty of discerning and knowing asunder one coat of arms from another.

OF THE DIFFERENCES OF COATS OF ARMS.

Armorists have invented many differences or characteristical marks, whereby bearers of the same coat of arms are distinguished each from others, and their nearness to the principal bearer demonstrated. According to J. Guillim, these differences are to be considered either as ancient or modern. Those he calls ancient differences consist in bordures; which is a bearing that goes all round, and parallel to the boundary of the escutcheon. Bordures were used in ancient times for the distinguishing not only of one nation or tribe from another, but also to note a diversity between particular persons descended of one family and from the same parents. The bordure is generally one-sixth part of the breadth of the shield, and is engrailed, indented, charged, componed, and countered. If the inner line of the bordure is straight and the latter plain, the colour of the bordure alone is named in blazoning; if it is charged with parts of plants or flowers, it is described as verdoy of trefoils. If it consists of ermines, Vair or vairy, or any of the furs, the heralds say purflew of ermines. When charged with martlets, charged with an enaluron of martlets. There are bordures of different forms and tinctures, as in the examples, in Plate LXXXVI. Bordures are generally used as a difference between families of the same name, and also as marks of illegitimacy. The modern differences, which the English have adopted, not only for the distinguishing of sons issued out of one family, but also to denote the difference and subordinate degrees in each house from the original ancestors, are nine, viz. For the heir or first son, the Label. Second son, the Crescent. Third son, the mullet. Fourth son, the martlet. Fifth son the Annulet. Sixth son, the Flower-de-lis. Seventh son, the Rose. Eighth son, the Cross-moline. Ninth son, the Double Quarter foil. See Plate LXXXVI. But of all these marks of distinction, none but the label is affixed on the coats of arms belonging to any of the royal family. As to the distinction to be made in the arms of the offspring belonging to each of the above-mentioned brothers, it is expressed by figures on the table of houses, given in Plate LXXXVI. For instance, The heir or first son of the second house, bears a crescent charged with a label during his father's life only. The second son of the second house, a crescent charged with another crescent. The third son of the second house, a crescent charged with a mullet. The fourth son of the second house, a crescent charged with a martlet. The fifth son of the second house, a crescent charged with an annulet. The sixth son of the second house, a crescent charged with a fleur-de-lis; and so on of the other sons, taking care to have them of a different tincture. In like manner the seventh son of the eighth house, a rose charged with a cross moline; this is easily understood, though the table does not extend so far. The daughters of families are permitted to bear their fathers arms, with the same distinctions used by them. An abatement is a casual mark annexed to coat-armour, which announces some dishonourable act of the bearer. Abatements consist of diminution and reversing, the first is the blemishing of some particular point of the escutcheon by sanguine and tennue, which are stains; were the metals used they would be considered additions of honour. See Plate LXXXVI. Augmentations are additional charges borne on an escutcheon, a canton, or chief, and given as particular marks of honour. See Plate LXXXVI.

OF THE CHARGES.

Whatsoever is contained in the field, whether it occupy the whole or only a part thereof, is called a charge. All charges are distinguished

distinguished by the names of honourable ordinaries, sub-ordinaries, and common charges.

1. **HONOURABLE ORDINARIES**, the principal charges in heraldry, are made of lines only, which, according to their disposition and form, receive different names.

2. **SUB-ORDINARIES** are ancient heraldic figures, frequently used in coats of arms, and which are distinguished by terms appropriated to each of them.

3. **COMMON CHARGES** are composed of natural, artificial, and even chimerical things; such as planets, creatures, vegetables, instruments, &c.

1. The most judicious armorists admit only of nine honourable ordinaries, viz. The chief; the Pale; the Bend; the Bend Sinister; the Fess; the Bar; the Chevron; the Cross; and the Saltier.

1. The **CHIEF** is an ordinary determined by an horizontal line, which, if it be of any other form but straight, must be expressed. It is placed in the upper part of the escutcheon, and contains in depth the third part of the field. Its diminutive is a fillet, the content of which is not to exceed one-fourth of the chief, and stands in the lowest part thereof. This ordinary is subject to be charged with variety of figures; and may be indented, wavy, nebule, &c. It is peculiar to those who have obtained it by extraordinary merit. The examples in plate LXXXVI. are Or, a chief Gules, and Azure, a chief, invecked, Or.

The **PALE** is an ordinary, consisting of two perpendicular lines drawn from the top to the base of the escutcheon, and contains the third middle-part of the field. Its diminutives are, the pallet, which is the half of the pale; and the endorse, which is the fourth part of a pale. This ordinary and the pallet may receive any charge, but the endorse should not be charged. The example is Gules, a pale Or.

3. The **BEND** is an ordinary formed by two diagonal-lines, drawn from the dexter chief to the sinister base; and contains the fifth part of the field in breadth, if uncharged; but if charged, then the third. Its diminutives are, the bendlet, which is the half of a bend; the cost or cotice, when two of them accompany a bend, which is the fourth part of a bend; and the ribband, the moiety of a cost, or the 8th part of a field. Example, Or, a bend Azure.

The **BEND SINISTER** is of the same breadth as the bend, but drawn the contrary way: this is subdivided into a scrape, which is the half of the bend, and into a bâton, which is the fourth part of the bend, but does not extend itself to the extremities of the field, there being part of it seen at both ends. See Plate LXXXVI. Example, Gules, a bâton argent.

4. The **FESS** is situated in the centre of the shield, and contains in breadth the third part of the escutcheon. See Plate LXXXVII. the example is Azure, a fess Argent.

5. The **BAR** differs from the fess only, as it is but the fifth part of the shield. It is divided into the closet, or a moiety of the bar; and the barulet, or half the closet. When the shield contains a number of bars of metal and colour alternate, of even number, that is called barry of so many pieces, expressing their number.

6. The **CHEVRON**, which represents two rafters of a house well joined together, or a pair of compasses half open, takes up the fifth part of the field with the English, but the French gave it the third. Its diminutives are, The cheveronnel, which contains the half of a chevron; and the couple-close, which is the half of a cheveronnel, that is, its breadth is but the fourth part of a chevron. See Plate LXXXVII. Example, Gules, a cheveron Or.

7. The **CROSS** is an ordinary formed by the meeting of two perpendicular with two horizontal lines in the fess point, where they make four right angles; the lines are not drawn throughout, but discontinued the breadth of the ordinary, which takes up only the fifth part of the field when not charged; but if charged, then the third. It is borne as well engrailed, indented, &c. as plain. The example, Plate LXXXVII. is, Or, a cross Sable. There is a great variety of crosses used in heraldry. The moline is a cross which turns round both ways, at each of the four extremities like a hook. The crosslet is a cross crossed again near the extremities at each end. See Plate LXXXVI. Argent, a crosslet vert.

8. **SALTIER** which is formed by the bend and bend sinister crossing each other in right angles, as the intersecting of the pale and fess forms the cross, contains the fifth part of the field; but if charged, then the third. It may, like the others, be borne engrailed, wavy, &c. as also between charges, or charged with any thing.

See Plate LXXXVII. example, Sable a saltier embattled, counter embattled, Argent.

II. The heraldic figures, called Sub-Ordinaries, or Ordinaries only, which, by reason of their ancient use in arms, are of worthy bearing, viz. The Gyron, Franc-quarter, Canton, Paire, Fret, Pile, Orle, Inescutcheon, Tressure, Annulet, Flanches, Flasques, Voiders, Billet, Lozenge, Guttés, Fusil, Rustré, Mascle, Papilone, and Diaper. See Plate LXXXVII.

The **GYRON** is a triangular figure formed by two lines, one drawn diagonally from one of the four angles to the centre of the shield, and the other is drawn either horizontal or perpendicular, from one of the sides of the shield, meeting the other line at the centre of the field. The figure, Plate LXXXVII. Or, a gyron, Azure. Gyronny is when the field is covered with six, eight, or twelve gyrons in a coat of arms.

The **FRANC-QUARTER** is a square figure, which occupies the upper dexter quarter of the shield. It is but rarely carried as a charge. Example, Or, a quarter Azure.

The **CANTON** is a square part of the escutcheon, somewhat less than the quarter, but without any fixed proportion. It represents the banner that was given to ancient knights bannerets, and, generally speaking, possesses the dexter-chief point of the shield, as in the figure; but should it possess the sinister corner, which is but seldom, it must be blazoned by a canton sinister. It is added to coats of arms of military men as an augmentation of honour. See Plate LXXXVII. Argent, a canton Gules.

The **PAIRLE** is a figure formed by the conjunction of the upper half of the saltier with the under half of the pale.

The **FRET** is a figure representing two little sticks in saltier, with a mascle in the centre interlaced. Fretty is said when the field or bearings are covered with a fret of six, eight, or more pieces, as in Plate LXXXVII. The word fretty may be used without addition, when it is of eight pieces; but if there be less than that number, they must be specified.

The **PILE**, which consists of two lines, terminating in a point, is formed like a wedge, and is borne engrailed, wavy, &c. It issues in general from the chief, and extends towards the base; yet there are some piles borne in bend, and issuing from other parts of the field. The figure, Plate LXXXVII. is Azure, a pile ermine.

The **ORLE** is an ordinary composed of two lines going round the shield, the same as the bordure, but its breadth is but one-half of the latter, and at some distance from the brim of the shield.

The **INESCUTCHEON** is a little escutcheon borne within the shield. That which is fixed on the fess point is called escutcheon of pretence, which is to contain the arms of a wife that is an heiress. The fig. Plate LXXXVII. is ermine, an inescutcheon gules.

The **TRESSURE** is an ordinary commonly supposed to be the half of the breadth of an orle, and is generally borne flowery and counter-flowery, as it is also very often double, and sometimes treble. Example, Argent, a tressure gules.

The **ANNULET**, or **RING**, is a well-known figure, and is frequently to be found in arms through every kingdom in Europe. See Plate LXXXVI.

The **FLANCHES** are formed by two curved lines, or semicircles, being always borne double. Plate LXXXVII. Or, Flanches, gules.

FLAQUES resemble the flanches, except that the circular lines do not go so near the centre of the field.

The **VOIDERS** are by Guillim considered as a sub-ordinate ordinary, and are not unlike the flasques, but they occupy less of the field.

The **BILLET** is an oblong square, twice as long as broad. Some heralds imagine, that they represent bricks for building; others more properly consider them as representing folded paper or letters. See Plate LXXXVI.

The **LOZENGE** is an ordinary of four equal and parallel sides, but not rectangular; two of its opposite angles being acute, and the other two obtuse. Plate LXXXVII. Or, a lozenge azure.

GUTTES, or **DROPS**, are round at bottom, waved on the sides, and terminate at the top in points. Herald's have given them different names according to their different tinctures: thus, if they are yellow, they are called Goutte d'Or; if white, d'Eau; if red, de Sang; if blue, de Larmes; if green, de Vert; if black, de Poix. See Plate LXXXVII. Argent, goutte de sang.

The **FUSIL** is longer than the lozenge, having its upper and lower part more acute and sharp than the other two collateral mid-

dle parts, which acuteness is occasioned by the short distance of the space between the two collateral angles; which space, if the fusil is rightly made, is always shorter than any of the four equal geometrical lines whereof it is composed. See Plate LXXXVII. Gules, a fusil argent.

The **RUSTRE** is a lozenge pierced round in the middle, called by the Germans *rutten*.

The **MASCLE** is pretty much like a lozenge, but voided or perforated through its whole extent, shewing a narrow border. See Plate LXXXVI.

PAPILLONE is an expression used for a field or charge that is covered with figures like the scales of a fish. The proper term for it in English would be scallop-work.

DIAPERING is said of a field or charge, shadowed with flourishing or foliage with a colour a little darker than that on which it is wrought, only serves to embellish the coat. Partitions are such in which there is no tincture from metal, colour, or fur, predominating in them, and are formed of various lines of partition, often causing counterchanging and transmutation. This kind of bearing may be engrailed, &c. See fig. A, Plate LXXXVII. Parted per pale argent and gules. An example of counterchanges is given in fig. B, Argent, a cross per pale, gules and sable. Another example is exhibited in fig. C. Gules on a chevron argent, three bars, gemell's sable. If the fore-mentioned ordinaries have any attributes, that is, if they are engrailed, indented, wavy, &c. they must be distinctly specified, after the same manner as the honourable ordinaries.

III. THE COMMON CHARGES ARE VERY NUMEROUS.

As in all ages men have made use of representations of animals and other symbols to distinguish themselves in war, human ingenuity has been not a little exerted, in multiplying these marks of distinction, by all sorts of figures, some natural, others artificial, and many chimerical; in allusion to the state, quality, or inclination, of the bearer. Hence the sun, moon, stars, comets, meteors, &c. have been introduced to denote glory, grandeur, power, &c. Lions, leopards, tigers, serpents, stags, &c. have been employed to signify courage, strength, prudence, swiftness, &c. War, hunting, music, &c. have furnished lances, swords, pikes, arms, fiddles, &c. Architecture, columns, cheverons, &c.; and the other arts various things that relate to them. Human bodies, or parts of them, as well as clothes, and ornaments, have, for particular intentions, found place in armory. Trees, plants, fruits, and flowers, have also been adopted, to denote the rarities, advantages, and singularities, of different countries. The relation of some creatures, figures, &c. to particular names, has been likewise a very fruitful source of variety in arms. Thus the family of *Corningsby* bears three coney; of *Arundel*, six swallows, from *hirundo*, the Latin for a swallow; of *Urson*, a bear, from the Latin *ursus*; of *Lucie*, three pikes, in Latin *tres lucius pisces*; of *Starkey*, a stork; of *Castleman*, a castle triple-towered; of *Shuttleworth*, three weaver's shuttles, &c. Besides these natural and artificial figures, many chimerical or imaginary ones are used in heraldry, the result of fancy and caprice; such as centaurs, hydras, phenixes, griffons, dragons, &c. This great variety of figures prevents us from comprehending all common charges in a work of this nature; therefore such only are treated of as are most frequently borne in coats of arms. Celestial figures are borne single, upon or between any of the honourable ordinaries, and then three are the usual number. See fig. D, Plate LXXXVII. Diamond, a fess ermine, between three crescents pearl. Fig. E is an example of vegetables used in arms. Vert five fig-leaves in saltier. Of animals the lion is the most honourable; and all bearings of quadrupeds are more honourable than fowls, and fowls than fishes. Fig. F. Or, a lion rampant sable. Fig. G. Gules, a talbot passant, a chief ermine. Fig. H. Ermine, an eagle displayed, gules. Fig. I. Azure, three trouts fretted in triangle argent. These charges have, as well as ordinaries, various attributes or epithets, which express their qualities, positions, and dispositions. Thus the sun is said to be in his glory, eclipsed, &c. The moon, in her complement, increscent, &c. Animals are said to be rampant, passant, &c. Birds have also their denominations, such as close, displayed, &c. Fishes are described to be hauriant, naiant, &c. Lions are termed *lioncels*, if more than two in a field, and eagles *eaglets*. A lion is said to be couchant, when ly-

ing down; and rampant, when standing on his hind-legs, and rearing up his fore-feet, as if climbing. Trees and plants are also said to be trunked, eradicated, fructuated, or raguled, according as they are represented in arms. Artificial figures have different epithets, serving either to express their position, disposition, or make: viz. swords are said to be erect, pommeled, hilted, &c.; arrows, armed, feathered, &c.; towers, covered, embattled, &c.; and so on of all others. Some of these epithets are exemplified in Plate LXXXVII.

OF THE EXTERNAL ORNAMENTS OF ESCUTCHEONS.

The ornaments that accompany or surround escutcheons were introduced to denote the birth, dignity, or office, of the persons to whom the coat of arms appertaineth; which is practised both among the laity and clergy. Those most in use are of ten sorts, viz. Crowns, Coronets, Mitres, Helmets, Mantlings, Chapeaux, Wreaths, Crests, Scrolls, and Supporters.

CROWNS. The first crowns were only diadems, bands, or fillets; afterwards they were composed of branches of trees, and then flowers were added to them. Among the Greeks, the crowns given to those who carried the prize at the Isthmian games, were of pine; at the Olympic, of laurel; and at the Nemean, of smallage. The Romans had various crowns to reward martial exploits and extraordinary services done to the republic; for which see the article **CROWN**.

Examples of some of these **ANCIENT CROWNS** are frequently met with in modern achievements, as 1. The mural crown. 2. The naval or rostral crown. 3. The castense or vallary crown. 4. The civic crown. 5. The radiated crown. 6. The celestial crown, formed like the radiated, with the addition of a star on each ray; is only used upon tomb-stones, monuments, and the like. Others of the ancient crowns are still borne as crests.

But **MODERN CROWNS** are only used as ornaments, which emperors, kings, and independent princes, set on their heads, in great solemnities, to denote their sovereign authority. These are the most in use in heraldry, and are as follows:

The **IMPERIAL CROWN** is made of a circle of gold, adorned with precious stones and pearls, heightened with fleurs-de-lis, bordered and seeded with pearls, raised in the form of a cap voided at the top, like a crescent. From the middle of this cap rises an arched fillet enriched with pearls, and surmounted of a mound, whereon is a cross of pearls. See Plate LXXXVII.

The **CROWN of the KINGS of GREAT BRITAIN**, is a circle of gold, bordered with pearls and precious stones, and heightened up with four crosses pattee and four large fleurs-de-lis alternately; from these rise four arched diadems adorned with pearls, which close under a mound, surmounted of a cross like those at bottom. Mr. Sandford, in his *Genealogical History*, p. 381, remarks, that Edward IV. is the first king of England, who in his seal, or on his coin, is crowned with an arched diadem. See Plate LXXXVII.

The crowns of Spain and Portugal, are a ducal coronet, heightened up with eight arched diadems that support a mound, ensigned with a plain cross. Those of Denmark and Sweden consist of eight arched diadems, rising from a marquis's coronet, which conjoin at the top under a mound ensigned with a cross botone.

The crowns of most other kings of Europe are circles of gold, adorned with precious stones, and heightened up with large trefoils, and closed by four, six, or eight diadems, supporting a mound, surmounted of a cross.

The **Grand Signior** bears over his arms a turban, enriched with pearls and diamonds, under two coronets, the first of which is made of pyramidal points heightened up with large pearls, and the uppermost is surmounted with crescents.

The **Pope** appropriates to himself a Tiara, or long cap of golden cloth, from which hang two pendants embroidered and fringed at the ends, semee of crosses of gold. This cap is inclosed by three marquis's coronets; and has on its top a mound of gold.

CORONETS. The **Coronet of the PRINCE of WALES**, or eldest son of the king of Great Britain was anciently a circle of gold set round with four crosses-pattee, and as many fleurs-de-lis alternately; but since the restoration, it has been closed with one arch only, adorned with pearls, and surmounted of a mound and cross, and bordered with ermine like the king's. See Plate LXXXVII. But besides the coronet, his royal highness has another distinguish-

ing mark of honour, peculiar to himself, viz. A plume of three ostrich-feathers, with a coronet of the ancient princes of Wales. Under it in a scroll, is this motto, *Ich Dien*, which in the German or old Saxon language signifies, *I serve*. This device was at first taken by Edward prince of Wales, commonly called the Black Prince, after the battle of Cressy, in 1346, where having with his own hand killed John king of Bohemia, he took from his head such a plume, and put it on his own.

The coronet of all the PRINCES, immediate sons and brothers of the kings of Great Britain, is a circle of gold, bordered with ermine, heightened up with four fleurs-de-lis, and as many crosses-patee alternate. The particular and distinguished form of such coronets as are appropriated to princes of the blood-royal, is described and settled in a grant of the 13th of Charles II.

The coronet of the PRINCESSES of Great Britain is a circle of gold, bordered with ermine, and heightened up with crosses-patee, fleurs-de-lis, and strawberry leaves alternate.

A DUKE's coronet is a circle of gold bordered with ermine, enriched with precious stones and pearls, and set round with eight large strawberry or parsley leaves.

A MARQUIS's coronet is a circle of gold, bordered with ermine, set round with four strawberry leaves, and as many pearls on pyramidal points equal height, alternate.

An EARL's coronet is a circle of gold, bordered with ermine, heightened up with eight pyramidal points or rays, on the tops of which are as many large pearls, and are placed alternately with as many strawberry-leaves, but the pearls much higher than the leaves.

A VISCOUNT's coronet differs from the preceding ones as being only a circle of gold bordered with ermine, with large pearls set close together on the rim, without any limited number, which is his prerogative above the baron, who is limited.

A BARON's coronet, which was granted by king Charles II. is formed with six pearls set at equal distances on a gold-circle, bordered with ermine, four of which only are seen on engravings, paintings, &c. to shew he is inferior to the viscount.

The eldest sons of peers, above the degree of a baron, bear their father's arms and supporters with a label, and use the coronet appertaining to their father's second title; and all the younger sons bear their arms with proper differences, but use no coronets. See Plate LXXXVII.

MITRES. The archbishops and bishops of England and Ireland place a mitre over their coats of arms. It is a round cap pointed and cleft at the top, from which hang two pendants fringed at both ends; with this difference, that the bishop's mitre is only surrounded with a fillet of gold, set with precious stones; whereas the archbishop's issues out of a ducal coronet. See Plate LXXXVIII. This ornament, with other ecclesiastical garments, is still worn by the archbishops and bishops of the church of Rome, whenever they officiate with solemnity; but it is never used in England, except on coats of arms.

HELMETS. The helmet was formerly worn as a defensive weapon, to cover the bearer's head and face; and is now placed over a coat of arms as its chief ornament, and the true mark of gentility. The helmets of sovereigns were of burnished gold damasked; those of princes and lords, of silver figured with gold; those of knights, of steel adorned with silver; and those of private gentlemen, of polished steel. As to their form; Those of the kings and royal family, and noblemen, of Great Britain, are open-faced and grated, and the number of bars serves to distinguish the bearer's quality; that is, the helmet appropriated to the dukes and marquises is different from the king's, by having a bar exactly in the middle, and two on each side, making but five bars in all, whereas the king's helmet has six bars, viz. three on each side. The other grated helmet with four bars is common to all degrees of peerage under a marquis. The open-faced helmet without bars denotes baronets and knights. The close helmet is for all esquires and gentlemen. Their position is also looked upon as a mark of distinction. The grated helmet in front belongs to sovereign princes. The grated helmet in profile is common to all degrees of peerage. The helmet standing direct without bars, and the beaver a little open, denote baronets and knights. Lastly, the side-standing helmet, with beaver close, is the way of wearing it amongst esquires and gentlemen. See Plate LXXXVIII.

MANTINGS. These are pieces of cloth jagged or cut into

flowers and leaves, which serve as an ornament for escutcheons. They were the ancient coverings of helmets, to preserve them, or the bearer, from the injuries of the weather; as also to prevent the ill consequences of their too much dazzling the eye in action. But Guillim very judiciously observes, that their shape must have undergone a great alteration since they have been out of use, and therefore might more properly be termed flourishings than mantlings.

CHAPEAU. This is an ancient hat, or rather cap, of dignity, worn by dukes, generally scarlet-coloured velvet on the outside, lined and turned up with fur; of late frequently to be met with above an helmet, instead of a wreath, under gentlemen's and noblemen's crests. See Plate LXXXVIII.

WREATH. This is a kind of roll, made of two skains of silk of different colours twisted together, which ancient knights wore as a head-dress when equipped for tournaments. The colours of the silk are always taken from the principal metal and colour contained in the bearer's coat of arms. They are still accounted one of the lesser ornaments of escutcheons, and are placed between the helmet and the crest.

The CREST is the highest part of the ornaments of a coat of arms. It is called crest, from the Latin word *crista*, which signifies comb or tuft, such as many birds have upon their heads, as the peacock, pheasant, &c. in allusion to the place on which it is fixed. Crests were formerly great marks of honour, because they were only worn by heroes of great valour, or by such as were advanced to some superior military command, that they might be the better distinguished in an engagement, and thereby rally their men if dispersed; but they are at present considered as mere ornaments.

The SCROLL. The scroll is the ornament placed sometimes above the crest, but most usually below the shield and supporters; containing a motto, or short sentence, alluding thereto, or to the bearings; or to the bearer's name, as in the two following instances. The motto of the noble earl of Cholmondeley is, *Cassid tutissima virtus*; i. e. "Virtue is the safest helmet;" on account of the helmet in the coat of arms. The motto of the right hon. lord Fortescue is, *Forte scutum salus ducum*; i. e. "A strong shield is the safety of the commanders;" alluding to the name of that ancient family. Sometimes it has reference to neither, but expresses something divine or heroic; as that of the earl of Scarborough, which is, *Murus areus conscientia sana*; i. e. "A good conscience is a wall of brass." Others are enigmatical; as that of the royal achievement, which is, *Dieu et mon droit*, i. e. "God and my right;" introduced by Edward III. in 1340.

SUPPORTERS. These are figures standing on the scroll, and placed at the side of the escutcheon; they are so called, because they seem to support or hold up the shield. The rise of supporters is, by F. Menestrier, traced up to ancient tournaments, wherein the knights caused their shields to be carried by servants or pages under the disguise of lions, bears, griffons, blackmoors, &c. who also held and guarded the escutcheons, which the knights were obliged to expose to public view for some time before the lists were opened. Sir George Mackenzie, who dissents from this opinion, says, in his "Treatise on the Science of Heraldry," chap. xxxi. p. 93. "That the first origin and use of them was from the custom which ever was, and is, of leading such as are invested with any great honour to the prince who confers it: thus, when a man is created a duke, marquis, or knight of the garter, or any other order, he is supported by, and led to the prince betwixt two of the quality, and so receives from him the symbols of that honour; and in remembrance of that solemnity, his arms are thereafter supported by any two creatures he chooses." Supporters have formerly been taken from such animals or birds as are borne in the shields, and sometimes they have been chosen as bearing some allusion to the names of those whose arms they are made to support. The supporters of the arms of Great Britain, since king James the First's accession to the throne, are a Lion rampant guardant crowned Or, on the dexter side, and an Unicorn Argent, crowned, armed, unguled, maned and gorged with an antique Crown, to which a chain is affixed, all Or, on the sinister. See Plate LXXXVIII. Bearing coats of arms supported, is, according to the heraldic rules of England, the prerogative, 1st, Of those called nobles majores, viz. dukes, marquises, earls, viscounts, and

barons: 2d, Of all knights of the garter, though they should be under the degree of barons; and 3d, Of knights of the Bath, who both receive on their creation a grant of supporters. And, lastly, of such knights as the king chooses to bestow this honour upon; as in the instance of Sir Andrew Fountain, who was knighted by Philip earl of Pembroke, when lord lieutenant of Ireland, Fountain being then secretary; and on his return to England, King William granted him supporters to his arms, viz. two Griffons, Gules, and Or. In Scotland, all the chiefs of clans or names have the privilege of claiming supporters; also the barons.

RULES OF BLAZONING.

I. The first and most general rule is, to express heraldic distinctions in proper terms, so as not to omit any thing that ought to be specified, and at the same time to be clear and concise without tautology.

II. Begin with the tincture of the field, and then proceed to the principal charges which possess the most honourable place in the shield, such as Fess, Chevron, &c. always naming that charge first which lies next and immediately upon the field.

III. After naming the tincture of the field, the honourable ordinaries, or other principal figures, specify their attributes, and afterwards their metal or colour.

IV. When an honourable ordinary, or some one figure, is placed upon another, whether it be a Fess, Chevron, Cross, &c. it is always to be named after the ordinary or figure over which it is placed, with one of these expressions, sur tout, or over all.

V. In blazoning such ordinaries as are plain, the bare mention of them is sufficient; but if an ordinary should be made of any of the crooked lines mentioned above, its form must be specified; that is, whether it be Engrailed, Wavy, &c.

VI. When a principal figure possesses the centre of the field, its position is not to be expressed: or (which amounts to the same thing) when a bearing is named, without specifying the point where it is placed, then it is understood to possess the middle of the shield.

VII. The number of the points of mullets or stars must be specified when more than five; and also if a mullet or any other charge be pierced, it must be mentioned as such, to distinguish it from what is plain.

VIII. When a ray of the sun, or other single figure, is borne in any other part of the escutcheon than the centre, the point it issues from must be named.

IX. The natural colour of trees, plants, fruits, birds, &c. is no otherwise to be expressed in blazoning but by the word proper; but if discoloured, that is, if they differ from their natural colour it must be particularized.

X. When three figures are in a field, and their position is not mentioned in the blazoning, they are always understood to be placed two above, and one below.

XI. When there are many figures of the same species borne in a coat of arms, their number must be observed as they stand, and distinctly expressed.

There are other positions called irregular; as for example, when three figures which are naturally placed two and one, are disposed one and two, &c. It must also be observed, that when the field is strewn with the same figures, this is expressed by the word semee; but if the figures strewn on the field are whole ones, it must be denoted by the words sans nombre; whereas, if part of them is cut off at the extremities of the escutcheon, the word semee or semi is then to be used.

We shall add a few examples to illustrate these rules, and for other examples refer the reader to the different works on this subject.

Plate LXXXVII. fig. K, Or, on a chief gules, three plates. Fig. L, Argent, three torteauxes in chief. Fig. M, Argent, a fess, in chief three lozenges sable. Fig. N, Ermine, on a chevron engrailed azure, three stars argent. Fig. O, Or, a lion passant sable, in chief three pales of the second. Fig. P, Azure, a tortoise erect, Argent. Fig. Q, Argent, a dragon's head erased vert, holding in his mouth a sinister hand, couped at the wrist, gules. Fig. R, Sable, a pile argent, surmounted of a chevron gules. Fig. S, Quarterly, first and fourth azure, a pale argent; second and third gules, a bend argent.

OF MARSHALLING COATS OF ARMS.

By marshalling coats of arms, is to be understood the art of disposing divers of them in one escutcheon, and of distributing their contingent ornaments in proper places. Various causes may occasion arms to be thus conjoined.

I. When the coats of arms of a married couple, descended of distinct families, are to be put together in one escutcheon, the field of their respective arms is conjoined pale-ways, and blazoned parted per Pale, Baron and Femme, two coats; first, &c. In which case the baron's arms are always to be placed on the dexter side, and the femme's arms on the sinister side. See Plate LXXXVIII.

II. If a widower marry again, his late and present wife's arms are, according to G. Leigh, "to be both placed on the sinister side, in the escutcheon with his own, and parted per Pale. The first wife's coat shall stand on the Chief, and the second on the Base; or he may set them both in Pale with his own, the first wife's coat next to himself, and his second outermost. If he should marry a third wife, then the two first matches shall stand on the Chief, and the third shall have the whole Base. And if he take a fourth wife, she must participate one-half of the Base with the third wife, and so will they seem to be so many coats quartered." But these forms of impaling are meant of hereditary coats, whereby the husband stands in expectation of having the hereditary possessions of his wife united to his patrimony. If a man marry a widow, he marshals her maiden arms only. See Plate LXXXVIII.

III. In the arms of femmes joined to the paternal coat of the baron, the proper differences by which they were borne by the fathers of such women must be inserted.

IV. If a coat of arms that has a Bordure be impaled with another, as by marriage, then the Bordure must be wholly omitted in the side of the arms next the centre.

V. The person who marries an heiress, instead of impaling his arms with those of his wife, is to bear them in an escutcheon placed in the centre of his shield, and which, on account of its shewing forth his pretension to her estate, is called an escutcheon of pretence, and is blazoned sur-tout, i. e. over all. But the children are to bear the hereditary coat of arms of their father and mother quarterly, which denotes a fixed inheritance, and to transmit them to posterity. The first and fourth quarters generally contain the father's arms, and the second and third the mother's; unless the heirs should derive not only their estate, but also their title and dignity, from their mother.

VI. If a maiden or dowager lady of quality marry a commoner, or a nobleman inferior to her rank, their coats of arms may be set beside one another in two separate escutcheons, upon one mantle or drapery, and the lady's arms ornamented according to her title. See Plate LXXXVIII.

VII. Archbishops and bishops impale their arms differently from the fore-mentioned coats, in giving the place of honour, that is, the dexter side, to the arms of their dignity, as it is expressed in Plate LXXXVIII.; which represents the coat of arms of an archbishop of Canterbury, and a bishop of an English see. These prelates thus bear their arms parted per Pale, to denote their being joined to their cathedral-church in a sort of spiritual marriage.

With respect to such armorial ensigns as the sovereign thinks fit to augment a coat of arms with, they may be marshalled various ways, as may be seen by the arms of his grace the duke of Rutland, and many others. When coats of arms are marshalled in such a manner, that no probable reason can be given why they are so conjoined, they must be left to heralds to explain.

OF THE ORDER OF KNIGHTHOOD, &c.

To the augmentations above-mentioned may be added,

1. The Baronet's mark of distinction, or the arms of the province of Ulster in Ireland, granted and made hereditary in the male-line by king James I. who erected this dignity on the 22d of May 1611, in the seventh year of his reign, in order to propagate a plantation in the fore-mentioned province. This mark is Argent, a sinister Hand couped at the Wrist, and erected Gules; which may be borne either in a canton, or in an escutcheon, as will best suit the figures of the arms. See Plate LXXXVIII.

Partition Lines.

Shields or Escutcheons.

Bordures

Chiefs

Pale

Bend

Bâton

2. The ancient and respectable badge of the most noble Order of the Garter, instituted by king Edward III. 1349, in the 27th year of his reign. This honourable augmentation is a deep blue garter, surrounding the arms of such knights, and inscribed with this motto, "Honi soit qui mal y pense." See Plate LXXXVIII.

The arms of those who are knights of the orders of the Bath, of the Thistle, or of St. Patrick, are marshalled in the same manner, with this difference only, that the colour and motto accord with the order to which it belongs. Thus the motto "Quis separabit 1783" on the light blue ribbon of the order, surrounds the escutcheon of a knight of St. Patrick. "Nemo me impune lacessit," on a green ribband, distinguishes a knight of the Thistle; and, "Tria juncta in uno," on red, a knight of the Bath. None of these orders of Knighthood are hereditary; but the honours of a Baronet of Ulster, and of a Baronet of Nova Scotia (created by patent in 1602,) descend to the heirs male. With regard to the emblazoning of the wife's arms in the case of the husband being noble, or a knight of the Garter, of the Bath, &c. or where, on

the other hand, the wife is noble in her own right, and the husband a commoner, these will be found exemplified in Plate LXXXVIII. For representations of the Badges of the several Orders of Knighthood. See Plate LXXXVIII.

HATCHMENTS. These are funeral-escutcheons, whereby may be known, after any person's decease, what rank he or she held when living; and if it be a gentleman's hatchment, whether he was a bachelor, married man, or widower, with the like distinctions for gentlewomen. The hatchment is usually affixed to the fronts of houses, when any of the nobility or gentry die. 1. The arms, if the deceased be a private gentleman, are parted per Pale with those of his wife. The ground without the escutcheon being black denotes the man to be dead; and the ground on the sinister side being white signifies that the wife is living; which is represented on Plate LXXXIX. with some other varieties of hatchments.

For further information on the subject of heraldry see the articles **ARMS, BLAZONING, PRECEDENCY,** and the several terms of **HERALDRY.**

HERAULT, a river of France, which rises among the Sevennes mountains, and falls into the gulf of Lyons, below Agde.

HERAULT, a department of France, so named from the river, bounded on the N. by those of Tarn and Aveyron. It comprehends part of the late province of Languedoc. Montpellier is the capital.

HERB, [*herba*, Lat.] in botany, is used by Linnæus, to denominate that portion of every vegetable which arises from the root, and is terminated by the fructification. It comprehends, 1. The trunk, stalk, or stem. 2. The leaves. 3. Those minute external parts called by him the fulcra or supports of plants. 4. The buds, or, as he also terms them, the winter-quarters of the future vegetable. See **BOTANY.**

HERB BENNET. See **GEUM.**

HERB CHRISTOPHER. See **ACTEA.**

HERB GERARD. See **ÆGOPIDIUM.**

HERBACEOUS PLANTS are those which have succulent stems or stalks that lie down to the ground every year. Of herbaceous plants, those are annual which perish stem and root every year; biennial, which subsist by the roots two years; perennial which are perpetuated by their roots for a series of years, a new stem being produced every spring.

HERBAGE, in law, signifies the pasture provided by nature for the food of cattle; also the liberty to feed cattle in the forest, or in another person's ground.

HERBAL, [*herbarium*, Lat.] generally speaking, signifies a book, containing a methodical arrangement of the classes, genera, species, and varieties, of plants, together with an account of their properties. It is also applied to a hortus siccus, or dry garden; an appellation given to a collection of specimens of plants carefully dried and preserved. See **HORTUS SICCUS.**

HERBORN, a town in Westphalia, 3 miles S. S. E. of Dillenburg.

HERCULANEUM, an ancient city of Campania in Italy, which was destroyed by an eruption of Vesuvius in the first year of the emperor Titus, or the 79th of the Christian era, and lately rendered famous on account of the curious monuments of antiquity discovered in its ruins; an account of which has been published by order of the king of Naples, in a work of six volumes folio. The epocha of the foundation of Herculanum is unknown. Dionysius Halicarnassensis conjectures that it may be referred to 60 years before the war of Troy, or about B. C. 1242; and therefore that it lasted about 1400 years. The thickness of the heap of lava, by which the city was overwhelmed, has been much increased by fiery streams vomited since that catastrophe; and now forms a mass 24 feet deep of dark grey stone, which is easily broken to pieces. By its non-adhesion to foreign bodies, marbles and bronzes are preserved in it as in a case made to fit them, and exact moulds of the faces and limbs of statues are frequently found in this substance. The precise situation of this subterraneous city was not known till 1713, when it was accidentally discovered by

some labourers, who, in digging a well struck, upon a statue on the benches of the theatre. Many others were afterwards dug out and sent to France by the prince of Elbœuf. But little progress was made in the excavations, till Charles infant of Spain ascended the Neapolitan throne, by whose unwearied efforts and liberality a very considerable part of Herculanum has been explored, and such treasures of antiquity drawn out as form the most curious museum in the world. It being too arduous a task to attempt removing the covering, the king contented himself with cutting galleries to the principal buildings, and causing the extent of one or two of them to be cleared. Of these the theatre is the most considerable. On a ballustrade which divided the orchestra from the stage was found a row of statues; and, on each side of the pulpitum, the equestrian figure of a person of the Nonian family. They are now placed under porticos of the palace; and from the great rarity of equestrian statues in marble would be very valuable objects, were the workmanship even less excellent than it is: one of them in particular is a very fine piece of sculpture. Since the king of Spain left Naples, the digging has been continued, but with less spirit and expenditure: indeed the collection of curiosities brought out of Herculanum and Pompeii is already so considerable, that a relaxation of zeal and activity becomes excusable. They consist of statues, busts, altars, inscriptions, and other ornamental appendages of opulence and luxury; and also an entire assortment of the domestic, musical, and chiralurgical instruments used by the ancients; tripods of elegant form and exquisite execution, lamps in endless variety, vases and basons of noble dimensions, chandeliers of the most beautiful shapes, pateras, and other appurtenances of sacrifice, looking-glasses of polished metal, coloured glass, so hard, clear, and well stained, as to appear emeralds, sapphires, and other precious stones; a kitchen completely fitted up with copper-pans lined with silver, kettles, cisterns for heating water, and every utensil necessary for culinary purposes; specimens of various sorts of combustibles, retaining their form though burnt to a cinder; corn, bread, fish, oil, wine, and flour: a lady's toilet, fully furnished with combs, thimbles, rings, paint, ear-rings, &c. Among the statues, which are numerous, a Mercury and a sleeping faun are most admired by connoisseurs. A large parcel of M.SS. was found among the ruins. Hopes were entertained, that many works of the ancients were now going to be restored to light, and that a new mine of science was on the point of being opened. But the difficulty of unrolling the burnt parchment, of pasting the fragments on a flat surface, and of decyphering the obscure letters, have proved such obstacles, that very little progress has been made in the work. A priest invented a method of proceeding; but it would require the joint labours of many learned men to carry on so nice and tedious an operation with success. The plan is dropped; and the M.SS. now lie in dusty heaps, as useless to the learned world as they had been for the preceding 17 centuries.

HERCULES, in fabulous history, a most renowned Grecian hero, who after death was ranked among the gods, and received divine

divine honours. According to the ancients, there were many persons of this name. Diodorus mentions 3, Cicero 6, and some authors no less than 43. Of all these, one generally called the Theban Hercules, is the most celebrated; and to him the actions of the others have been attributed. He is reported to have been the son of Jupiter by Alcmena. In his 18th year he delivered the neighbourhood of mount Citharon from a huge lion which preyed on the flocks of Amphitryon, and laid waste the adjacent country. He went to the court of Thespius king of Thespiis, who shared in the general calamity, by whom he was hospitably entertained for 50 days; but he made a bad return, for the king's 50 daughters became mothers by him during his stay at Thespiis, and some say in one night. He next delivered his country from the tribute of 100 oxen, annually paid to Erginus. Such public services became universally known; and Creon king of Thebes, rewarded his patriotic deeds by giving him his daughter in marriage, and entrusting him with the government. Eurystheus, the son of Amphitryon, having succeeded his father, became jealous of Hercules; and lest he should deprive him of his crown, left no means untried to get rid of him. On this Hercules consulted the oracle; but being answered that it was the pleasure of the gods that he should serve Eurystheus 12 years, he fell in a deep melancholy which at last ended in a furious madness; during which, among other desperate actions, he put away his wife, Megara, and murdered all the children he had by her. As an expiation of this crime, the king imposed upon him 12 labours surpassing the power of all other mortals to accomplish, which nevertheless our hero performed with ease, the favours of the gods having indeed completely armed him. He had received a coat of armour and helmet from Minerva, a sword from Mercury, a horse from Neptune, a shield from Jupiter, a bow and arrows from Apollo, and from Vulcan a golden cuirass and brazen buskin, with a celebrated club of brass. His first labour was the killing of a lion in Nemea, a wood of Achaia; whose hide was proof against any weapon, so that he was forced to seize him by the throat and strangle him. He carried the dead beast on his shoulders to Mycenæ, and ever after clothed himself with the skin. The second labour was to destroy the Lernaean hydra, which had seven heads according to Apollodorus, 50 according to Simonides, and 100 according to Diodorus. This monster he first attacked with his arrows; but soon after by means of his heavy club he destroyed the heads of his enemy. This, however, was productive of no advantage; for as soon as one head was beaten to pieces by the club, two sprang up; and the labour of Hercules would have remained unfinished, had he not commanded his friend Iolaus to burn with a hot iron the root of the head which he had crushed to pieces. This succeeded; and Hercules became victorious, opened the belly of the monster, and dipped his arrows in the gall to render the wounds they should give incurable. He was ordered in his third labour to bring alive and unhurt into the presence of Eurystheus a stag, famous for its incredible swiftness, its golden horns, and brazen feet. This celebrated animal frequented the neighbourhood of Cnoe; and Hercules was employed for a whole year in pursuing it: at last he caught it in a trap, or when tired. The fourth labour was to bring alive to Eurystheus a wild boar which ravaged the neighbourhood of Erymanthus. In this expedition he destroyed the centaurs, and caught the boar by closely pursuing him through the deep snow. In his fifth labour Hercules was ordered to clean the stables of Augeas, where 3000 oxen had been confined for many years. For his sixth labour he was ordered to kill the carnivorous birds which ravaged the country near the lake Stympthalis in Arcadia. In his seventh labour he brought alive into Peloponnesus a prodigious wild bull which laid waste the island of Crete. In his eighth labour he was employed in obtaining the mares of Diomedes, king of Thrace, which fed upon human flesh. For his ninth labour, he was commanded to obtain the girdle of the queen of the Amazons. In his tenth labour he killed the monster Geryon king of Gades, and brought to Argos his numerous flocks which fed upon human flesh. His eleventh labour was the carrying away of the Hesperian golden apples kept by a dragon. The twelfth and last, and most dangerous of his labours, was to bring up to the earth the three-headed dog Cerberus. Descending into hell by a cave on mount Tarnarus, he was permitted by Pluto to carry away his friends Theseus and Pirithous, who were condemned to punishment in hell,

and Cerberus also was granted to his prayers, provided he made use of no arms to drag him away. Hercules carried him back to hell after he had brought him before Eurystheus. Many other exploits were performed by Hercules. He accompanied the Argonauts to Colchis before he delivered himself up to Eurystheus. He assisted the gods in their wars against the giants, and it was through him that Jupiter obtained the victory. He conquered Laomedon, and pillaged Troy. When Iole, the daughter of Eurystus king of Ecbalia, of whom he was deeply enamoured, was refused to his entreaties, he fell into a second fit of insanity, and murdered Iphitus, the only one of the sons of Eurystus who favoured his addresses to Iole. He was afterwards purified of the murder, and his insanity ceased; but he was visited by a disorder which obliged him to apply to the oracle of Delphi for relief. The coldness with which the Pythia received him irritated him, and he resolved to plunder Apollo's temple, and carry away the sacred tripod. Apollo opposed him, and a severe conflict was begun, which nothing but the interference of Jupiter with his thunderbolts could have settled. He was upon this told by the oracle that he must be sold as a slave, and remain three years in the most abject servitude to recover from his disorder. He complied, and Mercury by order of Jupiter, conducted him to Omphale, queen of Lydia, to whom he was sold as a slave. Here he cleared all the country from robbers; and Omphale, astonished at the greatness of his exploits, married him. Hercules had Agelaus and Lamon by Omphale, from whom Cressus king of Lydia was descended. Many other wondrous exploits are said to have been achieved by him: by the direction of the oracle he raised a burning pile on Mount Eta, where he finished his life. His friends raised an altar where the burning pile had stood; and Menætius the son of Actor sacrificed a bull, a wild boar, and a goat; and enjoined the people of Opus to observe these ceremonies annually. His worship soon became as universal as his fame; and Juno, forgetting her resentment, gave him her daughter Hebe in marriage. Hercules has many surnames, from the places where his worship was established, and from the labours he had achieved. His temples were numerous and magnificent, and his divinity revered. No dogs or flies entered his temple at Rome: and that of Gades, according to Strabo, was always forbidden to women and pigs. The Phenicians offered quails on his altars; and as he was supposed to preside over dreams, the sick and infirm were sent to sleep in his temples, that they might receive in their dreams the agreeable presages of their approaching recovery. The white poplar was particularly dedicated to his service. None even of the twelve great gods of antiquity have so many ancient monuments as Hercules. The famous statue of Hercules, in the Farnese palace at Rome, is well known to the connoisseurs. It represents him resting after the last of his twelve labours above recited, leaning on his club, and holding the apples of the Hesperides in his hand. HERCULES, in astronomy, a very large constellation of the northern hemisphere. See ASTRONOMY.

HERCULES'S PILLARS, in ancient geography, two lofty mountains, situated one on one of the most southern extremities of Spain, and the other on the opposite part of Africa. They were called Abyla and Calpe; (see these articles;) were reckoned the boundaries of the labours of Hercules; and were fabled to have been joined together till they were severed by that hero, and a communication opened between the Mediterranean and Atlantic.

HEREDITAMENTS, [*heredrum*, Lat.] all such things immoveable, whether corporeal or incorporeal, as a man may leave to his heirs, by way of inheritance; or not being otherwise devised, do naturally descend to him who is next heir of blood, and fall not within the compass of an executor or administrator, as chattels do. It is a word of large extent, and much used in conveyances; for by the grant of hereditaments, isles, seignories, manors, houses, and lands of all sorts, charters, rents, services, advowsons, commons, and whatever may be inherited, will pass. Co. Lit. 6. Hereditaments are of two kinds, corporeal and incorporeal. Corporeal hereditaments consist wholly of substantial and permanent objects, all which may be comprehended under the general denomination of land only: for land comprehends in its legal signification any ground, soil, or earth, whatsoever, as arable, meadows, pastures, woods, moors, waters, marshes, furzes, and heath. 1 Inst. 4. Incorporeal hereditaments are not the object of sensation, neither can they be seen or handled, are creatures of
the

the mind, and exist only in contemplation: they are principally of ten sorts, viz. advowsons, tithes, commons, ways, offices, dignities, franchises, corrolies or presents, and rents. Black.

HEREDITARY, [*hereditarius*, Lat.] possessed or claimed by right of inheritance; descending by inheritance.

HEREDITARY is also figuratively applied to good or ill qualities, either of body or mind, supposed to be transmitted from father to son: thus we say, virtue and piety are hereditary qualities in such a family; that in Italy the hatred of families is hereditary; and that the gout, king's evil, madness, &c. are hereditary diseases.

HEREDITAS JACENS, in Scots law. An estate is said to be in hereditate jacente, after the death of the proprietor till the entry of the heir.

HEREFORD, the capital of Herefordshire, 30 miles N. W. of Gloucester, and 130 W. N. W. of London. Lon. 2. 35. W. Lat. 52. 4. N.

HEREFORDSHIRE, a county of England, bounded on the E. by Gloucester, and Worcestershires, on the W. by Radnor and Brecknockshires, on the N. by Shropshire, and on the S. by Monmouthshire. It extends 35 miles from N. to S. and 47 from E. to W. It is divided into 11 hundreds; contains one city, eight market-towns, 176 parishes. Apples grow in greater abundance here than in any other county, being plentiful even in the hedges. Of these are various kinds; the most celebrated is the redstreak, which is peculiar to this county.

HEREGOVINZA, a territory of European Turkey, in Bosnia, near Dalmatia.

HERESIARCH, [*heresiarche*, French; *ἀρχηγός*,] a leader in heresy; the head of a herd of heretics.

HERESY, [*heresie*, Fr. *hæresis*, Lat. *hæresis*,] a denial of some of the essential doctrines of Christianity, publicly and obstinately avowed; being defined, "sententia rerum divinarum humano sensu excogitata, palam docta et pertinaciter defensa." And here it must be acknowledged, that particular modes of belief, or unbelief, not tending to overturn Christianity, or to sap the foundations of morality, are by no means the object of coercion by the civil magistrate. What doctrines shall therefore be adjudged heresy, was left by our old constitution to the determination of the ecclesiastical judge; who had herein a most arbitrary latitude allowed him. For the general definition of an heretic given by Lyndewode, extends to the smallest deviations from the doctrines of the holy church: "hæreticus est qui dubitat de fide catholica, et qui negligit servare ea, quæ Romana ecclesia statuit, seu servare decreverat." Or, as the statute 2 Hen. IV. c. 15, expresses it in English, "teachers of erroneous opinions, contrary to the faith and blessed determination of the holy church." Very contrary this to the usage of the first general councils, which defined all heretical doctrines with the utmost precision and exactness. And what ought to have alleviated the punishment, the uncertainty of the crime, seems to have enhanced it in those days of blind zeal and pious cruelty. The sanctimonious hypocrisy of the canonists, indeed, went at first no farther than enjoining penance, excommunication, and ecclesiastical deprivation, for heresy; but afterwards they proceeded boldly to imprisonment by the ordinary, and confiscation of goods in pious uses. But in the mean time they had prevailed upon the weakness of bigotted princes to make the civil power subservient to their purposes, by making heresy not only a temporal, but even a capital offence: the Romish ecclesiastics determining, without appeal, whatever they pleased, to be heresy, and shifting off to the secular arm the odium and drudgery of executions; with which they pretended to be too tender and delicate to intermeddle. Nay, they affected to intercede, on behalf of the convicted heretic, ut citra mortis periculum sententiæ circa eum moderetur: well knowing that at the same time they were delivering the unhappy victim to certain death. See **ACT OF FAITH**. Christianity being thus deformed by the demon of persecution upon the continent, our own island could not escape its scourge. Accordingly we find a writ de hæretico comburendo, i. e. of burning the heretic. But the king might pardon the convict by issuing no process against him; the writ de hæretico comburendo being not a writ of course, but issuing only by the special direction of the king in council. In the reign of Henry IV. when the eyes of the Christian world began to open, and the seeds of the Protestant religion under the opprobrious name of Lollardy took root in this kingdom; the clergy,

taking advantage from the king's dubious title to demand an increase of their own power, obtained an act of parliament, which sharpened the edge of persecution to its utmost keenness. See **HÆRETICO COMBURENDO**. By stat. 2. Hen. V. c. 7, Lollardy was also made a temporal offence, and indictable in the king's courts; which did not thereby gain an exclusive, but only a concurrent, jurisdiction with the bishop's consistory. Afterwards, when the reformation began to advance, the power of the ecclesiastics was somewhat moderated; for though what heresy is was not then precisely defined, yet we are told in some points what it is not; the statute 25 Henry VIII. c. 14, declaring that offences against the see of Rome are not heresy; and the ordinary being thereby restrained from proceeding in any case upon mere suspicion; 7. c. unless the party be accused by two credible witnesses, or an indictment of heresy be first previously found in the king's courts of common law. And yet the spirit of persecution was not abated, but only diverted into a lay-channel. For in the reign of Henry VIII, and in the two succeeding reigns, several severe laws were made, and repealed by turns till the reign of Queen Elizabeth; when the reformation was finally established with temper and decency, unsullied with party-rancour, or personal resentment. By stat. 1 Eliz. c. 1, all former statutes relating to heresy are repealed, which leaves the jurisdiction of heresy as it stood at common law; viz. as to the infliction of common censures, in the ecclesiastical courts; and in case of burning the heretic, in the provincial synod only. But the principal point now gained was, that by this statute a boundary is for the first time set to what shall be accounted heresy; nothing for the future being to be so determined, but only such tenets, which have been heretofore so declared, 1. by the words of the canonical scriptures; 2. by the first four general councils, or such others as have only used the words of the holy scriptures; or, 3. which shall hereafter be so declared by the parliament, with the assent of the clergy in convocation. Thus was heresy reduced to a greater certainty than before; though it might not have been the worse to have defined it in terms still more precise and particular: as a man continued still liable to be burnt, for what perhaps he did not understand to be heresy, till the ecclesiastical judge so interpreted the words of the canonical scriptures. For the writ de hæretico comburendo remained still in force, till it was totally abolished, and heresy again subjected only to ecclesiastical correction, pro salute anime, by stat. 29 Car. II. c. 9; when, in one and the same reign, our lands were delivered from the slavery of military tenures; our bodies from arbitrary imprisonment by the habeas corpus act; and our minds from the tyranny of superstitious bigotry, by demolishing this last badge of persecution in the English law. Every thing is now less exceptionable, with respect to the spiritual cognizance, and spiritual punishment, of heresy: unless perhaps that the crime ought to be more strictly defined, and no prosecution permitted, even in the ecclesiastical courts, till the tenets in question are by proper authority previously declared to be heretical. Under these restrictions, some think it necessary for the support of the national religion, that the officers of the church should have power to censure heretics; yet not to harass them with temporal penalties, much less to exterminate or destroy them. The legislature has indeed thought it proper, that the civil magistrate should interpose, with regard to one species of heresy, very prevalent in modern times; for by stat. 9 and 10 W. III. c. 32, if any person educated in the Christian religion, or professing the same, shall, by writing, printing, teaching, or advised speaking, deny any one of the Persons in the Holy Trinity to be God, or maintain that there are more gods than one, he shall undergo the same penalties and incapacities which were inflicted on apostasy by the same statute.

HERETIC, a general name for all such persons under any religion, but especially the Christian, as profess or teach religious opinions contrary to the established faith; or to what is made the standard of orthodoxy. See **HERESY**.

HERETOCH, among the Anglo-Saxons, signified the same with Dux or duke, denoting the commander of an army.

HERGRUNDT, a town of Upper Hungary, 65 miles N. of Buda.

HERICOUR, a town of France, in the department of Upper Saone, 12 miles S. E. of Lure.

HERIOT, [*hergild*, Saxon,] in law, is a customary tribute of goods and chattels, payable to the lord of the see on the de-

cease of the owner of the land. See **TENURE**. It is of two sorts, viz.

I. HERIOT-CUSTOM, where heriots have been paid time out of mind by custom, after the death of a tenant for life. In some places, there is a customary composition in money, as 10 or 20 shillings in lieu of a heriot, by which the lord and tenant are both bound, if it be an indisputably ancient custom; but a new composition of this sort will not bind the representatives of either party.

II. HERIOT-SERVICE, when a tenant holds by such service to pay heriot at the time of his death; which service is expressed in the deed of feoffment. For this latter the lord shall distrain; and for the other he shall seize, and not distrain. If the lord purchase part of the tenancy, heriot-service is extinguished; but it is not so of heriot-custom.

HERISSON, in fortification, a beam armed with a great number of iron-spikes with their points outwards, and supported by a pivot on which it turns. These serve as a barrier to block up any passage, and are frequently placed before the gates, and more especially the wicket-doors, of a town or fortress, to secure those passages which must be often opened and shut.

HERITABLE RIGHTS, in Scots law, signify all rights affecting lands, houses, &c. or any immovable subject.

HERITAGE, in Scots law, implies lands, houses, and all immovable subjects, in contradistinction to moveables or moveable subjects. It also signifies such immovable property, as a person succeeds to as heir to another, in contradistinction to that which he himself purchases, or acquires otherwise, called conquest.

HERTIERA, a genus of the monœcia monadelphia class and order. Calyx five-toothed; corolla none. Male; anthers ten, without filaments. Female; germ five; drupes with one globular seed. There is one species, a tree of the East-Indies, called the looking-glass-tree.

HERK, a river of Germany, in the late bishopric of Liege.

HERK, a town of France, in the department of Ourte, and late bishopric of Liege, 20 miles N. W. of Maestricht.

HERKEMER, a town and county of New York.

HERMÆA, in antiquity, ancient Greek festivals in honour of Mercury. One of these was celebrated by the Pheneatæa in Arcadia; a second by the Cylleians in Elis; and a third by the Tanagraeans.

HERMAN, PAUL, a famous botanist in the 17th century, born at Hall in Saxony. He practised physic in the isle of Ceylon, and was afterwards professor of botany at Leyden, where he died in 1695. He wrote, 1. A Catalogue of the Plants in the public garden at Leyden. 2. *Cynosura Materie Medicæ*. 3. *Floræ Lugduno Batavæ Flores*. 4. *Paradisus Batavus*: and, 5. *Musæum Zeylanicum*.

HERMANN, JAMES, a learned mathematician of the academy at Berlin, and a member of the academy of sciences at Paris, was born at Basil in the year 1678. He was a great traveller, and for six years was professor of mathematics at Padua. He afterwards went to Muscovy, being invited thither by Peter the Great, in 1724. On his return to Basil, he was made professor of morality and natural law; and died there in 1733, aged 55. He wrote "Responso ad Considerationes circa Principia Calculi differentialis;" "De Phoronomia;" "De nova Accelerationis Lege;" "Disquisitio de Vibrationibus Chordarum Censuram;" "Solutio Problematis de Trajectoriis Curvis inveniendis."

HERMANNIA, in botany, a genus of the pentandria order, and monadelphia class of plants; natural order, Columniferæ. Styles five; capsule five-celled; petals semitubular at the base, oblique. There are twenty-one species. The hermannias are shrubs from two to seven feet in height. Natives of the Cape of Good Hope.

HERMAPHRODITE, a person of both sexes, or who has the parts of generation both of male and female. The term is applied to other animals besides man, and even to plants. The word is a compound of *Ἑρμης*, Mercury, and *Ἀφροδίτη*, Venus; *g. d.* a mixture of Mercury and Venus, *i. e.* of male and female. The Greeks also call hermaphrodites, *ἀνδρόγυνος*, androgyni, *g. d.* men-women. See **ANDROGYNES**. In a paper by Mr. Hunter, in the 69th volume of the Philosophical Transactions, hermaphrodites are divided into natural, and unnatural or monstrous. The first

belongs to the more simple orders of animals, of which there is a much greater number than of the more perfect. The unnatural takes place in every tribe of animals, having distinct sexes, but is more common in some than in others. The human species, he imagines, has the fewest, never having seen them in that species, nor in dogs; but in the horse, sheep, and black cattle, they are very frequent. From Mr. Hunter's account, however, it does not appear that such a creature as a perfect hermaphrodite has ever existed. In most species of animals, the production of hermaphrodites appears to be the effect of chance; but in the black cattle it seems to be an established principle of their propagation. It is a well-known fact, and, as far as has yet been discovered, appears to be universal, that when a cow brings forth two calves, one of them a bull, and the other a cow to appearance, the cow is unfit for propagation, but the bull-calf becomes a very proper bull. The cows are known not to breed; they do not even shew the least inclination for the bull, nor does the bull ever take the least notice of them. Among the country-people in England, this kind of calf is called a free-martin; and this singularity is just as well known among the farmers, as either cow or bull. When they are preserved, it is for the purposes of an ox or spayed heifer; viz. to yoke with the oxen, or fatten for the table. They are much larger than either the bull or the cow, and the horns grow longer and bigger, being very similar to those of an ox. The bellow of a free-martin is similar to that of an ox, and the meat is similar to that of the ox or spayed heifer, viz. much finer in the fibre than either the bull or cow: and they are more susceptible of growing fat with good food. By some they are supposed to exceed the ox and heifer in delicacy of taste, and bear a higher price at market; this, however, does not always hold, and Mr. Hunter gives an instance of the contrary. The Romans, who called the bull *taurus*, spoke also of *tauræ*, in the feminine gender, different from *vaccæ* or cows. Stephens observes, that it was thought they meant by this word barren cows, who obtained this name because they did not conceive any more than bulls. He quotes a passage from Columella, lib. vi. cap. 22, "And, like the *tauræ*, which occupy the place of fertile cows, should be rejected or sent away." Among the reptile tribe, such as worms, snails, leeches, &c. hermaphrodites are very frequent. In the Memoirs of the French Academy, we have an account of this very extraordinary kind of hermaphrodites, which not only have both sexes, but do the office of both at the same time. Such are earth-worms, round-tailed worms found in the intestines of men and horses, land-snails, and those of fresh waters, and all the sorts of leeches. And, as all these are reptiles, and without bones, M. Poupert concludes it probable, that all other insects which have these two characters are also hermaphrodites. The method of coupling practised in this class of hermaphrodites, may be illustrated in the instance of earth-worms. These creep two by two, out of holes proper to receive them, where they dispose their bodies in such a manner as that the head of the one is turned to the tail of the other. Being thus stretched lengthwise, a little conical button or papilla is thrust forth by each, and received into an aperture of the other. Among the insects of the soft or boneless kind, there are great numbers, which are so far from being hermaphrodites, that they are of no sex at all. Of this kind are all the caterpillars, maggots, and worms, produced of the eggs of flies of all kinds: but the reason of this is plain; these are not animals in a perfect state, but disguises under which animals lurk. They have no business with the propagating of their species, but are to be transformed into winged animals, by putting off their coverings; and then only they are in their perfect state, and therefore then only shew the differences of sex, which are always in distinct animals, each being only male or female. These copulate, and their eggs produce these creatures, which shew no sex till they arrive at that perfect state again.

HERMAPHRODITE FLOWERS, in botany, are so called by the sexualists on account of their containing both the antheræ and stigma, the organs of generation, within the same calyx and petals. Of this kind are the flowers of all the classes in Linnaeus's sexual method, except the classes monœcia and diœcia; in the former of which, male and female flowers are produced on the same root; in the latter, on distinct plants from the same seed. In the class polygamia, they are always hermaphrodite flowers mixed with male or female, or both, either on the same or distinct roots.

In the plantain-tree the flowers are all hermaphrodite; in some, however, the anthera or male organ, in others the stigma or female organ, proves abortive. The flowers in the former class are styled female hermaphrodites; in the latter, male hermaphrodites. Hermaphrodites are thus as frequent in the vegetable kingdom as they are rare in the animal one. See BOTANY.

HERMAS, in botany, a genus of the monœcia order, and polygamia class of plants. Hermaphrodite; umbel terminating; involucre universal and partial; umbellets with truncate rays, the central one floriferous; petals five; stamina five, barren; seeds in pairs, suborbiculate; male, umbels lateral, with universal and partial involucre; umbellets many-flowered; petals five; stamina five, fertile. There are five species.

HERMATA, a kingdom and town in Borneo.

HERMES, [*Ἑρμης*, Gr. from *ἑρμηνεύς*, an interpreter,] the Greek name of the god Mercury. See MERCURY, and THOTH.

HERMES, surnamed **TRISMEGISTUS**, *i. e.* thrice greatest, an Egyptian or Phœnician priest or philosopher, and according to some a king; which triple office, they say, was the reason of this surname; though Suidas alleges, it was given him because he taught the doctrine of the Trinity. It is more probable, however, that he was so named on account of his great learning; for he is said to have wrote thirty-six books on divinity and philosophy, and six on physic. Clemens Alexandrinus has given a catalogue of his works; but none of them are extant, except a piece entitled *Poemander*, which is reckoned spurious. He taught the Egyptians chemistry, the art of land-measuring, the cultivation of the olive, the division of time into hours, and the use of hieroglyphics. He is supposed to have flourished under Ninus or Osiris, about A. M. 2076.

HERMES, or **HERMA**, among antiquaries, a sort of square or cubical figure of the god Mercury, usually made of marble, though sometimes of brass or other materials, without arms or legs, and planted by the Greeks and Romans in their cross-ways.

HERMETICAL ART, a name given to chemistry, on a supposition that Hermes Trismegistus was the inventor of the art, or that he excelled therein. See HERMES.

HERMETICAL PHILOSOPHY, is that which undertakes to solve and explain all the phenomena of nature, from the three chemical principles, salt, sulphur, and mercury.

HERMETICAL PHYSIC, or **MEDICINE**, is that system or hypothesis in the art of healing, which explains the causes of diseases, and the operations of medicine, on the principles of the hermetical philosophy, and particularly on the system of alkali and acid. It has been long exploded.

HERMETICAL SEAL, a manner of closing glass-vessels, for chemical operations, so very accurately, that nothing can exhale, not even the most subtle spirits. It is performed by heating the neck of the vessel in the flame of a lamp till it be ready to melt, and then with a pair of pincers twisting it close together. This chemists call putting on Hermes's seal. Vessels are also sealed hermetically; by stopping them with a stopple of glass, well luted, into the neck of the vessel; or, by turning another ovum philosophicum upon that wherein the matter is contained.

HERMHARPOCRATES, or **HERMARPOCRATES**, in antiquity, a deity, or figure of a deity, composed of Mercury and Harpocrates the god of Silence.

HERMIANI, or **HERMIATITÆ**, a sect of heretics in the second century, thus called from their leader Hermias, and also denominated Seleuciani. One of their distinguishing tenets was, that God is corporeal. Another, that Jesus Christ did not ascend into heaven with his body, but left it in the sun.

HERMIONE, in fabulous history, the daughter of Menelaus and Helen, who was betrothed to her cousin Orestes, but afterwards married to Pyrrhus, whom Orestes therefore killed in the temple of Apollo, and recovered Hermione.

HERMIONE, in ancient geography, a considerable city of Argolis. It was in ruins, except a few temples, in the time of Pausanias. It gave name to the

HERMIONICUS SINUS, a part of the Sinus Argolicus.

HERMIT, is derived from the Greek *ἡρετικός*, a desert, and, therefore should rather be written Eremit. Paul, surnamed the Hermit, is usually reckoned the first hermit; though St. Jerome at the beginning of the life of that saint, says, it is not known who was the first. Some think John the Baptist, others Elijah; others

make St. Anthony the founder of the eremitical life; but others say that he only re-kindled and heightened the fervour thereof, and that his disciples owned St. Paul of Thebes for the first that practised it. The persecutions of Decius and Valerian are supposed to have been the occasion. Several of the ancient hermits, though they lived in deserts, had numbers of religious accompanying them. There are also various orders and congregations of religious distinguished by the title of hermits; as, hermits of St. Augustine, of St. John Baptist, of St. Jerome, of St. Paul, &c.

HERMITAGE, the cell or habitation of a hermit; also any religious cell, built and endowed in a recluse place, and annexed to some large abbey, of which the superior was called a Hermit.

HERMOGENES, the first and most celebrated architect of antiquity, was, according to Vitruvius, born at Alanbada, a city in Caria. He built a temple of Diana at Magnesia; another of Bacchus at Tros; and was the inventor of several parts of architecture. He wrote a book on the subject, which is lost.

HERMOGENIANS, a sect of ancient heretics, so denominated from their leader Hermogenes, an African born in the second century. Their opinions were warmly opposed by Tertullian.

HERMON, or **AERMON**, in ancient geography, a mountain of the Amorites, called Sanior by the Phœnicians, and Sanir or Senir by the Amorites, on the E. of Jordan. It is also called Sion by Moses; but must not be confounded with the Sion of Jerusalem. It is comprised by profane writers under Libanus, or Antilibanus, with which it is joined on the E.

HERMUS, in ancient geography, a river of Ionia.

HERNANDRIA, **JACK-IN-A-BOX TREE**; a genus of the triandria order, and monœcia class of plants; natural order, Tricocœ. Male, calyx three-parted; corolla three-petaled; female, calyx truncate, quite entire; corolla six-petaled; drupe hollow, with an open mouth, and a moveable nucleus. There are two species, viz. *H. sonora*, whistling hernandria; and *H. ovigera*, egg-fruited hernandria. The first is an upright lofty tree; the flowers are of a pale yellow colour, in panicked racemes; the calyxes of the fruit are also yellow; the seeds are very oily. It is very common in the West Indies. Dr. Patrick Browne attributes the whistling noise to the cups that sustain, and partly envelope, the nuts; these, he adds, are very large, and as they move in the wind, produce sound enough to alarm unwary travellers.

HERNIA, a descent of a portion of the intestines or omentum out of their natural place; or rather, the tumour formed by that descent, popularly called a rupture. The word originally signifies the same with tumor scroti, called also ramex. Priscian says, that the ancient Marsi gave the appellation hernia to rocks; whence some think hernias thus called on account of their hardness. Scallinger derives it from the Greek *ἑρνος*, a branch. See SURGERY.

HERNIARIA, **RUPTURE-WORT**; a genus of the digynia order, and pentandria class of plants; natural order, Sarmientaceæ. Calyx five-parted; corolla none; stamina five, barren, besides the fertile ones; capsule one-seeded. There are four species. As none of these plants possess any beauty, they are rarely cultivated in gardens.

HERNOSAND, or **HERNOSUND**, a sea-port of Sweden on an island in the gulph of Bothnia. It has a great trade in linen. Lon. 17° 50½' E. Lat. 62. 38. N.

HERO, [*ἥρως*, Lat. *hæros*,] a man eminent for bravery; a man of the highest class in any respect, as "a hero in learning." A hero is thus distinguished, by F. Bouhours, from a great man, that the former is more daring, fierce, and enterprising, and the latter more prudent, thoughtful, and reserved. In this sense we say, Alexander was a hero, Julius Cæsar a great man.

HERO, in Pagan mythology, a great and illustrious person, of a mortal nature, but supposed to partake of immortality, and after his death to be placed among the number of the gods. The Greeks erected columns and other monuments over the tombs of their heroes, and established a kind of worship in honour of the manes both of their heroes and heroines. The Romans also raised statues in honour of their heroes; but there were six of a superior order, who were supposed to be admitted into the community of the twelve great gods; viz. Hercules, Bacchus, Æsculapius, Romulus, Castor, and Pollux. Authors distinguish between the worship which the ancients paid to their heroes, and that offered to their gods. The latter consisted of sacrifices and libations; the former

former was only a kind of funeral-honour, in which they celebrated their exploits, concluding the rehearsal with feasts.

HERO OF A POEM, or ROMANCE, is the principal personage, or he who acts the chief part in it. Thus the hero of the Iliad is Achilles; of the Odyssey, Ulysses; of the Æneid, Æneas; of Tasso's Jerusalem, Godfrey of Bulloign; of Milton's Paradise Lost, Adam; though Mr. Dryden will have the Devil to be Milton's hero, because he gets the better of Adam, and drives him out of Paradise.

HEROD, improperly styled the Great, the execrable tyrant of Judæa, was born at Ascalon, about B. C. 68. His father, Antipater the Idumean, (or Edomite,) appointed him governor of Galilee; Mark Antony made him tetrarch, or ethnarch; and he afterwards obtained the kingdom of Judæa, which was confirmed to him by Augustus, a short time before the birth of our Saviour; and thus the prophecy was fulfilled, of "the sceptre departing from Judah," he being an alien by birth. At the birth of our Lord, in the vain hope of cutting off the Messiah, he caused all the infants of Bethlehem under two years of age to be massacred. His barbarity was as fatal to his own family as to his subjects; for he murdered his beautiful wife Mariamne, her mother Alexandra, her brother Aristobulus, her grandfather Hyrcanus II. and his own sons Alexander and Aristobulus; which led the emperor Augustus to say, that it was better to be Herod's swine than his sons. He died miserably within three years after the birth of Christ, aged 70.

HEROD ANTIPAS, the son of Herod the Great, by his wife Cleopatra, a native of Jerusalem. Herod, in his will, named his son Archelaus his successor, giving Antipas the title of Tetrarch of Galilee and Peræa. Antipas adorned and fortified the principal places of his dominions. He married the daughter of Aretas, King of Arabia; whom he divorced about A. D. 33, to marry his sister-in-law Herodias, wife to his brother Philip, who was still living. St. John the Baptist, exclaiming against this incest and adultery, was imprisoned in the castle of Machærus; and afterwards beheaded by Herod's order, as recorded in Mat. xiv. Mark vi. and Luke iii. Aretas to revenge the affront which Herod had offered to his daughter, declared war against him, and overcame him in a very obstinate engagement. Herod being afterwards detected as a party in Sejanus's conspiracy, was banished by the emperor Caligula into Lyons in Gaul; whither Herodias accompanied him. This Antipas is the Herod who, being at Jerusalem at the time of our Saviour's passion, (Luke xxiii. 11,) ridiculed him, by dressing him in a white robe, and sending him back to Pilate, as a mock king; whose ambition gave him no umbrage. The time when he died is not known, but it is certain he died in exile, as well as Herodias. Josephus says he died in Spain.

HERODIAN, an eminent Greek historian, who flourished at Rome in the third century, in the reigns of Severus, Caracalla, Heliogabalus, Alexander, and Maximin. His history begins from the death of Marcus Aurelius the philosopher; and ends with those of Balbinus and Maximin, and the beginning of the reign of Gordian. It is written in very elegant Greek; and there is an excellent translation of it into Latin, by Angelus Politianus. It was published by Henry Stephens in 4to, in 1581; by Boeder, at Strasburg, in 1662, in 8vo.; and by Hudson, at Oxford, in 1699, 8vo.

HERODIANS, a sect among the Jews, mentioned in Matth. xxii. 16, and Mark iii. 6. Commentators are much divided with regard to them. St. Jerome, in his dialogue against the Luciferians, takes the name to have been given to such as owned Herod for the Messiah; and Tertullian and Epiphanius are of the same opinion. But the same Jerome, in his Comment on St. Matthew, treats this opinion as ridiculous; and maintains, that the Pharisees gave this appellation by way of ridicule to Herod's soldiers, who paid tribute to the Romans; agreeable to this the Syrian interpreters render the word by the domestics of Herod, i. e. Herod's courtiers. M. Simon, in his notes on the twenty-second chapter of Matthew, advances a more probable opinion. The name he supposes to have been given to such as adhered to Herod's party and interest; and were for preserving the government in his family, about which there were great divisions among the Jews. F. Hardouin will have the Herodians and Sadducees to have been the same. Dr. Prideaux is of opinion, that they were distinguished from the other Jews by their concurrence with Herod's scheme,

of subjecting himself and his dominions to the Romans; and by complying with many of their heathen usages and customs. This symbolizing with idolatry upon views of interest and worldly policy, was probably that leaven of Herod, against which our Saviour cautioned his disciples. It is farther probable, that they were chiefly of the sect of the Sadducees; because the leaven of Herod is also called the leaven of the Sadducees.

HERODOTUS, an ancient Greek historian, the son of Lyxus and Dryo, born at Halicarnassus in Caria, in the first year of the seventy-fourth Olympiad, about B. C. 484. Halicarnassus being at that time under the tyranny of Lygdamis, grandson of Artemisia, Queen of Caria, Herodotus retired to Samos; from whence he travelled over Egypt, Greece, Italy, &c. and acquired the knowledge of the history and origin of many nations. He then began to digest the materials he had collected, and composed that history which has preserved his name ever since. He wrote it in the isle of Samos. Lucian informs us, that when Herodotus left Caria to go into Greece, he began to consider with himself,

What he should do to be for ever known,

And make the ages all to come his own.

His history, he presumed, would easily procure him fame, and raise his name among the Grecians, in whose favour it was written; but then he saw that it would be tedious to go through all the cities of Greece, and recite it to the inhabitants of each city. He thought it best therefore to take the opportunity of their assembling all together; and accordingly recited his work at the Olympic games, which rendered him more famous than even those who had obtained the prizes. None were ignorant of his name, nor was there a single person in Greece who had not either seen him at the Olympic games, or heard those speak of him who had seen him there. His work is divided into nine books; which, according to the computation of Dionysius Halicarnassensis, contain the most remarkable occurrences within a period of 240 years; from the reign of Cyrus to that of Xerxes, when the historian was living. These nine books are named after the nine Muses, each book being distinguished by the name of a Muse; and this has given birth to two disquisitions; viz. 1. Whether they were so called by Herodotus himself; and, 2. For what reason they were so called. As to the first, it is generally agreed that Herodotus did not impose these names himself; but it is not agreed why they were imposed by others. Lucian tells us, that these names were given them by the Grecians at the Olympic games, when they were first recited, as the best compliment that could be paid the man who had taken pains to do them so much honour. Others have thought, that the names of the Muses have been fixed upon them by way of reproach, to intimate, that Herodotus, instead of true history, had written a great deal of fable. Aldus Manutius, Joachim Camerarius, and Henry Stephens, have written apologies for him; and have very justly observed, that he seldom relates any thing of doubtful credit without producing the authority on which his narration is founded; and, if he has no certain authority to fix it upon, uses always the terms, *ut ferunt*, *ut ego audivi*, &c. There is ascribed also to Herodotus, but falsely, a Life of Homer, which is usually printed at the end of his work. He wrote in the Ionic dialect, and his style and manner have been admired by all people of taste. There have been several editions of his works; two by Henry Stephens, in 1570, and 1592; one by Gale at London in 1679; and one by Gronovius at Leyden in 1715, which is the best, though not the best printed.

HEROIC AGE, is that age or period of the world, wherein the heroes, or those called by the poets the children of the gods, are supposed to have lived. It coincides with the fabulous age.

HEROIC POEM is that which undertakes to describe some extraordinary action, or enterprise. Homer, Virgil, Statius, Lucan, Tasso, Camoens, Milton, and Voltaire, have composed heroic poems. In this sense, heroic poem coincides with epic poem.

HEROIC VERSE, is that wherein heroic poems are usually composed; or, it is that proper for such poems. In the Greek and Latin, hexameter verses are peculiarly denominated heroic verses, as being alone used by Homer, Virgil, &c. Alexandrine verses, of twelve syllables, were formerly called heroic verses, as being supposed the only verse proper for heroic poetry; but later writers use verses of ten syllables.

HERON, in ornithology. See ARDEA. This bird is a very great devourer of fish, and will do more mischief to a pond than even

even an otter. The readiest method of destroying this mischievous bird is by fishing for him in the manner of pike, with a baited hook; the bait consisting of small roach or dace, and the hook fastened to one end of a strong line, made of silk and wire twisted together. The wire should be entered under the gills of the roach, and run just under the skin to the tail; in which condition the fish will live several days: for if it be dead, the heron will not touch it. To the other end of the line is fastened a stone of a pound weight; and several of these baited lines being sunk by means of the stone in different parts of the pond, in a night or two the heron will certainly be taken.

HERPES, [*hɛrɪs*,] a cutaneous inflammation of two kinds: miliaris, or pustularis, which is like millet-seed upon the skin; and excedens, which is more corrosive and penetrating, so as to form little ulcers.

HERRING. See **CLUPEA**.

HERRING-FISHERY. Our great stations for this fishery are off the Shetland and Western Isles. There are two seasons for it; the first from June to the end of August; and the second in Autumn, when the fogs become very favourable for this kind of fishing. The Dutch begin their herring-fishing on the twenty-fourth of June, and employ a vast number of vessels therein; called busses, being between forty-five and sixty tons burden each, and carrying three or four small cannon. They never stir out of port without a convoy, unless there be enough together to make about eighteen or twenty cannon among them, in which case they are allowed to go in company. Before they go out, they make a verbal agreement, which has the same force as if it were in writing. The regulations of the admiralty of Holland are partly followed by other nations, and partly improved and augmented with new ones; as, that no fisher shall cast his net within 100 fathoms of another boat: that while the nets are cast, a light shall be kept on the hind part of the vessel: that when a boat is by any accident obliged to leave off fishing, the light shall be cast into the sea; that when the greater part of a fleet leaves off fishing, and casts anchor, the rest shall do the same, &c. The vast advantage of this fishery to our nation is very obvious, when we consider that though herrings are found upon the shores of North America, they are never seen there in such quantities as with us, and that they are not to be met with in considerable numbers in any of the southern kingdoms of Europe as Spain, Portugal, or the south parts of France on the side of the ocean, or in the Mediterranean, or on the coast of Africa. Numerous attempts have been made at different periods to secure this treasure to ourselves, but with little success. In the late reign, a very strong effort was made, and bounties allowed for the encouragement of British adventurers: the first was of 30s. per ton to every buss of seventy tons and upwards. This bounty was afterwards raised to 50s. per ton, to be paid to such adventurers as were entitled to it by claiming it at the places of rendezvous. The busses are from twenty to ninety tons burden, but the best size is eighty. A vessel of eighty tons ought to take ten lasts, or 120 barrels of herrings, to clear expences, the price of the fish to be admitted to be a guinea a barrel. A ship of this size ought to have eighteen men, and three boats: one of twenty tons should have six men; and every five tons above require an additional hand. To every ton are 280 yards of nets; so a vessel of eighty tons carries 20,000 square yards: each net is twelve yards long, and ten deep; and every boat takes out from twenty to thirty nets, and puts them together, so as to form a long train; they are sunk at each end of the train by a stone, which weighs it down to the full extent: the top is supported by buoys, made of sheep's skin, with a hollow stick at the mouth, fastened tight; through this the skin is blown up, and then stopped with a peg, to prevent the escape of the air. Sometimes these buoys are placed at the top of the nets; at other times the nets are suffered to sink deeper, by lengthening the cords fastened to them, every cord being for that purpose ten or twelve fathoms long. But the best fisheries are generally in more shallow water. Loch-broom has been celebrated for three or four centuries as the resort of herrings. They generally appear there in July: those that turn into this bay are part of the brigade that detaches itself from the western column of that great army which annually deserts the vast depths of the arctic circle, and come, heaven-directed, to the seats of population, offered as a cheap food to millions, whom wasteful luxury or iron-hearted avarice hath deprived, by enhancing the price of the wonted supports of the poor. The migration of these fish from

their northern retreat is regular; their visits to the western isles and coasts, certain; but their attachment to one particular loch, extremely precarious. All have their turns: that which swarmed with fish one year is totally deserted the following; yet the next loch to it may be crowded with the shoals. These changes of place give often full employ to the busses, who are continually shifting their harbour in quest of news respecting these important wanderers. They commonly appear here in July; the latter end of August they go into deep water, and continue there for some time, without any apparent cause: in November, they return to the shallows, when a new fishery commences, which continues till January; at that time the herrings become full of roe, and are useless as articles of commerce. Some doubt whether those herrings that appear in November are not part of a new migration; for they are as fat, and make the same appearance, as those that composed the first. The signs of the arrival of the herrings are flocks of gulls, who catch up the fish while they skim on the surface; and of gannets, who plunge and bring them up from considerable depths. Both these birds are closely attended to by the fishers. Cod-fish, haddocks, and dog-fish, follow the herrings in vast multitudes; these voracious fish keep on the outsides of the columns, and may concur in driving the shoals into bays and creeks. In summer, they come into the bays generally with the warmest weather, and with easy gales. During winter, the hard gales from N. W. are supposed to assist in forcing them into shelter. East winds are very unfavourable to the fishery.

HERRINGS, METHOD OF SALTING. The nets being hauled on board, the fishes are taken out, and put into the warbacks, which stand on one side of the vessels. When all the nets are thus unloaded, one fills the gippers' baskets. The gippers cut their throats, take out their guts, and fling out the full herrings into one basket, and the shotten into another. One man takes the full basket when they are gipped, and carries them to the rower back, wherein there is salt. One boy rows and stirs them about in the salt, and another takes them, thus rowed, and carries them in baskets to the packers. Four men pack the herrings into one barrel, and lay them, one by one, straight and even; and another man, when the barrel is full, takes it from the packers. It is left to stand a day or more open to settle, that the salt may melt and dissolve to pickle; after which it is filled up, and the cooper completes the work, by heading the casks very tight, and stowing them in the hold. The pickle is to be strong enough to sustain a herring; otherwise the fish decay in it.

HERRINGS, RED, must lie twenty-four hours in the brine, as they are to take all their salt there. When taken out, they are spitted, that is, strung by the head on little wooden spits, and then hung in a chimney made for that purpose. After which, a fire of brush-wood, which yields a great deal of smoke, but no flame, being made under them, they remain there till sufficiently smoked and dried, and are then barrelled up for keeping.

HERRNHUTTERS, a sect of Christians, named also Moravians and United Brethren. See **UNITED BRETHREN**.

HERSCHEL, the name given by most foreigners to the new planet, called Georgium Sidus by Mr. Herschel, who discovered it. See **ASTRONOMY**. This planet is also called Uranus.

HERSE, [*herce*, Fr. *h. c.* a harrow,] in fortification, a lattice, or portcullis, in form of a harrow, beset with iron-spikes. It is usually hung by a rope fastened to a maulinet; to be cut, in case of surprise, or when the first gate is broken with a petard, that the herse may fall, and stop up the passage of the gate or other entrance of a fortress. It is otherwise called a sarrasin, or cataract; and when it consists of straight stakes, without any cross pieces, it is called orgues.

HERSE is also a harrow, which the besieged, for want of chevaux de frise, lay in the way, or in breaches, with the points up, to incommode the march of the enemy's horse or infantry.

HERSFELD, a late territory of Germany, in the circle of the Upper Rhine, which belonged to the Prince of Hesse Cassel. It now forms a part of the kingdom of Westphalia, under the government of Jerome Napoleon.

HERSFELD, or **HIRSCHFELD**, the capital of the above territory, 32 miles S. S. E. of Cassel, and 50 W. of Erfurt.

HERSILLON, in the military art, a sort of plank or beam, ten or twelve feet long, whose two sides are driven full of spikes or nails, to incommode the march of the infantry or cavalry. The word is a diminutive of herse. See **HERSE**.

HERTFORD, the county of Hertfordshire. In the beginning of the heptarchy it was considered as one of the principal cities of the East Saxons. It is 21 miles N. of London.

HERTFORD, a county and town of North Carolina, in Edenton district.

HEREFORDSHIRE, or **HERTS**, a county of England, bounded on the north by Cambridgeshire, on the east by Essex, on the north west by Bedfordshire, on the west by Bucks, and on the south by Middlesex. It is 36 miles long from north to south, and 28 broad from east to west. It is divided into eight hundreds, which contain nineteen market-towns, and a hundred and seventy-four parishes. Flint-stones are scattered in great profusion over it, and beds of chalk are frequently met with. It is, however, with proper culture, extremely favourable to wheat and barley, which come to as great perfection here as in any part of the kingdom.

HERTHA, or **HERTHUS**, in mythology, a goddess worshipped by the ancient Germans. She is mentioned by Tacitus, in his book *De Moribus Germanorum*, cap. 40. Vossius supposes that this goddess was Cybele: but she was more properly Terra, or the Earth; for the Germans still use her for the earth, whence also the English word earth.

HERTZBERG, a considerable town of Saxony, 24 miles S.E. of Wittenberg, and 35 N.W. of Dresden.

HERVORDEN, or **HERWARDEN**, a town in Westphalia, 17 miles S.W. of Minden.

HESDIN, a strong town of France, in the department of the Straights of Calais, and late county of Aortis, 25 miles S.S.W. of St. Omer, and 165 N. of Paris.

HESIOD, a very ancient Greek poet; but whether contemporary with Homer, or a little older or younger, is not agreed among the learned. His father, as he tells us in his *Opera et Dies*, was an inhabitant of Cumæ, one of the Eolian isles, now called *Taio Nova*; and removed from thence to Ascra, a little village of Boeotia, at the foot of mount Helicon, where Hesiod was probably born, and called, as he often is, *Ascreus*, from it. Of what quality his father was it is no where said; but that he was driven by misfortunes from Cumæ to Ascra Hesiod himself informs us. His father seems to have prospered better at Ascra, than he did in his own country; yet Hesiod could arrive at no higher fortune than keeping sheep on the top of mount Helicon. Here the Muses met with him, and entered him into their service, as he boasts in his *Generatio Deorum*:

Erewhile as they the shepherd swain behold,
Feeding beneath the sacred mount his fold,
With love of charming song, his breast they fir'd:
There me the heav'nly muses first inspir'd;
There, when the maids of Jove the silence broke,
To Hesiod thus the shepherd swain they spoke, &c.

On the death of the father, an estate was left which ought to have been equally divided between Hesiod and his brother Perses; but Perses defrauded him in the division, by corrupting the judges. Hesiod was so far from resenting this injustice, that he expresses a concern for those mistaken mortals who place their happiness in riches only, even at the expence of their virtue. He let us know, that he was not only above want, but capable of assisting his brother in time of need, which he often did, though he had been so ill used by him. The last circumstance he mentions relating to himself is his conquest in a poetical contention. Archidamus, king of Eubœa, had instituted funeral-games in honour of his own memory, which his sons afterwards took care to have performed. Here Hesiod was a competitor for the prize in poetry; and won a tripod, which he consecrated to the muses. When he was grown old (for it is agreed by all that he lived to a very great age), he removed to Locris, a town about the same distance from mount Parnassus as Ascra was from Helicon. His death was tragical. The man with whom he lived at Locris, a Milesian born, ravished a maid in the same house; and though Hesiod was entirely ignorant of the fact, yet being maliciously accused to her brothers as an accomplice, he was unjustly slain with the ravisher, and thrown into the sea. The *Theogony*, and his *Works and Days*, are the only undoubted pieces of this poet now extant; but it is supposed that even these have not come to us complete. A good edition of Hesiod's works was published by Mr. Le Clerc, at Amsterdam in 1701.

HESIONE, in fabulous history, the daughter of Laomedon, king of Troy, and sister of king Priam.

HESPER, or **HESPERUS**, [*Ἑσπερος*,] in astronomy, the evening-star; an appellation given to Venus when she follows or sets after the sun. See **HESPERUS**.

HESPERIA, or **HESPERIA MAGNA**, an ancient name of Italy; so called by the Greeks from its western situation.

HESPERIDEÆ, in botany, from the *Hesperides*; golden, or precious fruit: the nineteenth order in Linnæus's *Natural Method*. See **BOTANY**.

HESPERIDES, in ancient mythology, the grand-daughters of Hesperus, the brother of Atlas. According to Diodorus, these brothers possessed great riches in the western parts of Africa. Hesperus had a daughter called Hesperia, who married her uncle Atlas, and from this marriage proceeded seven daughters, called *Hesperides* from the name of their mother, and *Atlantides* from that of their father. According to the poets, the *Hesperides* were three in number, *Ægle*, *Arethusa*, and *Hesperethusa*. Hesiod, in his *Theogony*, makes them the daughters of Nox, Night, and seats them in the same place with the Gorgons, viz. at the extremities of the west near mount Atlas; because the sun sets there.

HESPERIDES, **GARDENS OF THE**, in ancient geography, are placed by some authors at Larach, a city of Fez; by others, at Bernich, a city of Barca, which accords better with the fable. Others take the province of Susa in Morocco for the island where in the garden was seated.

HESPERIS, **ROCKET**, **DAME'S VIOLET**, or **QUEEN'S GIL-LIFLOWER**; a genus of the siliquosa order, and tetradynamia class of plants; natural order, *Siliquosæ*. Petals turned obliquely; glandule within the shorter stamina; siliqua almost upright; stigma forked at the base, connivent, or closing at the top; calyx close. There are seven species cultivated, on account of the great fragrancy of the flowers.

HESPERUS, in the mythology, the brother of Atlas, and grandfather of the *Hesperides*. Diodorus, lib. iii. relates that Hesperus, having ascended to the top of mount Atlas, the better to observe the stars, never returned; and hence he was fabled to have been changed into the evening-star.

HESSE, a country in the late circle of the Upper Rhine, in Germany, bounded on the north by the bishopric of Paderborn and duchy of Brunswick; on the east by Thuringia; on the south by the territory of Fulde and Weteravia; and on the west by the counties of Nassau, Witgenstein, Harzfeldt, and Waldeck. The house of Hesse is divided into four branches, namely, Hesse-Cassel, Homburg, Darmstadt, and Rhinefeldt, each of which has the title of landgrave, and takes its name from one of the four principal towns.

HESSIAN FLY, a very mischievous insect, native of the Land-gravate Hesse, whence it has received its name. This insect is particularly destructive to wheat-corn, in which it deposits its eggs close to the ground, while growing. When the young vermin are hatched, they continue for some time in a worm-state, feeding on the tender part of the stalk, the growth of which is thus effectually checked. The Hessian fly committed great depredations in the eastern counties of England, several years since; and in the year 1787, did incalculable damage in the provinces of Pennsylvania and Maryland, in America. Several remedies against this destructive insect have been proposed; the only efficacious one hitherto discovered, consists in facilitating the vigorous growth of the plants, by properly manuring and cultivating the soil. In order to prevent the depredations of this insect, it has been recommended to mix three pounds of turnip-seed with one ounce of flour of sulphur in a glazed earthen-pot, which should be closely covered. After standing twenty-four hours, another ounce of sulphur should be added, and the same quantity after forty-eight hours, so as to employ three ounces of this powder to three pounds of seed, carefully stirring the whole every time the vessel is opened, with a smooth piece of wood or ladle, that the seed may be thoroughly impregnated with the sulphur. It is then to be sown on an acre of ground, in the usual manner, where it will effectually keep off the insect till the third or fourth seeding-leaf is formed, which will acquire a bitterish taste, and thus be secured from the depredations of the fly. Another remedy is, to strew tobacco-dust over the land; and in some counties the seeds are steeped in soot and water for several hours previously to being sown, by which they acquire such a degree of bitterness, as to screen them completely against the ravages of this noxious insect.

HESYCHIUS, the most celebrated of all the ancient Greek grammarians,

lib. vi. cap. 16,) relates that Origen, after his return from Rome under Caracalla, learned Hebrew, and began to collect the several versions that had been made of the sacred writings, and of these to compose his Tetrapla and Hexapla. But others say that he did not begin till the time of Alexander, after he had retired into Palestine, about A. D. 231. Besides the translation of the sacred writings, called the Septuagint, made under Ptolemy Philadelphus, about B. C. 280, the Scriptures had been since translated into Greek by other interpreters. The first of those versions, or (reckoning the Septuagint) the second, was that of Aquila, a proselyte Jew, the first edition of which he published in the twelfth year of Adrian, or about A. D. 128; the third was that Symmachus, published, as is supposed, under Marcus Aurelius, but, as some say, under Septimius Severus, about A. D. 200; the fourth was that of Theodotion, prior to Symmachus's, under Commodus, or about A. D. 175. These Greek versions, says Dr. Kennicott, were made by the Jews from their corrupted copies of the Hebrew, and were designed to stand in the place of the Seventy, against which they were prejudiced, because it seemed to favour the Christians. The fifth was found at Jericho, in the reign of Caracalla, about A. D. 217; and the sixth was discovered at Nicopolis, in the reign of Alexander Severus, about A. D. 228; lastly, Origen himself recovered part of a seventh, containing only the Psalms. Origen, who had held frequent disputations with the Jews in Egypt and Palestine, observing that they always objected to those passages of Scripture quoted against themselves, and appealed to the Hebrew text; the better to vindicate those passages, and confound the Jews by shewing that the Seventy had given the sense of the Hebrew, or rather to shew, by a number of different versions, what the real sense of the Hebrew was, undertook to reduce all the several versions into a body along with the Hebrew text, so as they might be easily confronted, and afford a mutual light to each other. He made the Hebrew text his standard; and, allowing that corruptions might have happened, and the old Hebrew copies might and did read differently, he marked such words or sentences as were not in his Hebrew text, nor the latter Greek versions, and added such words or sentences as were omitted in the LXX, prefixing an asterisk to the additions, and an obelisk to the others. For this purpose, he made eight columns; in the first he gave the Hebrew text in Hebrew characters; in the second the same text in Greek characters; the rest were filled with the several versions above-mentioned; all the columns answering verse for verse, and phrase for phrase; and in the Psalms there was a ninth column for the seventh version. This work Origen called *Ἑξάπλη*, Hexapla, *q. d.* sextuple, or a work of six columns, as only regarding the first six Greek versions. St. Epiphanius, taking in likewise the two columns of the text, calls the work Octapla, as consisting of eight columns. This celebrated work, which Montfaucon imagines consisted of fifty large volumes, perished long ago, probably with the library at Casarea, where it was preserved in 653; though several ancient writers have preserved pieces of it, particularly St. Chrysostom on the Psalms, Philoponus in his Hexameron, &c. Some modern writers have earnestly endeavoured to collect fragments of the Hexapla, particularly Flaminii Nobilius, Drusius, and F. Montfaucon, in two folio volumes, printed at Paris in 1713.

HEXASTIC, [*ἑξάστις* and *ἑξάστις*] a poem of six lines.

HEXASTYLE, in architecture, a building with six columns in front.

HEXHAM, a town of Northumberland, on the Tyne, noted for its manufactory of tanned leather, shoes, and gloves; and is twenty-two miles W. of Newcastle.

HEYDON, a borough in the E. Riding of Yorkshire, six miles W. of Hull.

HELYSHEM, a town of France in the department of the Dyle, and late province of Austrian Brabant: 14 miles S. E. of Louvain.

HEYMERISEN, a town of Germany, in the late electorate of Cologne, 5 miles W. of Bonne.

HEZEKIAH, or **EZEKIAS**, [הזקיה, Heb. *i. e.* The strength of Jah, or Jehovah,] one of the best kings of Judea, succeeded his father Abaz, A. M. 3278. His reformation of his subjects from idolatry; his grand and solemn celebration of the passover; his invitation to the Israelites to assist at it; his throwing off the Assyrian yoke; his miraculous deliverance from the invasion by Sennacherib, after the blasphemous defiance of Rabshakeh; his mor-

tal disease, prophetic prayer, and miraculous recovery, with the fatal consequences of his vanity after it, are recorded in 2 Kings xviii.—xx. 2 Chron. xxix.—xxxii. and Isaiah xxxvi.—xxxix. The hymn he composed upon his recovery, (Isa. xxxviii.) entitles him to be ranked among the Types of Christ. He collected a part of Solomon's Proverbs. (See Prov. xxvi.) Upon the miraculous retrogression of the shadow on Abaz's dial, we need say little. Those who doubt the existence of a Deity, or deny his power over the material world, will not be convinced by any arguments. But those who believe that the Almighty, when he gave existence to matter, and subjected it to certain laws, did not thereby limit his own infinite power, will not think it more incredible, that he who created light by his word should invert the shadow of the gnomon, so as to make it appear to have gone 10 degrees backward, than that a watchmaker should turn back the hour or minute hand of a clock, in a direction contrary to the natural motion which he himself has given it. How this was done, whether by a momentary retrograde motion given to the terrestrial globe, or only by an inversion of the usual motion of the solar rays upon the gnomon, it is neither necessary nor possible to determine. The former supposition seems most probable. Upon this supposition it must have been observed over one half of the globe; and that it was observed by the Chaldean astronomers who resided at Babylon, seems evident from Merodach-Baladan's congratulatory embassy on Hezekiah's recovery. Hezekiah died in the 54th year of his age, and 29th of his reign; A. M. 3307.

HIAMEN, or **EMOUY**, an island near the S. E. coast of China, in the province of Fokien, about 15 miles in circumference; with an extensive port capable of containing several thousands of vessels, protected on one side by the island, and on the other by the main-land. The water is so deep that the largest ships may lie close to the shore without danger. Lon. 1. 52. E. of Pekin. Lat. 24. 30. N.

HIARBAS, in fabulous history, a king of the Getulians, who made war against Queen Dido.

HIATUS, [*hiatus*, Lat.] an aperture; a gaping breach; the opening of the mouth by the succession of an initial to a final vowel. It is particularly applied to those verses where one word ends with a vowel, and the following word begins with one, and thereby occasions the mouth to be more open, and the sound to be very harsh. It is also used in speaking of manuscripts, to denote their defects, or the parts that have been lost or effaced.

HIBERNIA, one of the ancient names of Ireland, is derived by some from *hibernum tempus*, winter-time, because in that season the nights are long there. But it appears more probable that it has been derived from *Erin*, the name given to the island by the original inhabitants: whence *Jerna*, the name given it by Claudian, *Iverna*, by Ptolemy, and *Juvena*, by Juvenal, are evidently derived.

HIBISCUS, **SYRIAN MALLOW**; a genus of the polyandria order, and monadelphia class of plants: natural order, Columnifera. Calyx double; outer many-leaved; capsule five-celled, with many seeds. There are forty-five species; most of these are perennials; several of them have shrubby stalks; and some are herbaceous; the leaves are alternate and commonly of a soft texture. The flowers are of the mallow-kind, axillary, and terminating; the bark in several is capable of being drawn into threads, and manufactured for packthread and ropes; the capsule in some is eatable; others are much esteemed for their ornamental flowers.

HICCUGH, or **HICKUP**, is a spasmodic affection of the stomach, œsophagus, and muscles, subservient to deglutition, arising from various causes, such as a fit of laughing, thirst, cold drinks, suppression of diarrhoea, antipathy, &c. It can by no means be considered as a disease, though a few instances have occurred, in which it has continued for three or four years; and one in which it became habitual, and could not be removed. Persons who eat large meals, and load the stomach by drinking profusely after them, or those liable to flatulency, are chiefly subject to this affection. The common hiccough seldom requires any medicine to remove it, as it generally disappears after drinking a few small draughts of water in quick succession.

HIDAGE, or **HIDAGIUM**, was an extraordinary tax payable to the kings of England for every hide of land. This taxation was levied not only in money, but in provision, armour, &c.; and when

when the Danes landed in Sandwich in 994, king Ethelred taxed all his lands by hides; so that every 310 hides found one ship furnished, and every 8 hides furnished one jack and one saddle, to arm for the defence of the kingdom, &c.

HIDALGO, in modern history, a title given in Spain to all who are of noble family. The Hidalgos claim a descent from those valiant soldiers who retired into Castile, and the mountains of Asturias, and other remote parts of Spain, on the invasion of the Moors, where having fortified themselves, they successively descended into the plains, in proportion to the success of their arms: from the notoriety of their persons, or the lands they became possessed of, they acquired the appellation of Hidalgos notorios, Hidalgos de dolor conocido, or de casa solariega.

HIDDEKEL, the third river in Paradise. (Gen. ii. 14.) It is supposed to be the same with the Tigris, called Diglat by the Arabs. It runs S. between Assyria on the E. and Mesopotamia on the W. and falls into the Euphrates. It is said by Moses to run toward the E. of Assyria, which it does in respect of his situation.

HIDE, [*hyde*, Sax.] generally speaking, signifies the skin of beasts, but is particularly applied to those of large cattle, such as bullocks, cows, horses, &c. Hides are either raw or green, that is, in the same state as when they were taken off the carcass; salted or seasoned, in which case they are dressed with salt, alum, and salt-petre, to prevent them from putrefying; or they are curried or tanned; for an account of which processes, See **TANNING**.

HIDE OF LAND, was as much as would maintain a family; some call it 60, some 80, and others 100 acres.

HIDBOUNDNESS. See **FARRIERY**.

HIERACUM, **HAWKWEED**; a genus of the polygamia æqualis order, and syngenesia class of plants; natural order, Compositæ. Receptacle naked; calyx imbricate, ovate; down simple, sessile. The species are fifty-five, most of them weeds.

HIERAPOLIS, in ancient geography, a town of Phrygia, abounding in hot springs, and having its name from the number of its temples. It is now called Pambouk; and is situated near the Scamander, on a portion of Mount Mesogis, 6 miles from Laodicea.

HIERARCH, [*ἱεραρχ*, and *αρχων*, Gr.] the chief of a sacred order.

HIERARCHY, a sacred government; rank or subordination of holy beings. Some of the rabbins reckon four, others ten, orders or ranks of angels; and give them different names according to their supposed degrees of power and knowledge.

HIERARCHY, also denotes the subordination of the clergy, ecclesiastical polity, or the constitution and government of the Christian church considered as a society.

HIERES, a town of France, in the department of Var and late province of Provence, 12 miles E. of Toulon.

HIERES, four islands of France, on the coast of Provence; called Porquerollos, Porteros, and Bagueau, which are inhabited, and Titan; which last is the largest and is capable of cultivation.

HIERO II, K. of Syracuse was a descendant of Gelon, and was elected king B. C. 268. He carried on war against the Romans for some time along with the Carthaginians; but made peace, and continued ever after their firm ally. He was a relation of Archimedes: and was a prince of great learning and virtue, and encouraged arts and commerce. He died B. C. 225.

HIERO'S CROWN, in hydrostatics. Hiero II. having furnished a goldsmith with a quantity of fine gold to make a crown, suspected, upon receiving it, that he had been cheated, by his using a greater quantity of silver-alloy than was necessary. He applied to Archimedes to discover the fraud without defacing the crown; which he did by this experiment: He procured a ball of pure gold, and another of silver, each exactly of the same weight with the crown: and judging that if the crown were of pure gold it would be of equal bulk, and upon putting it in water, expel an equal quantity of the water with the golden ball; if of silver, it would expel an equal quantity with the silver one; but, if of an intermediate quality, the quantity of water expelled would be in exact proportion. This upon trial he found to be the case; and by comparing the quantities of water displaced, discovered the exact proportions of gold and silver in the crown. The following example will shew the process: suppose each of the three masses

above referred to weigh 64 ounces, and that immersing them separately in the same vessel of water, there were displaced 5oz. of water by the golden ball, 9oz. by the silver, and 6oz. by the compound, or the crown itself, then the respective bulks being as the quantities of water displaced, will be as 5, 9, and 6; and we say,

$$9 - 6 = 3$$

$$6 - 5 = 1$$

$$\frac{4}{-}$$

$$4 : 64 :: 3 : 48$$

$$4 : 64 :: 1 : 16$$

And under such circumstances the crown consisted of 48oz. of gold and 16 of silver.

HIEROGLYPHS, or, **HIEROGLYPHICS**, [*ἱερος*, sacred, and *γλυφω*, to carve,] in antiquity, mystical characters or symbols, in use among the Egyptians, and that, as well in their writings as inscriptions; being the figures of various animals, the parts of human bodies, and mechanical instruments. It was the custom to have the walls, doors, &c. of their temples, obelisks, &c. engraven with such figures. Hieroglyphics are properly emblems or signs of divine, sacred, or supernatural things; by which they are distinguished from common symbols, which are signs of sensible and natural things. Hermes Trismegistus is commonly esteemed the inventor of hieroglyphics: he first introduced them into the heathen theology, from whence they have been transplanted into the Jewish and Christian. Sacred things, says Hippocrates, should only be communicated to sacred persons. Hence the ancient Egyptians communicated to none but their kings and priests, and those who were to succeed to the priesthood and the crown, the secrets of nature, of their morality and history; and this they did by a kind of cabbala, which, at the same time that it instructed them, only amused the rest of the people. Hence the use of hieroglyphics, or mystic figures, to veil their morality, politics, &c. from profane eyes. This author and many others do not keep to the precise character of a hieroglyphic, but apply it to profane as well as divine things. Hieroglyphics are a kind of real characters, which do not only denote, but in some measure express, the things. Thus, according to Clemens Alexandrianus, (Strom. v.) a lion is the hieroglyphic of strength and fortitude; a bullock, of agriculture; a horse, of liberty; a sphinx, of subtilty, &c. Such is the opinion that has generally been embraced, both by ancient and modern writers, of the origin and use of hieroglyphics. It has been almost uniformly maintained, that they were invented by the Egyptian priests to conceal their wisdom from the knowledge of the vulgar; but the late bishop Warburton has with much ingenuity and learning, endeavoured to shew that this account is erroneous. He thinks, the first kind of hieroglyphics were mere pictures, because the most natural way of communicating our conceptions, by marks or figures, was by tracing out the images of things; and this is verified in the case of the Mexicans, whose only method of writing their laws and history was by this picture-writing. But the hieroglyphics invented by the Egyptians were an improvement on this rude and inconvenient essay towards writing, for they contrived to make them both pictures and characters. In order to effect this improvement, they were obliged to proceed gradually, by first making the principal circumstance of the subject stand for the whole; as in the hieroglyphics of Horapollon, which represent a battle of two armies in array by two hands, one holding a shield and the other a bow: then putting the instrument of the thing, whether real or metaphorical, for the thing itself, as an eye and sceptre to represent a monarch, a ship and pilot the governor of the universe, &c.; and finally, by making one thing stand for or represent another, where their observations of nature or traditional superstitions led them to discover or imagine any resemblance: thus, the universe was designed by a serpent in a circle, whose variegated spots denoted the stars; and a man who had nobly surmounted his misfortunes was represented by the skin of the hyæna, because this was supposed to furnish an invulnerable defence in battle. The Chinese writing, he observes, was the next kind of improvement in the use of hieroglyphics. The Egyptians joined characteristic marks to images; the Chinese threw out the images and retained only the

the contracted marks, and from these marks proceeded letters. The general concurrence of different people in this method of recording their thoughts can never be supposed to be the effect of imitation, sinister views, or chance; but must be considered as the uniform voice of nature speaking to the rude conceptions of mankind: for not only the Chinese of the East, the Mexicans of the West, and the Egyptians of the South, but the Scythians likewise of the North, and the intermediate inhabitants of the earth, viz. the Indians, Phenicians, Ethiopians, &c. used the same way of writing by picture and hieroglyphic. He farther shews, that the several species of hieroglyphic writing took their rise from nature and necessity, and not from choice and artifice, by tracing at large the origin and progress of the art of speech. He proceeds to shew how in process of time the Egyptian hieroglyphics came to be employed for the vehicle of mystery. They used their hieroglyphics two ways; the one more simple, by putting the part for the whole, which was the curiologic hieroglyphic; and the other more artificial, by putting one thing of resembling qualities for another, called the trophic hieroglyphic: thus the moon was sometimes represented by a half-circle and sometimes by a cynocephalus.

HIEROGRAMMATEI, or HIEROGRAMMATISTS, [*ἱερογραμματῆς, i. e. holy registers,*] were an order of priests among the ancient Egyptians, who presided over religion and learning. They had the care of the hieroglyphics, and were the expositors of religious doctrines.

HIEROLOGY, [from *ἱερός, sacred,* and *λόγος, discourse,*] a discourse on sacred things. Among the Jews and Greeks it was used for the nuptial benediction.

HIEROMANCY, or HIEROMANTIA, [*ἱερομαντεία,*] in antiquity, that species of divination which predicted future events from observing the various things offered in sacrifice.

HIEROMENIA, in ancient Greek chronology, the month in which the Nemean games were celebrated, called also Boedromion.

HIEROMNEMON, [Gr. from *ἱερός, sacred,* and *μνημὼν, a remembrancer,*] an officer in the ancient Greek church, whose principal function was to stand behind the patriarch at the sacraments, ceremonies, &c. and shew him the prayers, psalms, &c. which he was to rehearse.

HIEROMNEMON, in Grecian antiquity, a delegate chosen by lot, and sent to the great council of the Amphictyons, to take care of what concerned religion.

HIEROPHANT, HIEROPHANTA, or HIEROPHANTES, [from *ἱερός, holy,* and *φαίνω, I appear,*] a priest among the Athenians; who was properly the chief person that officiated in the Eleusinia.

HIEROPHYLAX, [*ἱερός and φυλάξ,*] an officer in the Greek church, who was keeper of the holy utensils, vestments, &c. answering to the vestry-keeper in the church of England.

HIEROSCOPIA, [from *ἱερός, sacred,* and *σκοπεῖν, to view,*] a species of divination by inspecting the victims, the same with Hieromancy.

HIERTING, or JETTING, a sea-port town of Denmark, in N. Jutland, at the mouth of the Warde, with a good harbour: 22 miles N. W. of Ripen. Lon. 8. 22. E. Lat. 55. 29. N.

HIGH, in music, is sometimes used in the same sense with loud, and sometimes in the same sense with acute.

HIGH DUTCH is the German tongue in its greatest purity, as it is spoken at Misnia, &c.

HIGHAM FERRERS, a borough of Northamptonshire, 66 miles N. N. W. of London.

HIGHLANDS. See SCOTLAND.

HIGHLANDS, a mountainous country of New York, on the banks of Hudson's river, between 40 and 60 miles N. of New York city.

HIGHLANDER, a general appellation for the inhabitants of the mountainous parts of any country. In Britain, the name is appropriated to the inhabitants of the mountainous parts of Scotland, to the N. and N. W. including those of the Hebrides. They are a branch of the ancient Celts, and are undoubtedly the descendants of the first inhabitants of Britain, as appears from the many monuments of their language, still retained in the most ancient names of places in all parts of the island.

HIGHMORE, JOSEPH, Esq. an eminent painter, born in Lon-

don, June 13, 1692. He was articled as clerk to an attorney, in 1707; but so much against his inclination, that in three years he resolved to indulge his natural disposition to his favourite art; and employed his leisure-hours in designing, and in studying geometry, perspective architecture, and anatomy, without any instructors except books. By these exertions, he soon arrived at such perfection in his favourite art, that he painted many pictures which were not only valued highly in his own time, but are now the objects of admiration to painters. On the institution of the academy of painting, sculpture, &c. in London, in 1683, he was elected one of the professors. In 1734, he published in 4to. "A Critical Examination of those two Paintings (by Rubens) on the Ceiling of the Banqueting-house at Whitehall, in which Architecture is introduced, so far as relates to Perspective; together with the Discussion of a Question which has been the Subject of Debate among Painters:" in the solution of this question, he proved that Rubens and other great painters were mistaken in the practice, and Mr. Kirby and several others in the theory. And in volume 17th of the "Monthly Review, he animadverted (anonymously) on Mr. Kirby's unwarrantable treatment of Mr. Ware, and detected his errors, even when he exults in his own superior science. Mr. Highmore, painted many portraits, of which several have been engraved. In the historical branch, which was then much less cultivated than it is at present, we shall only mention Hagar and Ishmael, a present to the Foundling Hospital: The Good Samaritan; The Finding of Moses, purchased at his sale by general Lister; The Harlowe Family, as described in Clarissa, now in the possession of T. W. Payler, Esq. Clarissa herself; The Graces unveiling Nature, drawn by memory from Rubens: The Clementina of Grandison, and The Queen Mother of Edward IV. with her younger Son, &c. in Westminster Abbey; in the possession of his son. He was the author of various publications which were well received; but his most capital work was his Practice and Perspective, on the principles of Dr. Brook Taylor, &c. in one vol. 4to. 1763. This not only evinced his scientific knowledge of the subject, but, by its perspicuity, removed the only objection that can be made to the system of Dr. Taylor. His Epistle to an Eminent Painter, published in the Gent. Mag. for 1778, shews that his talents were by no means impaired at the age of 86. Indeed he retained them to the last, and had even strength and spirit sufficient to enable him to ride out daily on horseback the summer before he died. A strong constitution, habitual temperance, and constant attention to his health, in youth as well as in age, preserved his faculties to his 88th year, when he died March 3, 1780. He was interred in Canterbury cathedral, leaving one son, Anthony, educated in his own profession; and a daughter. His abilities as a painter appear in his works, which are much and justly admired. His tints, like those of Rubens and Vandyck, instead of being impaired, are improved by time, which some of them have now withstood above 60 years.

HIGHNESS. The kings of England and Spain had formerly no other title but that of highness; the first till the time of James I. and the second till that of Charles V. The petty princes of Italy began first to be complimented with this title in 1630. In France, the duke of Orleans assumed the title of royal highness in 1631, to distinguish himself from the other princes. The princes of the blood in England are each distinguished in the same way.

HIGH OPERATION, in surgery, a method of extracting the stone; thus called, because the stone was taken out at the upper part of the bladder, above the pubis. This operation is now, very properly, superseded by one much safer and more successful. See SURGERY.

HIGH PLACES, were eminences on which the heathens used to worship their gods, chosen for that purpose as being supposed to be nearer heaven, their constant residence. The Jews are frequently blamed for their attachment to high places, after the manner of the Gentiles; though their proseuchæ were frequently upon mountains with groves planted about them. Where high places are reprobated in scripture, therefore, we should understand them as abused and prostituted to idolatrous purposes. Before the temple was built, there was indeed nothing in the high places very contrary to the law, provided God only was adored there, and that no incense or victims were offered to idols. Under the judges they seem to have been tolerated; and Samuel offered sacrifices

in several places besides the tabernacle, where the ark was not present. Even in David's time, they sacrificed to the Lord at Shilo, Jerusalem, and Gibeon; but after the temple was built, and a place prepared for the fixed settlement of the ark, it was no more allowed, to sacrifice out of Jerusalem. Solomon, in the beginning of his reign, went a pilgrimage to Gibeon; but from that time we see no lawful sacrifices offered out of the temple.

HIGH-PRIEST. See **PONTIFEX** and **PRIEST**.

HIGHWAY, a free passage for the king's subjects; on which account it is called the king's highway, though the freehold of the soil belong to the owner of the land. Only those ways which lead from and to different towns or villages, and such as are cart-roads, communicating with the former, are properly called highways: the care of repairing them, &c. is reposed in commissioners and surveyors, who are empowered by various statutes to superintend them, and to see that no obstacles be laid in the roads.

HIGHWAYMEN, REWARDS FOR APPREHENDING. A reward of 40*l.* is given by the statute of 4 and 5 W. and M. to be paid within a month after conviction by the sheriff of the county; to which the statute 8 Geo. II. cap. 16, superadds 10*l.* to be paid by the hundred indemnified by such apprehension.

HIGHWORTH, a town of Wilts, 36 miles N. of Salisbury.

HILARIA, in antiquity, feasts celebrated annually, with great pomp and joy, by the Romans, on the 8 Kal. April, or 25th of March, in honour of Cybele. The Romans took this feast originally from the Greeks, who called it *ἡλικάρις*, *q. d.* ascensus; the eve of that day they spent in tears and lamentations, and thence denominated it *κατάβασις*, descensus. Afterwards, the Greeks took the name *ἡλάρια* from the Romans; as appears from Photius, in his extract of the life of the philosopher Isidore.

HILARY, St. a saint of the Roman Calendar, born at Arles, in 401. He succeeded Honoratus as bishop of Arles, and presided in the council at Rome in 441. He wrote, 1. Homilies, under the name of Eusebius of Emesa: 2. The Life of St. Honoratus: 3. Opuscula. He died in 449, aged 48.

HILARY TERM. See **TERM**.

HILD, in Elrick's grammar, is interpreted a lord or lady: so Hildebert is a noble lord; Mathild, an heroic lady. Gibson.

HILDBURGHAUSEN, a town in Franconia, 22 miles N. by W. of Cobourg, and 32 S. of Erfurt.

HILDESHEIM, a late princely bishopric of Germany, bounded on the N. and E. by the duchies of Lunenburg, Wolfenbützel, and Halberstadt, and on the S. and W. by Calenberg; and which extended 40 miles from E. to W. and 32 from N. to S.

HILDESHEIM, the capital of the above bishopric, seated on the Irneste, 17 miles S. S. E. of Hanover.

HILDESHEIM, or HILLESHEIM, a town of Germany, lately in the electorate of Treves, now annexed to France. It is 31 miles N. of Treves, and 36 W. of Coblenz.

HILLIA, in botany, a genus of the monogynia order, and hexandria class of plants. Calyx hexaphyllous; corolla cleft in six parts, very long; berry inferior, bilocular, polyspermous. It has two species, shrubs of Jamaica.

HILLSBOROUGH, a town of Ireland, in the county of Down, Ulster, 69 miles from Dublin.

HILLSBOROUGH, an island on the E. coast of Labrador. Lon. 61. 20. W. Lat. 57. 20. N.

HILLSBOROUGH, a fertile district of North Carolina, bounded on the E. by Halifax district, S. by Fayette, W. by Salisbury, and N. by Virginia; containing 7 counties, 46,477 citizens, and 13,506 slaves, in 1795.

HILLSBOROUGH, the capital of the above district.

HIMMALEH, a vast chain of mountains in Asia, which extends from Cabul along the N. of Hindostan, and appears to be the general boundary of Thibet. This ridge was by the ancients named Imaus, and the Indian Caucasus. The natives now call it Hindoo-Ko, (*i. e.* the Indian mountains) as well as Himmaleh; which last is a Sanscrit word, signifying snowy; its summit being covered with snow.

HIN, [*ḥin*] a measure of liquids among the Jews, containing about ten pints. It is the sixth part of an ephah.

HINCKLEY, a town of Leicestershire, 91 miles N. N. W. of London.

HIND, a female stag of the third year. See **CERVUS**.

HIND-CASTLE, in sea-language, the elevation of the stern over the last deck, where the officer's cabins and places of assembly are.

HINDECK, a town of the Helvetic republic, in the canton of Bern, 15 miles S. E. of Interlaken.

HINDELBANK, a town of the Helvetic republic, in Bern, 9 miles N. N. E. of Bern.

HINDELOPEN, or HINLOPEN, a seaport of Batavia, in the department of the Eems, and late province of Friesland, on the Zuider Zee.

HINDIA, a district of Hindoostan, in the province of Candish.

HINDIA, a town in the above district, on the Nerbudda, 6 miles E. S. E. of Indore, and 90 N. N. E. of Burhampour. Lon. 77. 10. E. Lat. 22. 35. N.

HINDON, a small town of Wiltshire. Lon. 2. 14. W. Lat. 51. 12. N.

HINDOO KHO, or INDIAN CAUCASUS, a part of a long ridge of mountains in Asia, which separate Cabul from Balk.

HINDOOS, or GENTOOS, the inhabitants of that part of India known by the names of Hindoostan, Hindostan, India, or the Mogul's empire, who profess the religion of the Bramins. From the earliest period of history, these people seem to have maintained the same religion, laws, and customs, which they do at this day: and indeed, they and the Chinese are examples of perseverance in these respects altogether unknown in the western world. But the reason is obvious. The arbitrary form of both governments obliges the people to believe, or profess to believe, as their fathers did. In the time of Diodorus Siculus they are said to have been divided into seven casts or tribes; but the intercourse betwixt Europe and India was in his time so small, that we may well suppose the historian to have been mistaken, and that the same tenacity for which they are so remarkable in other respects has manifested itself also in this. At present they are divided only into four tribes; 1. The Bramin; 2. The Khatri, or Cheltee; 3. The Bhyse, or Bice; and, 4. The Soodera. See **GENTOOS**. All these have distinct and separate offices, and cannot, according to their laws, intermingle with each other; but for certain offences they are subject to the loss of their cast, which is reckoned the highest punishment they can suffer; and hence is formed a kind of fifth cast named Pariars on the coast of Coromandel, but in the Sanscrit language, Chandalas. These are esteemed the dregs of the people, and are never employed but in the meanest offices. There is besides a general division which pervades the four casts indiscriminately; and which is taken from the worship of their gods Vishnou and Sheevah; the worshippers of the former being named Vishnou-bukht; of the latter, Sheevah-bukht. Of these four casts the Bramins are accounted the principal in every respect; see **BRAMINS**, and all the laws have such an evident partiality towards them, as cannot but induce us to suppose, that they have had the principal hand in framing them. They are not, however, allowed to assume the sovereignty; the religious ceremonies and the instruction of the people being their peculiar province. They alone are allowed to read the Veda, or sacred books; the Khatries being only allowed to hear them read; while the other two casts can only read the Sastras, or commentaries upon them. As for the poor Chandalas, they dare not enter a temple, or be present at any religious ceremony. In point of precedence the Bramins claim a superiority even to the princes; the latter being chosen out of the Khatri or second cast. A rajah will receive with respect the food that is prepared by a bramini, but the latter will eat nothing that has been prepared by any member of an inferior cast. The punishment of a bramini for any crime is much milder than if he had belonged to another tribe; and the greatest crime that can be committed is the murder of a bramini. No magistrate must desire the death of one of these sacred persons, or cut off one of his limbs. They must be readily admitted into the presence even of princes whenever they please: when passengers in a boat, they must be the first to enter and go out; and the waterman must besides carry them for nothing; every one who meets them on the road being likewise obliged to give place to them. All the priests are chosen from among this order, such as are not admitted to the sacerdotal function being employed as secretaries and accountants. These can never afterwards become priests,

priests, but continue to be greatly revered by the other cast. The Khatry, or second cast, are those from among whom the sovereigns are chosen. The Blyse, or Banians, who constitute the third cast, have the charge of commercial affairs; see BANIANs, and the Soodera, or fourth cast, the most numerous of all, comprehend the labourers and artisans. These last are divided into as many classes as there are followers of different arts; all the children being invariably brought up to the profession of their fathers, and it being absolutely unlawful for them ever to alter it afterwards. No Hindoo is allowed to quit the cast in which he was born upon any account.

HINDOOSTAN, HINDUSTAN, or INDOSTAN, a celebrated and extensive country of Asia, bounded on the N. by Great and little Thibet; on the S. by the hither peninsula of India, part of the Indian Sea, and Bay of Bengal; on the W. by Persia; and on the E. by Thibet and the farther peninsula. It is situated between 84° and 102° of lon. E. and between 21° and 36° of lat. N: being about 1204 miles long, and 969 broad; though in some places much less. This country was in early times distinguished among the Greeks by the name of India, the most probable derivation of which is from the river Indus, though others derive it from Hind the Persian name. We are assured by Mr. Wilkins, that no such words as Hindoo or Hindoostan exist in the Sanscrit or learned language of the country; in which it is named Bharata, a word totally unknown to Europeans. Towards the north, Hindoostan is very cold and barren; but towards the south, very hot, and fertile in corn, rice, fruits, and other vegetables. The northern provinces are very mountainous and sandy; while the southern are for the most part level, and well watered with several rivers. The weather and seasons are, in general, very regular; the winds blowing constantly for six months from the N. with very little variation. April, May, and the beginning of June, till the rains fall, are so extremely hot, that the reflexion from the ground is apt to blister the face; and but for the breeze, or small gale of wind, which blows every day, there would be no living in that country for people bred in northern climates; for, excepting in the rainy season, the coldest day is hotter there at noon, than the hottest day in England. However, very surprising changes of heat and cold sometimes happen within a few hours; so that a stifling hot day is succeeded by a night cold enough to produce a thin ice on the water, and that night by a noon as scorching as the preceding. The most remarkable mountains are those on the W. separating it from Persia, called, in general, Soleyman Kay, or the mountains of Soleyman, of a vast height as well as breadth, and only passable in certain places, through which roads have been made for the sake of commerce. The mountains on the N. are called Nagrakut, Hima, or Mûs Tâg, which has an affinity with Imaus, and by other names, which are given also in common to the mountains on each side, separating Hindostan from Thibet. The principal rivers of Hindoostan are the INDUS, GANGES, and BURRAMPOOTER, which see. Hindoostan is very rich in every kind of productions, whether fossil, vegetable, or animal. Besides other precious stones, there is a diamond-mine at the town of Soumelpur in Bengal. Quarries of Theban stone are so plentiful in the Mogul's empire, that there are both mosques and pagods built entirely of it. Travellers tell us, there are mines of lead, iron, and copper, and even silver; but those of the last, if there be any, need not be opened, for the bullion of all nations is sunk in this empire, which takes nothing else in exchange for its commodities, and prohibits the exporting it again. The people till the ground with oxen and foot-ploughs, sowing in May and the beginning of June, that all may be over before the rains, and reaping in Nov. and Dec. which with them are the most temperate months in the year. The land is no where inclosed, excepting a little near towns and villages. The grass is never mowed to make hay, but cut off the ground, either green or withered, as they have occasion to use it. Wheat, rice, barley, and other grain, grow here in plenty, and are very good. The country abounds no less in fruits, as pomegranates, citrons, grapes, almonds, and cocoa-nuts; plums, plantanes, mangos, ananas, or pine-apples, lemons, oranges, and many other kinds of fruit-trees peculiar to the country. But the most valuable trees are the cotton and mulberry, on account of the wealth they bring the natives from the manufacture of calicoes and silks. They plant abundance of sugar-canes here, as well as tobacco; but the latter is not so rich and strong as that of America, as they

know not how to cure and order it. There is great variety of quadrupeds in this country, both wild and tame; among the former are elephants, rhinoceroses, lions, tigers, leopards, wolves, jackals, and the like. This country is also much infested with reptiles and insects; some of a noxious kind, as scorpions, snakes, and rats; but the lizards, which are of a green colour, are not hurtful. Snakes and serpents, we are told, are sometimes employed to dispatch criminals, especially such as have been guilty of very atrocious crimes, that kind of death being attended with the most grievous torture. The most troublesome insects in this hot country are flies, musketoes, and chinchies or bugs.

HINDOW, a territory of Hindoostan, bounded by Delhi and Agra on the N. and E.; and by Asimer on the S. and W.

HINDOW, the capital of the above territory. The people boast their descent from the original inhabitants of India. Lon. $78. 5. E.$ Lat. $26. 50. N.$

HINGHAM, a market-town of Norfolk, 12 miles S. W. of Norwich, and 97 N. E. of London. Lon. $1. 4. E.$ Lat. $52. 43. N.$

HING-HOA, a city of China of the first rank, in the province of Fo-kien, near the sea-coast, 900 miles S. of Pekin.

HINKAN, a chain of mountains in Chinese Tartary.

HIO, a town of Sweden, in W. Gothland, seated on the Lake Wetter, 145 miles S. W. of Stockholm. Lon. $14. 0. E.$ Lat. $57. 53. N.$

HIP, in the materia medica, the fruit of the dog-rose or wild brier. See ROSA. It contains an acidulous, yet sweetish pulp; with a rough prickly matter inclosing the seeds, from which the pulp ought to be carefully separated before it be taken internally. The conserve is the only officinal preparation of this fruit, which possesses any medical virtues: it is very pleasant, but is merely used by the apothecaries as a vehicle for other remedies. The Edinburgh College have omitted it.

Hip, in architecture, the angle formed by two parts of the roof when it rises outwards. Hips are also those pieces of timber which are placed at the corners of a roof. They are much longer than rafters, on account of their oblique position.

HIPPARCHIA, a celebrated lady born at Maronea in Thrace, in the time of Alexander the Great. Her attachment to learning and philosophy was so great, that, having attended the lectures of Crates the Cynic, she fell in love with him, and resolved to marry him, though he was both old and ugly, and though she was courted by many handsome young men, distinguished by their rank and riches. Crates himself was prevailed upon by her friends, to try to dissuade her from her singular choice, which he did by displaying his poverty, his cloak, his bag, and his crooked back, but all in vain. At last he told her, she could not be his wife, unless she resolved to live as he did. This she cheerfully agreed to, assumed the habit of the order, and accompanied him every where to public entertainments, &c. which was not customary with the Grecian ladies. She wrote several tragedies, "Philosophical Hypotheses," and "Reasonings and Questions proposed to Theodorus the Atheist; but none of her works are extant.

HIPPARCHUS, an eminent astronomer, born at Nice in Bithynia, who flourished between the 154th and 163d Olympiads. His commentary upon Aratus's Phenomena is still extant. Rhault is very much mistaken when he asserted, that this astronomer was not acquainted with the particular motion of the fixed stars from W. to E. by which their longitude changes. By foretelling eclipses, he taught mankind not to be frightened at them, and that even the gods were bound by laws. Pliny, who tells this, admires him for making a review of all the stars; by which his descendants would be enabled to discover whether they are born or die, whether they change their places, and whether they increase and decrease.

HIPPIA, in botany, a genus of the polygamia necessaria order, and syngenesia class of plants. Receptacle naked; down none; seeds naked, with broad margins; calyx hemispheric, subimbricate, corollets of ten rays, obscure, and rather cleft into three. It has three species.

HIPPOBOSCA, the HORSE-FLY; in zoology, a genus of insects of the order diptera. Beak two-valved, cylindrical, obtuse, hanging; feet armed with several claws; body hard and flat. There are five species, distinguished by their wings, &c. The most remarkable is the H. Equina, the pest of horses and cows. This insect is broad, flat, shining, and as it were scaly. Its head, thorax,

horax, and abdomen, are yellow, undulated with brown; and the legs are intersected with yellow and brown. The wings, crossed one over the other, exceed the length of the body by above one half; they are transparent, tinged with a little yellow towards their outward edge, and have a spot near that edge of a brown colour. These insects are very difficult to be killed, on account of the hard crustaceous shell which covers them; and they fix so close and fast to the poor animals with their claws, that they cannot rub or bite them off without wounding themselves.

HIPPOCASTANUM, the common horse-chesnut. See *Æsculus*.

HIPPOCENTAURS, [from *ἵππος*, a horse, *κέντρον*, I spur, and *ταύρος*, a bull,] in antiquity, a fabulous animal, half man and half horse. What gave rise to the fable of hippocentaurs, was this. The Thessalians are said to have been the first inventors of the art of breaking horses; and being first seen on horseback, they seemed but one body with the horses; whence the origin of the fable.

HIPPOCRAS, [*hipocras* French; *quasi vinum Hippocratis*, Lat.] a medicated wine. It is composed of wine, with spices and other ingredients; and is much used in France, as a cordial after meals. There are various kinds of it, according to the kind of wine and other ingredients used; as white, red, claret, and strawberry hippocras without wine; cyder hippocras, &c. The London Dispensatory directs it to be made of cloves, ginger, cinnamon and nutmegs, grossly powdered, and infused in canary with sugar: to this infusion may be added, milk, a lemon, and some slips of rosemary, and the whole strained through flannel. It is recommended as a cordial, and in paralytic and nervous cases.

HIPPOCRATEA, in botany, a genus of the monogynia order, and tetrandria class of plants. Calyx five-parted, petals five, capsules three, obcordate, or elliptic. It has two species, *H. comosa*, and *H. volubilis*.

HIPPOCRATES, the greatest physician of antiquity, was born in the island of Coos, in the 80th Olympiad, and flourished during the Peloponnesian war. He was the first on record, who laid down precepts concerning physic; and, according to his biographer Soranus was descended from Hercules and Æsculapius. He was first a pupil of his father Heraclides, then of Herodicus, then of Gorgias of Leontium the orator, and according to some, of Democritus of Abdera. After being instructed in physic and the liberal arts, and losing his parents, he left Coos, and practised physic all over Greece; where he was so much admired for his skill, that he was publicly sent for, by Perdiccas king of Macedonia, who was then thought to be consumptive. But Hippocrates pronounced the disease to be entirely mental. For upon the death of his father Alexander, Perdiccas fell in love with Philips, his father's mistress; which Hippocrates discerning by the great change her presence always wrought upon him, a cure was soon effected. Being entreated by the people of Abdera to come and cure Democritus of a supposed madness, he went; but, upon his arrival, he declared that Democritus was the only wise man among them. He heard many lectures, and learned much philosophy from him; which made Celsus and others imagine, that Hippocrates was the disciple of Democritus, though it is probable they never saw each other till this interview. Hippocrates had also public invitations to other countries. Thus, when a plague invaded the Illyrians and Pæonians, the kings of those countries begged him to come to their relief: he refused to go; but predicted that the distemper would come to Athens; and, foretelling what would happen, applied himself to take care of the city and the students. The Athenians conferred on him great honours, and voted a public maintenance for him and his family. He died B. C. 361. His memory is still venerated in his native island, and the inhabitants shew with pride a house in which they say he resided. The best editions of his works are those of Geneva, fol. 1657; Amsterdam, 2 vols. 8vo, 1665; and Vienna, 2 vols. folio, 1740.

HIPPOCRATES'S SLEEVE, a woollen bag, made by joining the two opposite angles of a square piece of flannel, used to strain syrups and decoctions for clarification.

HIPPOCREPIS, COMMON HORSE-SHOE VETCH; in botany, a genus of the decandria order, and diadelphia class of plants; natural order, Papilionaceæ. Legume compressed, several times emarginate along one of the sutures, curved. There are five species. These are small herbaceous plants; with unequally-pinnate leaves and stipules; peduncles axillary, and terminating, one

or many-flowered, in umbels; corollas mostly yellow. Natives of the South of Europe.

HIPPODROME, or **HIPPODROMUS**, [from *ἵππος*, a horse, and *δρομος*, a course,] in antiquity, a course wherein chariot and horse races were performed, and horses exercised.

HIPPOMANE, the **MANCHINEEL-TREE**, a genus of the monadelphia order, and monœcia class of plants; natural order, Tricocceæ. See Plate LXV. Male, ament; perianthium bifid; corolla none; female, perianthium bifid; corolla none; stigma three-parted; drupe or capsule three-grained. There are three species. *H. mancinella*, manchineel-tree, is a very large tree in the West Indies, almost equalling the oak in size. The first accounts of this tree stated that it was dangerous to sit or lie under it, and that the rain which falls from the leaves will raise blisters in the skin. However professor Jacquin informs us, that he and his companions reposed upwards of three hours under a manchineel-tree, without receiving any injury; and that rain dropping from the leaves upon them was perfectly innocent. It is dangerous to eat of the fruit, which resembles crab-apples; it occasions vomiting, and a burning heat in the mouth, throat, and stomach, for many hours after. The juice of the buds of the white cedar is esteemed an antidote to this poison, and is generally used with success.

HIPPOMANES, [from *ἵππος*, a horse, and *μανία*, madness,] a sort of poison famous among the ancients as an ingredient in amorous philters or love-charms. Virgil, and after him Servius and Columella, describe it as a poisonous matter tricking from the pudendum of a mare when proud, or longing for the horse. At the end of M. Bayle's Dictionary is a very learned dissertation on the hippomanes, and all its virtues real and pretended.

HIPPONA, [from *ἵππος*, a horse,] or **EPONA**, in ancient mythology, the goddess of horses.

HIPPOPHAE, **SEA-BUCKTHORN**; a genus of the tetrandria order, and diœcia class of plants; natural order, Calycifloræ. Male, calyx two-parted; corolla none; Female, calyx bifid; corolla none; style one; berry one-seeded. It has two species, viz. *H. rhamnoides*, common sea-buckthorn, and *H. canadensis*, Canadian sea-buckthorn.

HIPPOPHAGI, in ancient geography, a people of Scythia, so called from their living on horseflesh; the fare at this day of the Tartars their descendants. Also, a people of Persia.

HIPPOPODES, or **HIPPOPODIÆ**, [from *ἵππος*, a horse, and *πῶς*, a foot,] in ancient geography, an appellation, given to a certain people situated on the banks of the Scythian sea, who were supposed to have had horses feet.

HIPPOPOTAMUS, [*ἵππος* and *ποταμός*,] the **RIVER-HORSE**, a genus of quadrupeds of the order belluæ. The generic character is, the front-teeth of the upper jaw four, placed in pairs; those of the lower jaw prominent, and the intermediate ones protruded forward; canine teeth single, obliquely truncated; teats only two, placed near the groin. It is a native of the warmer regions of the globe, and is chiefly found in the middle parts of Africa, inhabiting large rivers, and especially such as run through countries overshadowed by large forests; walking about at the bottom, and raising itself at intervals to the surface, for the purpose of respiration. By night it quits its watery residence, to graze in the neighbouring plains, devouring great quantities of herbage, and with its vast teeth destroying the more tender kind of trees and other vegetables. It is sometimes seen even in the sea, at some distance from the mouths of rivers, but this is supposed to be merely for the purpose of exercise; for it will not even drink salt-water, and does not prey on fish, or indeed live on any kind of animal food. The general size of the hippopotamus seems to be nearly equal to that of the rhinoceros, and it is sometimes even superior. Its form is highly uncouth; the body being extremely large, fat, and round; the legs very short and thick; the head very large; the mouth extremely wide, and the teeth of vast strength and size, more particularly the tusks or canine teeth of the lower jaw, which are of a curved form; they sometimes measure more than two feet in length, and weigh upwards of six pounds each. The whole animal is covered with short hair, which is more thinly set on the under parts than on the upper. The hippopotamus when just emerged from the water appears of a palish-brown, or mouse-colour, with a bluish or slate-coloured cast on the upper parts; and the belly is flesh-coloured, the skin appearing through the hair. When perfectly dry the colour is an obscure brown, with

out any of the bluish cast. The skin is most excessively tough and strong, except on the belly, where it is considerably softer. Its voice is a peculiar kind of interrupted roar, between that of a bull and the braying of an elephant. When on land it moves in a somewhat slow and awkward manner; but if pursued, can run with considerable speed, and directly plunging into the water sinks to the bottom, and pursues its progress beneath. It is observed to be extremely cautious of making its appearance by day, especially in such places as are much frequented by mankind, scarcely lifting its nose above the surface while breathing; but it is fearless in rivers, which run through unfrequented regions, where it is occasionally seen to rush out of the water with sudden impetuosity, trampling down every thing in its way; and at such times is, of course, highly dangerous. It is, however, naturally of a harmless disposition; not attacking other animals, but merely committing havoc in plantations of maize, rice, sugar-canes, &c. and destroying the roots of trees, by loosening them with its vast teeth. It is capable, notwithstanding its great bulk, of swimming very swiftly. See Plate LXIX. The hippopotamus was known to the Romans. Scaurus treated the people with the sight of five crocodiles and one hippopotamus during his ædileship, and exhibited them in a temporary lake. Augustus produced one at his triumph over Cleopatra. This animal appears to be the Behemoth of Job; who admirably describes its manner, its food, and its haunts: chap. xl. verse 15.—24. Ver. 15th, the learned Bochart observes, implies the locality of its situation, being an inhabitant of the Nile, in the neighbourhood of Uz, the land of Job. The 16th describes its great strength; and the 18th the peculiar hardness of its bones. The 21st and 22d indicate its residence amidst the vast reeds of the Nile and other African rivers overshadowed with thick forests. The 23d the characteristic wideness of its mouth; which is hyperbolically described as large enough to exhaust the Jordan. An entertaining account of the hippopotamus is given in Sparman's Voyage to the Cape of Good Hope, where these animals are called sea-cows.

HIPPURIS, *MARE'S-TAIL*; a genus of the monogynia order, and monandria class of plants; natural order, Inundatæ. There is no calyx; petals a two-lobed rim; stigma simple; seed one. It has three species.

HIPPUS, an affection of the eyes, that makes them represent objects in the like kind of motion as when on horseback.

HIR, a town of Persia, in the province of Kirman.

HIRÆA, in botany, a genus of the trigynia order, and decandria class of plants. Calyx pentaphyllous; petals roundish and unguiculated; there are three bilabiated seeds.

HIRCH-HORN, a town in the Lower Rhine, seven miles E. of Heidelberg.

HIRCUS, in astronomy, a fixed star of the first magnitude, called also Capella.

HIRCUS is also used for a comet, encompassed with a mane, seemingly hairy.

HIRE, **PHILIP DE LA**, an eminent French mathematician and astronomer, born at Paris in 1640. His father was painter in ordinary to the king, and designed him for the same profession: but he devoted himself to mathematical studies, and was nominated together with M. Picard to make the necessary observations for a new map of France, by the directions of M. Colbert. In 1683, he was employed in continuing the famous meridian-line begun by M. Picard; and was next engaged in constructing the grand aqueducts projected by Lewis XIV. He died in 1718, after having written a great number of works, besides several occasional papers dispersed in Journals, and in Memoirs of the Academy of Sciences.

HIRPINI, in ancient geography, a people of Italy, next to the Samnites, to the S. E. and descendants from them; situated to the N. of the Picentini, and to the W. of the Apuli, having on the N. the Apennine and a part of Samnium. The name is from *Hirpus*, a term denoting a wolf in their language; either because under the conduct of this animal the colony was led and settled, according to Strabo; or because, like that prowling animal, they lived on plunder, according to Servius.

HIRTELLA, in botany, a genus of the monogynia order, and pentandria class of plants. Petals five; filaments very long, persisting, spiral; berry monospermous; style, lateral. It has three species.

HIRUDO, the *LEECH*; a genus of insects of the order vermes intestina. The body moves either forward or backward. There are seventeen species, principally distinguished by their colour. The most remarkable are the following:

H. GEOMETRA, the *GEOMETRICAL LEECH*, grows to an inch and a half in length; and has a smooth and glossy skin of a dusky brown colour, but in some seasons greenish-spotted with white. When in motion, its back is elevated into a kind of ridge; and it then appears as if measuring the space it passed over like a compass, whence its name. Its tail is remarkably broad; and it holds as firmly by it as by the head. It is common on stones in shallow running waters; and is often found on trouts and other fish after spawning-time.

H. MEDICINALIS, the *MEDICINAL LEECH*, the form of which is well known, grows to the length of two or three inches. The body is of a blackish brown colour, marked on the back with six yellow spots, and edged with a yellow line on each side; but both the spots and the lines grow faint, and almost disappear, at some seasons. The head is smaller than the tail, which fixes itself very firmly to anything the creature pleases. It is viviparous, and produces but one young one at a time, which is in July. It is an inhabitant of clear running waters, and is well known for its use in bleeding. The leech's head is armed with a sharp instrument that makes three wounds at once. They are three sharp tubercles, strong enough to cut through the skin of a man, or even of an ox or horse. The mouth is as it were the body of the pump, and the tongue or fleshy nipple the sucker; by the working of this piece of mechanism, the blood is made to rise up to the conduit which conveys it to the animal's stomach, which is a membranaceous skin, divided into 24 small cells. The blood which is sucked out is there preserved for several months almost without coagulating, and proves a store of provision to the animal. The nutritious parts, pure and already digested by animals, require not to be disengaged from the heterogeneous substances: nor indeed is there any thing like an anus discoverable in the leech; mere transpiration seems to be all that it performs, the matter fixing on the surface of its body, and afterwards coming off in small threads. Of this an experiment may be tried by putting a leech into oil, where it keeps alive for several days; upon being taken out and put into water, there appears to loosen from its body a kind of slough shaped like the creature's body. The organ of respiration seems to be situated in the mouth; for if, like an insect, it drew its breath through vent-holes, it would not subsist in oil, as by it they would be stopped up. This is the only species that is used for local bleedings. It may be applied with great safety and advantage, especially for obstinate head-aches arising from fullness of blood, as well as in many cases of external inflammation, with a view to extract the thick and superfluous humour with which the vessels are overcharged. If the leech will not readily fix itself, a few drops of milk may be rubbed on the spot where it is to perform the operation; or a little blood may be drawn, by making a slight puncture, after which it will immediately settle. When employed for relieving the piles, or to extract blood from the gums, it is requisite to secure the insect with a piece of rush, to prevent it either from creeping into the anus or gullet, in which cases it would occasion great distress, in the stomach or intestines. To induce the leech to quit its hold when it adheres longer than required, oil of tartar, volatile alkali, pepper, or acids, are occasionally employed; though a little common salt, strewed on its head, will answer the same purpose. On the contrary, if it be intended to draw a larger quantity of blood, the tail of the leech should be cut off; in consequence of which it continues to draw blood, in order to repair the loss it has sustained. The discharge occasioned by the puncture of a leech, is easily stopped with brandy, vinegar, &c. or may be kept open by applying warm fomentations.

H. MURICATA, the *MURICATED LEECH*, has a taper body, rounded at the greater extremity, and furnished with two small tentacula, or horns, strongly annulated and rugged upon the rings, the tail dilated. It inhabits the Atlantic Ocean, and is by the fishermen called the sea-leech. It adheres to fish, and generally leaves a black mark on the spot.

H. SANGUI-SUGA, the *HORSE-LEECH*, is of a larger size than the medicinal leech. Its skin is smooth and glossy; the body is depressed; the back is dusky; and the belly is of a yellowish green,

green, having a yellow lateral margin. It inhabits stagnant waters. At Ceylon, travellers who walk bare-legged are molested by the great numbers of leeches concealed under the grass.

HIRUNDO, in ornithology, a genus of birds of the order, *passeres*. See Plate LVIII. Bill short, depressed at the base, small at the point, and a little bending; nostrils open; tongue short, broad, and cleft; wings long; legs short; tail, in general, forked. There are thirty-seven species. The birds of this genus, subsist chiefly on the insects which are known to abound in the air, where they are almost constantly on the wing, and seize their prey with admirable dexterity; and for this purpose they are furnished with a most extraordinary power of distending their jaws. The service they perform to man by their assiduity in this work of destruction is not lightly to be appreciated, and those who observe the crowded population of the atmosphere through the beams of a summer-evening, will easily be led to believe, that, but for the interception of incalculable myriads of insects by these birds, the annoyance of man by these minute animals would be highly distressing, and perhaps almost intolerable. Each species of *hirundo* drinks as it flies along, sipping the surface of the water; but the swallow alone, in general, washes on the wing, by dropping into a pool for many times together: in very hot weather house-martins and bank-martins dip and wash a little. The swallow is a delicate songster, and in soft sunny weather sings both perching and flying; on trees in a kind of concert, and on chimney-tops. Horsemen on wide downs are often closely attended by a little party of swallows for miles together, which plays before and behind them, sweeping around, and collecting all the sculking insects that are roused by the trampling of the horses' feet: when the wind blows hard, without this expedient, they are forced to settle to pick up their lurking prey. Thus the swallow is very useful to mankind in defending him from the personal and domestic annoyance of flies and gnats; and, what is of infinitely more consequence, they keep down the numbers of our minute enemies, who either in the grub or winged state, would otherwise render the labours of the husbandman fruitless. Since then swallows are guardians of our corn, they should every where be protected by the same popular veneration which in Egypt defend the ibis, and the stork in Holland. We more frequently hear of unproductive harvests on the Continent than in this country; and it is well known that swallows are caught and sold as food in the markets of Spain, France, and Italy. In England we are not driven to such resources to furnish our tables. But what apology can be made for those, and many there are, whose education and rank should have taught them more innocent amusements, who wantonly murder swallows, under the idle pretence of improving their skill in shooting game? Setting aside the cruelty of starving whole nests of young by killing the dam; those who follow this barbarous diversion would do well to reflect, that by every swallow they kill, they assist blasts, mildews, and vermin, in causing a scarcity of bread. Every lord of a manor should restrain his game-keeper from this execrable practice; nor should he permit any person to sport on his lands who does not refrain from it. These birds disappear during the winter-season to account for which various opinions have been entertained. Some suppose that they lie torpid, in the banks of rivers, or in decayed trees, or in ruined edifices or vaults; and others, that they retire for the winter from the air to the water, lying in immense clusters, like swarms of bees, at the bottoms of rivers. Particular facts are on record, by respectable testimony, in favour of both these hypotheses. It is also attested, on similar authority, that migrations of these birds actually take place. They have frequently been seen by mariners at a vast distance from land, and in very numerous flocks; and have occasionally converted the rigging and yards of vessels into resting places, which have most conveniently relieved their long and wearisome flight. This last opinion is most generally received, and appears the most reasonable.

H. ESCULENTA, the **EDIBLE SWALLOW**, according to Buffon, is less than the wren, and only two inches and a quarter in length. The bill is black; the upper parts of the body are brown, the under whitish; the tail is forked, and each feather of it tipped with white; the legs are brown. The most curious part of the natural history of this bird consists in the nest, which is composed of such materials as render it not only edible, but one of the greatest dainties of the Asiatic epicures. These nests are found in vast num-

bers, in certain caverns, in various isles in the Soolo Archipelago, situated between lon. 117° and 120° E. and lat. 5° and 7° N. in the caverns of which the nests are found fixed to the stones in astonishing numbers. They are also found in amazing quantities on a small island called Toc, in the straits of Sunda; the caverns of which are lined with the nests: but no where in greater abundance than about Croee; near the S. end. They are common from Java to Cochinchina on the N. and from the point of Sumatra W. to New Guinea on the E. where the sea is said to be covered with a viscous substance like half-melted glue, which the bird is supposed either to take up from the surface with its bill during flight, or to pick it from the rocks when left there by the waves. Of these nests, it is said, the Dutch alone export from Batavia 1000 pickles, upwards of 1300lb. English weight, every year, which are brought from the isles of Cochinchina, and those lying to the E. of them.

H. RUSTICA, the **COMMON** or **CHIMNEY SWALLOW**, is distinguished from all the other species by the superior forkiness of its tail, and by the red spot on the forehead under the chin. The crown of the head, the whole upper part of the body, and the coverts of the wings, are black, glossed with a rich purplish blue, and most resplendent in the male: the breast and belly white, and in the male tinged with red: the tail is black; the two middle-feathers are plain, the others marked transversely near the ends with a white spot: the exterior feathers of the tail are much longer in the male than in the female. This species is the first comer of all the British *hirundines*: and appears in general on or about the 13th of April, though now and then a straggler is seen much earlier. This species, though called the chimney-swallow, by no means builds altogether in chimneys, but often in barns and out-houses against the rafters; as Virgil long ago remarked. (*Georg. lib. iv. 306.*) In Sweden she builds in barns, and is called *ladu swala*, the barn-swallow. In the warmer parts of Europe, where there are no chimneys to houses except they are English built, she constructs her nest in porches, gate-ways, galleries, and open halls. But in general, with us, this species breeds in chimneys; and haunts those stacks where there is a constant fire, for the sake of warmth; generally preferring one adjoining to the kitchen, and disregarding the perpetual smoke of that funnel. Five or six or more feet down the chimney, does this little bird begin to form her nest about the middle of May, which consists, like that of the house-martin, of a crust or shell composed of dirt or mud, mixed with short pieces of straw to render it tough and permanent; with this difference, that, whereas the shell of the martin is nearly hemispheric, that of the swallow is open at the top, and like half a deep dish. This nest is lined with fine grasses, which are often collected as they float in the air. Wonderful is the address (*Mr. White* observes) which this adroit bird shews all day long in ascending and descending through so narrow a pass. When hovering over the mouth of the funnel, the vibration of her wings acting on the confined air occasions a rumbling noise like thunder. It is probable that the dam submits to this inconvenient situation, so low in the shaft, in order to secure her brood from rapacious birds, and particularly from owls, which frequently fall down chimneys, perhaps in attempting to get at these nestlings. This bird lays from four to six white eggs, dotted with red specks; and brings out her first brood about the last week in June, or the first in July. The progressive method by which the young are introduced into life is very curious: first, they emerge from the shaft with difficulty enough, and often fall down into the room below: for a day or so they are fed on the chimney-top, and are then conducted to the dead leafless bough of some tree, where, sitting in a row, they are attended with great assiduity, and may then be called perchers. In a day or two more they become flyers, but are still unable to take their own food: therefore they play about near the place where the dams are hawking for flies; and, when a mouthful is collected, at a certain signal given, the dam and the nestling advance, rising towards each other, and meeting at an angle; the young one all the while uttering such a little quick note of gratitude and complacency, that one must have paid very little regard to the wonders of Nature, who has not remarked this feat. The dam betakes herself immediately to the rearing of a second brood, as soon as she is disengaged from her first; which she at once associates with the first broods of house-martins; and with them congregates, clustering on sunny roofs, towers, and trees. She brings out her second brood towards the middle

middle and end of August. All the summer long is the swallow a most instructive pattern of unwearied industry and affection; for from morning to night, while there is a family to be supported, she spends the whole in skimming close to the ground, and exerting the most sudden turns and quick evolutions. Avenues, and long walks under hedges, and pasture-fields, and mown meadows where cattle graze, are her delight, especially if trees be interspersed; because in such spots insects most abound. When a fly is taken, a smart snap from her bill is heard, resembling the noise at the shutting of a watch-case; but the motion of the mandibles is too quick for the eye. The swallow, probably the male bird, is the excubitor to house-martins and other little birds, announcing the approach of birds of prey. For as soon as an hawk appears, with a shrill alarming note he calls all the swallows and martins about him; who pursue in a body, and buffet and strike their enemy till they have driven him from the village, darting down from above on his back, and rising in a perpendicular line in perfect security. This bird will sound also the alarm, and strike at cats when they climb on the roofs of houses, or otherwise approach the nests. This species feeds much on little coleoptera, as well as on gnats and flies; and often settles on dug ground, or paths, for gravel to grind and digest its food. Mr. White informs us, that before they depart, for some weeks, they all forsake houses and chimneys, and roost in trees; and usually withdraw about the beginning of October; though some few stragglers may be seen at all times the first week in November. Mr. Pennant says, that for a few days previous to their departure, they assemble in vast stocks on house-tops, churches, and trees, from whence they take their flight. They are supposed to take up their winter-quarters in Senegal and parts adjacent; and seem to possess in turn the whole of the old continent, being known from Norway to the Cape of Good Hope on the one hand, and from Kamtschatka to India and Japan on the other. They are also found in all parts of North America, migrating N. and S. as with us. See Plate LVIII.

H. URBICA, the MARTIN, is inferior in size to the chimney-swallow, and its tail much less forked. The head and upper part of the body, except the rump, are black glossed with blue: the breast, belly, and rump, are white: the feet are covered with a short white down. This is the second of the swallow-kind that appears in our country; and of its manners and economy we have the following curious account in the Rev. Mr. White's *Natural History of Selborne*. "They begin to appear about the 16th of April; and for some time they in general pay no attention to the business of nidification: they play and sport about, either to recruit from the fatigue of their journey, if they do migrate at all; or else that their blood may recover its true tone and texture after it has been so long benumbed by the severities of winter. About the middle of May, if the weather be fine, the martin begins to think in earnest of providing a mansion for its family. The crust or shell of this nest seems to be formed of such dirt or loam as comes most readily to hand, and as tempered and wrought together with little bits of broken straws to render it tough and tenacious. As this bird often builds against a perpendicular wall without any projecting ledge under it, it requires its utmost efforts to get the foundation firmly fixed, so that it may safely carry on the superstructure. On this occasion the bird not only clings with its claws, but partly supports itself by strongly inclining its tail against the wall, making that a fulcrum; and thus steadied, it works and plasters the materials into the face of the brick or stone. But then, that this work may not, while it is soft and green, pull itself down by its own weight, the provident architect has prudence and forbearance enough not to advance her work too fast; but by building only in the morning, and by dedicating the rest of the day to food and amusement, gives it sufficient time to dry and harden. About half an inch seems to be a sufficient layer for a day. Thus careful workmen, when they build mud-walls (informed at first perhaps by this little bird,) raise but a moderate layer at a time, and then desist; lest the work should become top-heavy, and so be ruined by its own weight. By this method in about ten or twelve days is formed an hemispheric nest, with a small aperture towards the top, strong, compact, and warm; and perfectly fitted for all the purposes for which it was intended. But then nothing is more common than for the house-sparrow, as soon as the shell is finished, to seize on it as its own, to eject the

owner, and to line it after its own manner. After so much labour is bestowed in erecting a mansion, as nature seldom works in vain, martins will breed on for several years together in the same nest, where it happens to be well sheltered and secure from the injuries of the weather. The shell or crust of the nest is a sort of rustic work, full of knobs and protuberances on the outside: nor is the inside of those that I have examined smoothed with any exactness at all; but it is rendered soft and warm, and fit for incubation, by a lining of small straws, grasses, and feathers; and sometimes by a bed of moss interwoven with wool. As soon as the young are able to shift for themselves, the dams immediately turn their thoughts to the business of a second brood: while the first flight, shaken off and rejected by their nurses, congregate in great flocks, and are the birds that are seen clustering and hovering, on sunny mornings and evenings, round towers and steeples, and on the roofs of churches and houses. These congregations usually begin to take place about the first week in August; and therefore we may conclude that by that time the first flight is pretty well over. The young of this species do not quit their abodes all together; but the more forward birds get abroad some days before the rest. These approaching the eaves of buildings, and playing about before them, make people think that several old ones attend one nest. They are often capricious in fixing on a nesting-place, beginning many edifices, and leaving them unfinished; but when once a nest is completed in a sheltered place, it serves for several seasons. Those which breed in a ready-finished house, get the start in hatching, of those that build new, by ten days or a fortnight. These industrious artificers are at their labours in the long days before four in the morning; when they fix their materials, they plaster them on with their chins, moving their heads with a quick vibratory motion. They dip and wash as they fly sometimes in hot weather, but not so often as swallows. Martins love to frequent towns, especially if there are great lakes and rivers at hand. They are by far the least agile of the British hirundines; their wings and tails are short, and therefore they are not capable of such surprising turns, and quick and glancing evolutions, as the swallow. Accordingly, they make use of a placid easy motion, in a middle region of the air, seldom mounting to any great height, and never sweeping long together over the surface of the ground or water. They do not wander far for food; but affect sheltered districts, over some lake, or under some hanging wood, or in some hollow vale, especially in windy weather. They breed the latest of all the swallow-kind; in 1772, they had nestlings on to October the 21st, and are never without young as late as Michaelmas. As the summer declines, the congregating flocks increase in numbers daily, by the constant accession of the second broods; till at last they swarm in myriads upon myriads round the villages on the Thames, darkening the face of the sky as they frequent the aits of that river, where they roost. They retire, the bulk of them I mean, in vast flocks together about the beginning of October: but have appeared of late years in a considerable flight in this neighbourhood, for one day or two, as late as November the 3d and 6th, after they were supposed to have been gone for more than a fortnight. They therefore withdraw, with us, the latest of any species. Unless these birds are very short-lived indeed, or unless they do not return to the district where they are bred, they must undergo vast devastations somehow, and somewhere; for the birds that return yearly bear no manner of proportion to the birds that retire." See Plate LVIII.

HIRZHOLMEN, or HERTZHOLM, three small islands of Denmark, in the Cattegat, Lon. 10. 24. E. Lat. 57. 31. N.

HISINGEN, an island near the coast of Sweden, at the mouth of the Gotha, 16 miles long and 6 broad, containing seven parishes. Lon. 11. 48. E. Lat. 57. 45. N.

HISPA, in zoology, a genus of insects of the coleoptera order. Antennæ fusiform, growing gradually larger from each extremity towards the middle, situated between the eyes; thorax and elytra covered with protuberances or spires. There are twenty-six species, very few of which are natives of Europe.

H. ATREA, found in Britain, is all over of a deep unpolished black, and has the upper part of its body entirely covered with long and strong spires, which render it bristly like the shell of a chesnut. See Plate LXXVI. It bears its antennæ upright before it.

HISPALIS,

HISPALIS, in ancient geography, a town of Batica, in Hispania Ultra, now called Seville.

HISPANIA, in ancient geography, a country or kingdom of Europe, now called Spain; called Hesperia Ultima, by Horace, because the western-most part of Europe; also Iberia, from the river Iberus. Its name Hispania, or *Ἰσπανία*, is of Phœnician original, from its great number of rabbits. See SPAIN.

HISPANIOLA, or **ST. DOMINGO**, the largest of the Antilles or Caribbee islands, in the West Indies. It lies between 17° 55' and 20° of N. lat. and between 67° 35' and 74° 15' W. lon. It is 60 miles N. W. by W. of Porto Rico, 66 S. E. of Cuba, 135 E. N. E. of Jamaica, and 3,500 from the Land's End of England. The climate is hot, but not reckoned unwholesome; and some of the inhabitants are said to arrive at the age of 120. It is sometimes refreshed by breezes and rains; and its salubrity is likewise in a great measure owing to the beautiful variety of hills and valleys, woods and rivers, which every where present themselves. It is indeed reckoned by far the finest and most pleasant island of the Antilles, as being the best accommodated to all the purposes of life when duly cultivated. Its extent is estimated at 420 miles in length from E. to W. and 140 in breadth, where broadest, from N. to S. This island was discovered by Christopher Columbus, on the 9th of December 1492. It then formed five kingdoms, called Maqua, Marien, Higuay, Maguana, and Xaraguay, each governed by sovereigns called caciques. The Spaniards had possession of the whole of it for 120 years. This island, famous for being their earliest settlement in the world, was the first in high estimation for the quantity of gold it supplied. This wealth diminished with the inhabitants of the country, whom they obliged to dig it out of the bowels of the earth; and the source of it was entirely dried up, when they were exterminated, which was quickly done, by a series of the most shocking barbarities that ever disgraced the history of any nation. Benzon relates, that of two millions of inhabitants, contained in the island when discovered by Columbus in 1492, scarcely 153 were alive in 1545. For many years this island was possessed by the Spaniards and French jointly. It was afterwards ceded entirely to the French, but is now erected into an independent republic.

HISSAR, a district of Hindoostan, in Delhi: with its capital. The latter lies near the Surfooty, 112 miles W. N. W. of Delhi.

HISTER, in entomology, a genus of the coleoptera order of insects. Antennæ clavate, the club solid; the last joint compressed, decurved; head retractile within the body; mouth forcipated; shells shorter than the body, truncate; fore-shanks toothed, hind-shanks spinous. There are twenty-four species. The most common in Europe is *H. unicolor*, which is of a glossy coal black colour, and of a slightly flattened shape. It is often seen in the gardens, but its larva is unknown.

HISTORIOGRAPHER, [*ἱστορικὸς γραφεύς*], a professed historian, or writer of history. An historian, of all authors, spreads the most ample theatre; he erects the greatest tribunal on earth; for it is his office to sit supreme judge of all that passes in the world, to pronounce the destiny of the great ones of the earth, and fix their character with posterity; to do justice to virtue and worth, in bestowing eternity upon great and good actions, and fixing an everlasting mark of infamy on bad ones; to instruct all people and nations, and direct the conduct of ages; he therefore ought to be endowed with many great and uncommon qualifications. He must be a person of consummate knowledge of men and things, of sound judgement, uncommon sagacity and penetration, experienced in matters of state and war, of great integrity, firmness of mind, freedom of sentiment, and master of a pure, clear, nervous, and exalted style. An historian whose province it is to speak to kings and princes, to the great men of all ages and countries, and to be the common master and instructor of mankind, must not only write with purity, simplicity, and manly sense, but with dignity and elegance: he must reject all that is vulgar and low in style, make the majesty and sublimity of his expression comport with the dignity of the subject; must by an exact choice and propriety of words, a natural disposition of phrases, and a prudent moderate use of figures, give weight to his thoughts, force to his language, and imprint a character of greatness on all that he says. He must at the same time represent things with an air of gravity and prudence, and not give a loose to the heat of imagination.

tion, or vivacity of wit; but discreetly suppress every thing that shall seem idle, languid, and unprofitable, and give every thing that just figure and proportion which is consistent with propriety and decorum. He must endeavour at a noble simplicity of thought, language, design, and ordinance, and carefully avoid all profuseness of false conceit, strained expression, and affected pompousness so inconsistent with the gravity, dignity, and noble character, of history. In a word, he must write so as to be intelligible to the ignorant, and yet charm the wise; form and express such ideas as are great, and yet shall appear very common, and intermix no other ornament with his narration than what the modesty of truth can bear. He should be above the reach and power of hopes and fears, and all kinds of interest, that he may always dare to speak the truth, and write of all without prejudice; religiously observing never to abuse the public faith, nor to advance any thing upon common fame, which is always uncertain, but upon undoubted memoirs and faithful relations of such persons as have had a hand in affairs. He must always be upon his guard against the bias and affections of those who supply him with matter, and must not credulously give his assent to the historians that went before him, without enquiring narrowly into their character, and what influence they may have been under when they wrote, in order to make a just estimate of their weight and credit. An historian, as to his matter, should choose subjects great in themselves, and such as are worthy of public fame and remembrance; and should make himself so far master of his matter, as to be able to cast it into what form he pleases, and to strike upon all his subjects the colours they are naturally disposed to bear, in order to make his lessons profitable to posterity, by regulating the heart and spirits of men, animating them to great and virtuous actions by illustrious examples, and cautioning them against vice, folly, cruelty, and injustice, by laying open the fatal consequences resulting from them. The course of his narration must proceed in the order of time in which the facts happened, in a pure, grave, uninterrupted series, such as may not improperly be compared to a great river flowing with composed majesty and stately smoothness; and when it falls in his way to introduce little occurrences, they must be so artfully interwoven with the great, in the thread of the narration, as to offer a seasonable entertainment and relief to the reader from the fatigue that too sedulous an attention to the great requireth. He must also observe great judgement in the ordinance and disposition of events and their circumstances, so as to interest the reader, and let him into all his thoughts and views, by making his persons act as their character and temper inclined them; discovering their manners, sentiments, designs, motives, and operations, as they really stand in a necessary dependence upon each other, and with so natural a connection, as to shew nothing out of its place. His transitions, in which consists the great art of narration, and one of its principal beauties, must be natural and easy, arising from the difference of subject rather than expression. He must make a wise and judicious choice of circumstances, such as are proper to enlarge and improve the ideas of things, and to strike that light and colour upon them which most easily attracts belief, and engages the mind; and must for that purpose always observe a due mixture of great and little circumstances, neither of which must be carried beyond nature, or be so minute, low, or frivolous, as to debase his subject. He must not only recite the bare events and actions of men, but also lay open the motives and principles from which they took their rise, and upon which they proceeded to their final issues. He must lay open the hearts of the actors, let his reader into the most important secrets of their councils and designs, and oblige him with a sight of those secret springs which move them to enterprizes, and of the causes of their success or miscarriage. He must be very sparing and cautious in the use of descriptions, which are to be introduced so far only as they serve to illustrate things that are essential to the main subject, and to enliven the narration; and even in that case they must be succinct and elegant. The frequent use of harangues are disapproved of by many judicious persons; for these long formal harangues of generals to their soldiers, when in the presence of the enemy, and ready to enter upon action, which we find in many historians, are undoubtedly not only unnatural and improbable, but contrary to the truth of history. Nevertheless, a short speech suited to the subject, made by a person of eminent character, has its proper beauty, and animates a narration. A judicious historian ought

ought not to admit any portraits into his work but those of the greatest persons, and such as are principally interested, and have the chief hand in affairs, and these must be real, natural, and truly resembling their originals; expressive of their genius, the qualities of the head and heart, rather than descriptive of the external form of his personages. When such are finished with a masterly hand, with true judgement and success, they are not only great ornaments and embellishments in history, but of use to strip the hearts of men of their disguises, to lay open all their secret folds, and disclose the real springs of actions. It is a great fault in an historiographer to abound too much in reflections of his own; he therefore must not turn philosopher or moralist indifferently upon all occasions; for every man desires to be free in his judgement of the facts represented to him, and the consequences he is to draw from them, in which consists the greatest pleasure of the reader. But if an author should throw in, or mingle reflections of his own,

with his story, they must be such as arise naturally from the subject, and contain a great and noble sense in a few words; they must not be too finely spun or studied, nor have more brightness than solidity, but appear rather to be the reasoning of a wise statesman than the affectation of a declaimer; nor must they be too frequent, or too loose and disjointed, but be enamelled in the body of the work. Digressions, if made with judgement, and not too wide and foreign from the subject, have also their proper grace and ornament in history; as they give an agreeable variety to the narration, and relieve the mind of the reader; but they must be introduced by the historian with an artful hand and great address; they must bear an alliance and connection with the purport of the history, and their length must be proportionably greater or less, as they are more nearly or remotely allied to the capital point of the story.

END OF VOLUME II.

*Cupola or Dome
constructed without Centering*

Dendrites

Draco volans: Flying Dragon.

PISCES.

Coryphæna rupestris.

Cottus Cataphractus.
Mailed Bull Head.

Diodon atinga.

Cyclopterus lumpus
Lump sucker.

Cyprinus latius.

Delphinus delphis. Dolphin.

Cyprinus carpio.
Large scaled Carp.

Diodon hystrix.

Exocoetus ciliatus.

Gymnotus electricus.
Electrical gymnote.

Labrus formosus. Blue finned Labrus.

Lophius histrio.
Harlequin fishing frog.

Gobius lanceolatus. Lance tailed goby.

Mullus Ruber.

Monodon the Narwhal.

Phobastria immutabilis: Hooded Dido.

Diomedea Exulans: Wandering Albatross.

Falco chrysaius: Golden Eagle.

Emberiza Nivalis: Snow Bunting.

Emberiza hortulana: Cirl Bunting.

Ossifragus: Osprey.

Falco litho fulco: Stone Falcon.

Hirundo Rustica: Swallow.

Glaucola Austriaca: Austrian Pratincole.

Fulica aterrima: Greater Coot.

Hirundo Ureica: Martin.

Fringilla Montana: Tree Sparrow.

Fringilla Linaria: Lesser red pole.

Lanius Antiquarius: The Antiquan Shrike.

Loxia pensilis: Pensile Grosbeak with its Nest.

Larus Parasiticus.

Loxia Oriz: Grenadier Grosbeak.

EUPHORBIA.

Ferula assa foetida: *Assa foetida*.

Hippomane Mancinella.

Hedysarum gyrans.

Geoffræa.

Holcus Sorghum.

Jatropha Elastica.

Guaiacum officinale.

Jatropha Janipha.

Erinaceus Malaccensis: Malacca Hedge hog.

Didelphis volans:
Flying opossum.

Erinaceus Europæus:
Common Hedge hog.

Didelphis maculata:
Spotted opossum.

Didelphis gigantea: Kangaroo.

Didelphis murina.

Dipus Aegyptius: the Egyptian Jerboa.

Equus Caballus: Race Horse.

Equus Caballus: Cart Horse.

Equus Zebra: Zebra.

Equus Asinus: Ass.

Elephas maximus: elephant.

Crotalus horridus: banded rattle snake.

Haliotis tuberculata.

Haematites wiformis.

Helix sepium.
